though it is possible to distinguish broadly between three main types within the group, there is no hard and fast line of demarcation between them, and the existence of transitional forms is sufficiently frequent to suggest that specific characters are subject to change with environmental conditions. His conclusions are based on a study by a number of different methods of more than 300 strains collected from different parts of the world. He found that besides the existence of three main groups—bovine abortus, porcine abortus and melitensis—with their subsidiary rough para-abortus and paramelitensis derivatives, there exist within each group a number of subgroups containing transitional strains, which frequently are associated with some particular geographic location. The author suggests that members of the Alcaligenes group are relatively labile and respond readily to environmental changes. How far this peculiar lability is responsible for their power to adapt themselves to a number of different hosts and for their varying pathogenicity is for the future to decide. In view of the existence of numerous subgroups, it is unjustifiable, in the classification of individual Alcaligenes strains, to rely on any single method of examination. Every strain should if possible be examined for carbon dioxide sensitivity, for hydrogen sulphide formation, for growth in the presence of thionine basic fuchsin, methyl violet and pyronine, and for antigenic structure. If reliance is placed on but one or two methods, some strains are bound to be classified wrongly and erroneous conclusions drawn as to the pathogenicity of the group to which they are allocated.

Five Hundred and Ten Strains of Corynebacterium Diphtheriae.—In a study of 510 strains of *Corynebacterium diphtheriae*, Carter has found it possible to divide 99 per cent in three types by colony appearance, the fermentation of starch and the appearance in broth, as described by the Leeds workers. In an area in which diphtheria is mild a grave form of *C. diphtheriae* is rare and its place is largely taken by the intermediate type, which however is less virulent but causes paralytic and albuminuria to about the same extent as the grave type when the latter is the chief infecting type. The different types of *C. diphtheriae* have defined characteristics and are stable in these characteristics. Diphtheria due to the intermediate type responds to antitoxic serum in an average way, as with a large preponderance of cases due to this type the case mortality rate is much below the rate in areas in which the grave type predominates.

Azo Dyes and Coagulation of Blood.—Huggett and Rowe examined some azo direct dyes for their effect on the coagulation time of blood. Inhibition of blood clotting is a property shared by a number of these dyes. The best are all disazo direct dyes prepared from tetrazotized diamines coupled with ammonaphthol sulphonic acids. The most efficient anticoagulants obtained were chlorazol fast pink BKS, its isomer S. D. 2 and an exceptional specimen of Color Index No. 518, marketed as Chicago blue 6B. Chemical impurities in the dye influence the action, so that purification is essential in any dye which is being used for this purpose.

*Toxicity of Carbon Tetrachloride and Its Allied Halogen Compounds J. W. Tomb and M. M. Helmy —p. 334

Toxicity of Carbon Tetrachloride.—Tomb and Helmy state that carbon tetrachloride and its closely allied halogen derivatives of the aliphatic hydrocarbons are capable in therapeutic doses of causing fatal intoxication accompanied by acute degeneration of the liver. Fatalities from carbon tetrachloride intoxication occur much more frequently among children and adolescents than among adults, probably owing to an inefficiency of calcium reserves in the young. Immediate poisoning by carbon tetrachloride in therapeutic doses is generally associated with disease of the liver or with other clinical contraindications. Delayed poisoning by carbon tetrachloride in therapeutic doses is generally due to nonelimination of the drug from the intestinal tract, in or without association with clinical contraindications. It can be obviated, when the liver is healthy, by rapid and free evacuation of the drug. Fatal intoxication by carbon tetrachloride in Egypt has been found to be closely associated with ascariasis. Ascariasis in such cases would appear to act in two ways: (1) by causing a mechanical obstruction to the action of the saline purgative and increased absorption of the drug when worms are numerous in the intestine, through 'clumping' of the worms, or (2) by diminishing the natural resistance to the drug in cases in which clinical contraindications already exist, either through toxins produced by the worms or owing to the unsatisfactory economic conditions and consequent low state of general nutrition which ascariasis implies. When intoxication by carbon tetrachloride has manifested itself, intensive treatment by intravenous injections of calcium gluconate (Sandoz) is capable of saving life, provided the drug has been thoroughly evacuated from the intestinal canal. The traces of carbon disulphide found in medicinal carbon tetrachloride are of no toxicologic significance.

Hospital Administration Abroad A. G. Stephenson —p. 653

Synovial Sheaths and Fascial Spaces of the Hand W. E. A. Hughes Jones —p. 658

Uterine Conditions Treated with Radium.—Porter treated thirty patients presenting myopathic and myomatous uterine disorders with radium. Of these only one was subsequently operated on and only one required a second dose. The remainder have all been cured of their principal complaint, menorrhagia, while those suffering from fibromyomas all show a decrease in the size of the tumor since treatment. As a routine from 30 to 40 mg. of radium element is used, generally two tubes of 20 mg. of radium each placed end to end. These tubes have a screening of 1 mm. of platinum and are placed in a rubber tube (2 mm. thick), this provides the secondary filtration for the radium. The applicator so formed is approximately from 4 to 5 cm. in length, has about the thickness of an ordinary lead pencil and has a silk thread secured to its distal end. In all cases the urine is tested, a full blood count is made and a Bordet test is performed. Under general anesthesia and after a particular vaginal cleansing a careful bimanual examination is carried out. Dilatation of the neck of the uterus follows (if a fibroid or cervical polyp is encountered it is removed at this stage). The uterus is curetted. The scrapings obtained are submitted to pathologic examination. The applicator containing the radium in tubes is then inserted into the uterine cavity and pushed right up to the fundus, so that no portion protrudes. The silk thread attached reaches to the vulva. The vagina is then firmly packed with iodoform gauze to prevent the applicator from slipping down into the vagina and to serve as an extra protection to the bladder and the rectum. The labia are drawn together with a single

superficial catgut suture to retain the gauze. At the end of the time determined on, the radium contained in its rubber sheath is easily removed (without an anesthetic) by gentle traction on the attached silk thread. The dosage to be employed is determined by a multiplication of the number of milligrams of radium element used and the number of hours during which it is applied, the dose being given in milligram-hours of radium element; for example, 40 mg of radium used for fifty hours equals 2,000 milligram hours of radium element.

Production of Diphtheria Toxin—Hosoya and his associates state that the toxin produced in the medium containing Chapoteaut peptone, Difco-proteose-peptone, Witte peptone and Teruuchi peptone, respectively, as the source of nitrogen, and adjusted to pH 7.8 by the addition of dextrose and salts, is strongly toxic in the first two peptones and is extremely weak in the last two. The formation of strong toxin was found in the basic medium containing the element of Chapoteaut peptone, which is soluble in pure methyl alcohol as the source of nitrogen. Examination of the strength of the toxin in the liquid medium prepared by adjusting it to pH 7.8 by the addition of various amino acids and other nitrogenous substance to the foregoing basic medium showed that glycine, phenylalanine, tyrosine, sodium aspartate, histidine, arginine, lysine, tryptophan, glycylglycine, creatine, creatinine and carnosine have respectively no favorable influence on the production of toxin. The addition of cystine or cysteine to the basic medium remarkably promotes the proliferation of the bacillus. In case the basic medium is adjusted to pH 7.8 by the addition of cysteine hydrochloric acid in the proportion of 0.05 per cent, a strongly potent toxin is produced at the early period of cultivation. Cystine also has a favorable influence on the production of toxin. Methionine and adenylthio-methyl peptone have no influence on the production of toxin in the experiment in the basic medium. Although the addition of cysteine to the medium containing Witte peptone as the source of nitrogen causes the production of a fairly strong toxin yet in the medium obtained by adding cysteine to Teruuchi peptone the bacillus proliferates abundantly but almost no toxin is produced and the reaction of Ramon does not appear. Although no toxin was produced in the medium containing as the source of nitrogen the decomposition product resulting negative in the biuret reaction and lead sulphide reaction by hydrolyzing two hours at two atmospheric pressures the methyl alcohol soluble fraction of Chapoteaut peptone

saturated with solution of baryt, yet in the medium supplemented with cysteine or cystine fairly strong toxin is produced, showing the highest record of the strength of the toxin produced in the biuret reaction negative medium.

Gangrene of Fingers Following Local Regional Anesthesia—Lambert and Snyers state that local regional anesthesia appears contraindicated in infections of the fingers. It is best to substitute for it as frequently as possible anesthesia by freezing. Nevertheless, when administered for ingrown nails without local infection or for subungual foreign bodies without apparent infection, only a less concentrated solution without epinephrine is injected in exceedingly small amounts so as to reduce the factor of blood stasis. In certain cases it is advantageous to practice a strictly local anesthetic infiltration. After operation, active and immediate mobilization of the finger that has been operated on should be promoted in order to avoid circulatory stasis. If return of sensation is delayed it is wise to administer alternating baths and massage. Coarse manipulations should be avoided. The authors state in concluding that gangrene of the fingers after local regional anesthesia is the result of thrombophlebitis and not of epinephrine vasoconstriction. Arterial obliteration is not primary but secondary to retrograde thrombosis. Two conditions are indispensable for the production of the thrombotic process: mitigated infection and blood stasis. The injected anesthetic solution acts as a factor in the circulatory stasis which increases with the concentration of the solution and the presence of epinephrine.

Gold Therapy in Pulmonary Tuberculosis—Soglia and Tosi treated twenty-four patients with gold therapy, twelve of whom were given intravenous injections of gold sodium thio-sulphate (sanocrysin) in a 5 per cent double distilled aqueous solution. To avoid secondary disturbances the authors began with small doses, which were gradually increased according to the tolerance of the patients. The first dose was 0.05 Gm, the second, seven days later, 0.1 Gm, and the doses were increased gradually to 0.5 Gm. Never more than 5.6 Gm of the substance was administered in the course of treatment to a patient. Six patients were given intragluteal injections of sodium gold thiopropanol sulphonate (allochrysin) in doses of 0.05 Gm. After from four to five administrations the dosage was raised to 0.1 Gm and eventually to 0.2 Gm. The other six patients received intramuscular injections of a colloidal gold salt (collaurum) in doses of 2 cc on alternating days. A rest of from ten to fifteen days between the series of treatments was allowed to all patients. Immediately after the first injections the patients evinced a feeling of general well being and a temporary and slight decrease in weight. While many patients showed a modest rise in temperature, the thermic curve of a few was not affected. The sputum was reduced in quantity and contained less bacilli. Certain secondary disturbances originated from the rapid diffusion in the organism of microbial poisons deriving from the destruction of the tubercle bacilli. These are principally albuminuria, dermatitis and pruritus, nausea, vomiting and diarrhea, stomatitis and conjunctivitis.

are occasionally observed after administration of strong doses. Of the twenty-four patients, five were cured, eight improved, four declined and seven remained unaffected. The authors maintain that gold therapy, if carefully administered, may show good results, but they believe that in advanced and serious cases it is useless to stimulate an organism that cannot protect itself. Generally in these cases toxic factors exist which are only accentuated by the introduction of gold. The authors state in conclusion that gold therapy is complementary to institutional cure and collapse therapy and is definitely not a specific cure for tuberculosis.

Action of Thyrotropic Hormone of Anterior Hypophysis—Doderlein reviews the literature on the subject and relates studies on the thyrotropic action of anterior hypophyseal preparations extracted from the urine. He found their action on the thyroid extremely variable and thinks that, although they occasionally have a thyrotropic action, they are unsuitable for exact studies investigating the influence exerted by the anterior hypophysis on the thyroid. He points out that there is general agreement among investigators that anterior hypophyseal extracts not of urinary origin but prepared from hypophyseal tissue influence the thyroid. He describes the thyroidal changes produced with an anterior hypophyseal extract and those produced with the purified "thyrotropic hormone." He found that the latter exerts a more intense action. He points out that, since the discovery of the thyrotropic action of the hypophysis, experiments have been made to utilize this action for therapeutic purposes by using it in the place of thyroxine. In patients having myxedema and congenital cretinism the thyrotropic hormone produced a considerable increase in the iodine content of the blood and, in obese persons, a reduction in weight, but in the latter condition it was less effective than thyroxine. The author relates experiments that he conducted in order to determine whether the thyrotropic hormone of the anterior hypophysis passes the placenta. He administered the thyrotropic hormone to pregnant guinea-pigs and later examined the thyroids of the young. He noted signs of activation in the thyroids of the new-born animals, and from this he concludes that the placenta is permeable for the thyrotropic substance of the hypophysis.

Brenner Tumors—In the Charite women's clinic, examinations led to the discovery of Brenner's tumors coincidental with other disorders, twice within one year. Freund relates the clinical history of these patients and describes the histologic aspects of the tumors. In the first patient, a voluminous pseudomucinous tumor was found, which belonged to group 2 of Meyer's classification. The second patient, whose uterus had been extirpated on account of an adenocarcinoma, had in the ovary an isolated solid nodule about the size of a pea. This nodule was found to belong to group 1 of Meyer's classifica-

tion. The diagnosis was based on the characteristic foci of epithelial cells with and without central clefts, which may be lined with mucous epithelium, and on the surrounding fibrous tissue. Former studies on these tumors have revealed that they have neither clinical nor biologic significance on account of their generally small size and benign character and because hormonal functions are absent. Scientific interest has therefore been concentrated on the histogenesis. According to Meyer, the Brenner tumors belong to the structures that develop from the derivatives of the coelom epithelium, just as do the solid cell nodules underneath the serosa of the tubes or the Walthard cell foci in the infantile ovarian cortex. These entirely indifferent cell complexes have, as all coelom derivatives, the capacity to develop in the one or other direction, depending on local or general influences (hormones, nutrition, circulation), and form abnormal structures in the region of the adnexa. If the Walthard cell foci retain their indifferent character in the course of their blastomatous development, the solid Brenner tumor develops in which nests of epithelium are embedded in the fibrous connective tissue. In the center of the nests there may be hollow spaces and cysts with indifferent cylindric or mucous epithelium. These formations, the macroscopic aspects of which resemble those of fibromatous nodules, belong to the first group of Brenner tumors (solid tumors with or without cysts). If the differentiation of the cell foci tends primarily in the direction of cyst formation, the second type of Brenner tumor develops in which the cyst formation reaches such an extent that a cystoma appears with an intramural Brenner nodule with or without pseudomucinous epithelium. Since Orthmann was the first to call attention to this type of tumor and not Brenner, the author agrees with Plaut who suggested abandoning the eponymic term and applying the anatomic term of benign mucinous fibro-epithelioma.

Eclampsia, a Hypophyseal Disorder—Fauvet presents a comprehensive study on this problem. He shows that in the edematous nephrotic and eclamptic syndrome which develops in pregnant, parturient and lactating women disturbances in the water exchange and in the vascular system predominate. He demonstrates that it is possible to explain these manifestations by experiments with the hormones of the posterior lobe of the hypophysis. By administering extracts to animals, he was able to produce all the symptoms, except the eclamptic attacks. Even the pathologic-anatomic changes became manifest. He points out that the pregnant organism even if healthy, undergoes changes which indicate an increased function of the hypophyseal system. In comparing these manifestations with disease processes of hypophyseal origin in nonpregnant persons a considerable degree of identity could be ascertained. It is possible that labor pains are induced by a hypophyseal hormone but definite proof is still lacking. Experiments demonstrated that the hormones of the anterior hypophysis are essential in the development of lactation and apparently also for the first development of the new-born. Other authors (Hoffmann and Anselmino) furnished evidence that the hypophyseal substances controlling the water exchange and the blood pressure are present in increased quantities in the blood of women suffering from eclampsia. This led to a causal and apparently successful therapy, and the author thinks that medical science is justified in considering the edematous, nephrotic and vasopressor components of the eclamptic syndrome a disturbance that is produced by a pathologic hyperfunctioning of the hypophysis.

Artificial Endometriosis—Schmid shows that by the production of an artificial endometriosis, namely, the transplantation of the uterine mucosa into the vagina, a regular menstruation with external discharge can be produced. Observations on nineteen patients proved that the procedure is simple and without danger. The method makes it possible for younger women in whom the uterus is absent but who still have functioning ovarian tissue to continue to menstruate. The author points out that this may prevent psychic depressions in women of the child-bearing age who have to undergo extirpation of the uterus. Moreover the artificial endometriosis also has the detoxicating effect of menstruation stressed by Aschner. Several objections that could be raised against this method are discussed and largely refuted.

Lipophagic Granuloma Formations in Mammary Gland—Bartsch states that lipophagic granulomas are granulation tissue formations which develop in connection with localized necroses of the subcutaneous fat tissue. The fat, which is freed and saponified by the granulomas, acts as a foreign body, inducing a reactive transformation in the sense of a foreign body granuloma. Lipophagic granulomas are caused mainly by trauma, in this matter, however, not only mechanical but chemical and physical factors come into consideration. Because of clinical appearances, lipophagic granulomas are often diagnosed and treated as true malignant tumor formations. The possibility of mistaking them for cancer is due mainly to the alterations in the mammary glands. To treat lipophagic granulomas correctly, it is necessary to consider them from a differential diagnostic point of view and do a biopsy before performing a mutilating operation.

Effect of Inhalation of Carbon Dioxide on Blood Coagulability—Marx investigated the effect of carbon dioxide inhalation on the blood coagulability and bleeding time in man and animals. He found that, if guinea-pigs were kept from three to five minutes in an air mixture containing 5 per cent by volume of carbon dioxide, the blood coagulation time is diminished by 33.6 per cent and the bleeding time by 29 per cent. In healthy people after from four to five minutes of continuous inhalation of this air mixture there was a 45.3 per cent diminution in the blood coagulation time and a 68.2 per cent diminution in the bleeding time. Five minutes later these values showed a diminution of 53 and 70 per cent, respectively, and after a quarter of an hour still showed 26.5 and 25 per cent, respectively. In comparison with this, the number of thrombocytes fifteen minutes after inhalation showed a rise of 22.7 per cent. The blood coagulation time in a cholemic dog after ten minutes of continued inhalation was reduced about 52.8 per cent, after five minutes about 44.5 per cent and after fifteen minutes about 29 per cent. The bleeding time correspondingly showed a diminution of 29.6, 16 and 28 per cent, respectively. After repeated inhalations, the coagulation time sank to 39.5 per cent and the bleeding time to 30.8 per cent. In patients suffering from icterus with retarded blood coagulability and bleeding time, a diminution of the former to 44.7 per cent may be observed after fifteen minutes, while that of the latter may be found to be 39.8 per cent. On the basis of his experiments, the author recommends from four to five minute inhalations in already existing parenchymatous hemorrhages or as an effective prophylactic. As such it should be administered before the operation, which presumably is accompanied by abnormal parenchymatous hemorrhages.

Serum Administration in Gas Edema—Angerer states that gas edema serum is generally administered as an aid to surgical treatment. The author cites the difficulties encountered in the clinical evaluation of the serum, among them the difference in virulence of the bacilli, in the general condition of patients and in the infected tissues. In animal experimentation the gas edema serum has been both prophylactically and therapeutically effective. In man these successful results have not yet been obtained. According to some writers, the most frequent cause of gas edema in man is Fraenkel's bacillus. The author experimented on 119 guinea pigs with pure and mixed

cultures of Fraenkel's bacillus. To each guinea-pig of average weight he gave 2 cc of serum against an average lethal dose of Fraenkel's bacilli. A local gas edema appeared in the course of infection in all animals, and the effect of the serum became evident in the further course of the disease. On the second or third day after infection the animals successfully treated with the serum gradually recovered from their severe general malaise. In connection with the improvement in the general condition, alterations in the local lesion were observed. In most of the surviving animals, especially in those treated locally, breaking down occurred at the site of inoculation. After several days the abscess pierced the skin and later resulted in widespread necrosis, which was cast off and was quickly replaced by abundant granulation tissue. The author found that in animal experimentation a specific effect of the gas edema serum can be demonstrated in contrast to gas gangrene serum. The development of a local gas edema could not be prevented in any experimental animal through the administration of serum. The serum effect manifests itself so far as the animals withstand the serious general malaise. Besides this, spreading of the gas edema could be hindered in many ways through local administration of serum. Several favorable results have been obtained in the application of nonspecific serum in animal experimentation against infection with Fraenkel's bacillus. The earlier large quantities of serum are administered locally in man, the sooner favorable results are to be expected. The brief time of incubation and the difficulty of proving when the disease begins make it difficult to judge whether in the individual case the serum was given prophylactically or therapeutically. The author states in conclusion that gas edema serum in animals has a specific effect against infections with Fraenkel's bacillus in simultaneously prophylactic and therapeutic administration and that when the serum is locally administered at the focus of infection it produces a more favorable effect than when administered elsewhere.

Primary Pulmonary Cancer—Sattler stresses the polymorphism of pulmonary cancer, which becomes manifest not only in the pathologic-anatomic but also in the symptomatologic aspects. Occasionally the cancer presents the symptoms of an attack of pneumonia, in other cases those of a chronic, lobular infiltration, particularly of the upper lobe, and in still others it appears under the aspects of a pulmonary abscess or simulates pulmonary gangrene. There are also cases in which the cancer presents itself with the symptoms of a pleural exudate, in which case one may speak of a pleural form of pulmonary cancer. The hemorrhagic character of the exudate is particularly suggestive of cancer, especially in the absence of a tuberculous etiology, and a high degree of coagulability is also indicative of cancer. Pulmonary cancer may present the symptoms of a mediastinal tumor, if the primary tumor remains small and the mediastinal metastases present an intensive growth. Finally, it may manifest itself with the symptoms of a fibrous ulcerous phthisis. In addition to these symptomatologies, pulmonary cancer may appear with slight or indefinite symptoms on the part of the respiratory organs. In the diagnostic methods it is advisable to differentiate between those that definitely establish cancer and those that have only a character of probability. A definite proof of the presence of cancer is the demonstration of tumor cells in the pleural exudate in the sputum or in the material obtained by exploratory excision. Bronchial cancer may be detected by bronchos-

copy. The author discusses the significance of bronchostenosis and of intrathoracic compressions. After discussing bronchography, he gives a statistical report of the symptomatology of fifty-seven cases. He points out that the condition is much more frequent in men than in women and that it occurs most often during the fifth, sixth and seventh decades of life. He gives the frequency of the various locations of pulmonary cancer.

Treatment of Gonorrhea in Posterior Urethra with Swelling Suppositories Containing Silver. C. Carrié—p 1817

Demonstration of Gonococci and Simple Culture Method.—Szilvasi shows that the examination of a fluid secretion that is obtained after the urethra has been flushed with the urine is more satisfactory and reliable than the examination of the thick pus. To obtain the material for microscopic examination, the author lets the patient urinate and then inserts a platinum loop into the anterior portion of the urethra and obtains a secretion that is readily spread out. After staining according to Gram's method, a striking picture is seen. Between monocytes and isolated threads of mucus, the gonococci are found in peculiar arrangements, in the form of coils, of clusters or of wreaths or caps. The fact that an intensely stained zone surrounds the individual gonococcus enhances the peculiarity of the picture. Illustrations show that, if the specimen is obtained as the author described it, the gonococci always occur in large quantities and in the characteristic groups and the author thinks that it cannot be doubted that this is the primary manifestation of the gonococcus for the microscopic picture obtained from the pus drop cannot be compared with it. He lists the advantages of the one and the disadvantages of the other method. He shows that this method of obtaining the specimen of the urethral secretion is advantageous also for the culture of the gonococcus, which used to be rather difficult when the thick pus was used. He applies the secretion to the culture medium not in streaks but in dots and then finds the gonococci on the margin of the dots. The fact that in the pus the majority of gonococci are either destroyed or impaired and that the phagocytic leukocytes contain other microorganisms is probably the reason why the demonstration and culture are less successful when thick pus is used than when the secretion is used as the author obtains it.

Acroangrene in Malaria.—After reviewing a case from the literature, in which gangrene of the toes set in after a malarial infection, Zimmermann relates a case of his own observation. Because of mental aberrations and the positivity of all syphilitic seroreactions in the blood and the cerebrospinal fluid, the patient was inoculated with tertian malaria. The course of fever was of a mixed tertian type. After the sixth attack of chills a decrease in the blood pressure became noticeable, the maximal pressure going under the 100 mark. The pulse became soft and the patient's condition declined noticeably. The skin and mucous membranes became pale, and after the tenth attack of chills the lower portions of the nose and the outer margins of the ears became cyanotic. The tip of the

nose and a portion of the cartilaginous nasal septum became necrotic and fell off. The left helix recovered, while on the right helix a suppurative development on the basis of the tissue impairment, and small portions of the tissues were cast off. The gangrenous process was accompanied by a severe anemia, the erythrocytes going below the two million mark. On the basis of tests and of the earlier history of the patient, the author thinks that the gangrene was of the vasoneurotic type. He points out that patients may become greatly weakened by malaria treatment. This may be due to a greater virulence of the malarial strain or to the lack of resistance in the patient. Patients with low resistance and those who have aged prematurely are particularly in danger. A labile sympathetic nervous system, by way of the vasomotors, may impair the vessels and may lead to trophic disturbances, particularly of the extremities. The reduction in the blood pressure may have been a contributory factor in the development of the gangrene, and for this reason the author recommends that it should be carefully controlled in the course of malaria therapy. Disregarding the cosmetic impairment, the patient has considerably improved.

Postdiphtheric Facial Paralysis.—On the basis of observations on 330 cases, Seckel was able to corroborate the frequent appearance and disappearance of the facial phenomenon in all forms, but particularly in the severest forms of diphtheria. The incidence was about like that reported by Borrino (16 per cent). Unilateral facial paresis, however, is much rarer after the generally bilateral pharyngeal diphtheria. The author observed it only four times (once without preceding facial phenomenon) in 330 cases (1.2 per cent), but this percentage is high in view of the fact that other authors observed not a single case in still larger materials, and another one only fifteen in more than 6,000 cases. Three of the cases of postdiphtheric facial paresis with the facial phenomenon, which were observed by the author are reported. In the first two cases the facial phenomenon was at first negative, and in the third case it was positive on the third day. The severity of the phenomenon varied in the three cases from a slight twitching of the corner of the mouth to a twitching of the entire half of the face. The facial paresis was of course absent in all three cases during the first stage and a complete facial paralysis did not develop in any of them. The mild form of facial paresis became manifest only in the course of emotional excitements (laughing, crying and so on), but in the severe forms it could be perceived by a lay person even when the face was calm. The author differentiates three stages in the course of postdiphtheric facial neuritis. 1 The initial or irritative stage, during which the facial phenomenon is positive on both sides. Pains may develop on the side that later develops a paresis. 2 The preparietic stage, during which the facial phenomenon that during the first stage had become positive becomes weakened or negative on the side that later becomes paretic. On the contralateral side, the Chvostek sign remains unchanged or increases. The first two stages last from sixteen to twenty-six days. 3 The paretic stage. On the side on which the facial phenomenon has become weakened or negative, the paresis develops. The Chvostek sign of this side occasionally is positive, irrespective of the paresis. The facial phenomenon of the other side may become weaker or entirely negative. This signifies a return to normality. If, after from two to six weeks, the facial paresis disappears, the Chvostek sign is negative on both sides.

Treatment of Anemias with Irradiated Own Blood.—Fervers studied the effect of ultraviolet irradiation of the blood on animals and human subjects. His first experiments were made with a quartz tube that was inserted into the vascular system and irradiated while the blood passed through it. When this procedure was followed, the blood was hardly at all influenced and another method was adopted. The blood (20 cc.) is withdrawn from the vein of the arm and is mixed with a 5 per cent solution of sodium citrate in a ratio of 1:4. In a sterile petri dish it is exposed for from five to ten minutes to the light of a quartz lamp at a distance of from 20 to 30 cm. This irradiated blood is then injected intramuscularly. The result is that the erythrocyte values increase considerably, much more than is the case after simple autohemotherapy. Intravenous reinjections have the same effects as the intramuscular ones. In persons with normal erythrocyte values the increase

produced with the injection of irradiated blood was 0.7 million. In patients with subnormal erythrocyte values (secondary anemia) the increase was greater, averaging 1.2 millions. The increase was unusually rapid. It was noticeable after half an hour and reached a maximum in from three to four hours. This maximum persisted for from one to two days, after which time there was a decrease. However, repeated injections always drove the values up again, so that in a patient in whom great loss of blood had reduced the erythrocytes to 1.4 millions a normal status of 4.8 millions was reached after three injections in the course of two weeks. The general condition of the patient improves together with the blood status. In the action mechanism of the injections of irradiated blood the spleen seems to play an important part, for in the absence of the spleen there was practically no increase in the erythrocytes. Animal experiments seemed to indicate that the injection of irradiated blood not only increases the number of erythrocytes but also prolongs their life. The author had only limited experience with primary anemias, but he noted a favorable effect on lymphatic leukemia and on pernicious anemia in the few cases he observed. Other diseases in which he observed favorable effects from injections of irradiated blood were exophthalmic goiter and asthma.

Freund-Kammer's Cutaneous Reaction for Diagnosis of Carcinoma—Kammer calls attention to this method, which is essentially an intracutaneous vaccination with the carcinoma fatty acid that is extracted from the intestinal contents. It was first described in 1931 and since then has been corroborated by several other investigators. This paper reports the result of the test on 261 patients in whom the presence of carcinoma had been established histologically, and on 176 persons without carcinoma. Of the first group 252 gave a positive reaction, that is, the result of the test was correct in 96.5 per cent of the cases. Of the 176 persons without carcinoma, 150 gave a negative reaction, that is, in this group the reaction was 84.8 per cent correct. Denk, who is one of those who have tested the reaction, thinks that the positive reactions in persons without carcinoma (15.2 per cent) may indicate a predisposition to carcinoma.

Demonstration of Photodynamic Substances in Urine—Perutz and Lustig point out that the demonstration of photodynamic substances in animals and plants made it appear probable that certain disorders in animals and in human subjects are of photodynamic origin. To this group of diseases, in which the action of light could be demonstrated, belong the buckwheat exanthem of white cattle and of sheep and the clover disease in human beings, hydroa aestivale, Hutchinson's summer prurigo, several other photodermatoses and perhaps pellagra. In hydroa aestivale porphyrin could be demonstrated as the photodynamic sensibilizer, while in the other disorders the nature of the photodynamic sensibilizer is not yet known. The elimination of the photodynamic sensibilizers takes place largely through the urine. In hydroa aestivale the porphyrin

or porphyrinogen can be demonstrated by means of the spectro-scope. It was the authors' aim to find a simple method for the demonstration of photodynamic sensibilizers in the urine, irrespective of their nature. They consider the direct demonstration of a photodynamic action as the simplest means. For this purpose they utilized the influence of light on photographic, glossy, daylight paper saturated with the urine that is to be tested. Two strips of this paper, which are identical in size (26 cm.), are half immersed into the urine to be examined and into the control urine. The control urine should have the same color as that which is to be tested, and a similar specific gravity. After one minute, both strips are taken out and exposed to light (sun or quartz lamp). As soon as the non-immersed portion of the paper has become browned, the light exposure is interrupted and the colors of the papers are compared. It was found that the urine which contains a photodynamic sensibilizer always produces a darker coloration. In order to avoid mistakes, it is essential that the patients do not receive medicaments (acriflavine hydrochloride, for instance) that would cause the passage of fluorescent substances into the urine.

Acrocyanoses—Benatt and Honighaus show that the dilated subpapillary plexus, in which there exists stasis and which is present in mottling of the skin and other forms of acrocyanosis, has a functional relation to the circulation. They studied the action on acrocyanosis of saline baths containing carbon dioxide, for it is known that carbon dioxide saline baths produce a circumscribed hyperemia, increase the velocity of the circulation, counteract the stasis and empty the aneurysmatically dilated plexus. This means that the blood in the conditioned depots becomes mobilized and that there is an increased discharge into the veins. And it is a fact that during carbon dioxide baths the venous pressure is greater and that the blood supply of the right heart is increased. In a patient who had an extended naevus flammeus, natural, cool, carbon dioxide saline baths effected paling and even a temporary disappearance of the nevus. In a number of patients with acrocyanosis a temporary cure of the local disturbances was obtained. This improvement persisted in some instances for two years. The authors do not mention these therapeutic results of carbon dioxide saline baths in order to recommend them as the only therapeutic measure but hope that they will be the starting point for further studies. In order to find the effect that is actually produced by the carbon dioxide saline baths, the authors made tests to exclude temperature and other factors.

Causes and Symptoms of Hemolysis and Hemoglobinuria—Bingold points out that the causes of hemolysis and of hemoglobinuria have not been completely explained as yet. He detected a new cause for hemolysis, namely, severe contusions of the muscles and the soft parts. The question whether in these cases the hemolysis is due to toxins that are formed in the course of resorption of the destroyed tissues could not be definitely answered. Myogenic influences most likely play a part. Observations on a case of blackwater fever, on horses

with hemoglobinuria and on cases of paralytic hemoglobinuria seem to indicate this. Even in puerperal gas bacillus sepsis, it could be assumed that the lesion of the uterine musculature is the cause of the severe toxic effect on the blood, but absence of hemolysis in the severest muscular destruction, in gas gangrene, militates against this theory. The author points out that hemoglobinuria may lead to an obliteration of the renal filter, to anuria and to complete renal insufficiency. Investigations revealed repeatedly that there are two toxic actions that attack the blood pigments, one separating the hemoglobin from the erythrocytes and the other attacking the blood pigment itself. A methemoglobin formation may set in, but more frequently a hematin formation. The author thinks that many reports about chemical intoxications, which relate only a methemoglobin formation, are erroneous and probably due to the fact that the methemoglobin band and the hematin band are close together. But if the blood or serum is reduced with ammonium sulphide, the characteristic hemochromogen band will appear which shows that it must have been hematin. A pure methemoglobinemia was hardly ever observed, but if hematin is present this is a sure indication of a pathologic process. Thus there are conditions of hemolysis that are accompanied by disintegration of the blood pigments but there are also conditions in which only a hematinemia indicates a pathologic process in the blood. The latter is the case in pernicious anemia in which hematinemia aids in the differentiation from other anemias. If, in case of hemoglobinuria, hemolysis and hematinemia concur the presence of hematin often persists for several days after hemolysis has subsided, which indicates that either the action of the toxin has not yet ceased or that the hematin has not yet been eliminated. This could be proved in two cases of gas bacillus sepsis and in some patients with contusions of the muscles and the soft parts. Hemolysis alone was often observed in hemoglobinuria that developed in intoxication following infusion of heterologous blood. All factors of intoxication (hemolysis, hemoglobinuria, hematuria, methemoglobinemia) were observed in the patients with gas bacillus sepsis, but also in cases of tissue destruction. Perhaps the most significant symptom detected by the author in hemolytic processes with subsequent hemoglobinuria was that the blood pigment which has passed the kidney and is eliminated in the urine has lost its catalase. Since however, catalase provides the protection for the blood pigment against peroxides the unprotected hemoglobin is decomposed into an iron free substrate.

Gastroduodenal Flora in Pernicious Anemia—Otto studied the bacterial flora of specimens of the gastric and duodenal contents of patients with pernicious anemia. He found mainly strains of *Bacillus coli* particularly the serogenic strains, and various types of streptococci. He describes the different strains, their appearance and their behavior toward solutions of dextrose, lactose, mannitol and maltose, also in trypsin bouillon, milk and various culture mediums and their hemolytic or anhemolytic character. By repeating the tests in the course of the treatment, it was determined what influence the therapy exerts on the gastroduodenal flora. The author thinks that pernicious anemia is caused by an insidious, chronic gastroenteritis and its sequels. This gastroenteritis may originate in the stomach and spread to the small intestine, or it may commence in the small intestine and then involve the stomach. If such an inflammation is not stopped, it leads to achylia with atrophy of the gastric mucosa, and all forms of achylia, irrespective of their origin, finally lead to pernicious anemia. The author discusses the action mechanism of the various therapeutic methods recommended for pernicious anemia such as liver, liver preparations, stomach extracts, intestinal extracts, gastric juice and meat, gastric juice and vitamin B and others. He discusses the nervous disturbances and their pathogenesis. He concludes that pernicious anemia is a deficiency disease of bacterial (*coli*) origin with lack of synergism between the gastroduodenal hormone and vitamin B. For the diagnosis it is important that besides the usual symptoms of pernicious anemia a pathologic coliflora be demonstrated in the upper intestinal tract. In the treatment care should be taken that in addition to the hormone-vitamin therapy, a modification of the coliflora be effected, for here lies the danger of relapse.

*Investigations on Sugar Content of Cerebrospinal Fluid W. Mascher —p. 233

Considerations on Curability of Hereditary Psychoses H. von Simon-Himmelstjerna —p. 266

Sugar Content of Cerebrospinal Fluid—Mascher examined 289 punctures made in 133 cases. He says that a constant reduction in the sugar content of the cerebrospinal fluid supports but does not establish the presence of a meningitic process. Increased sugar content does not allow diagnostic conclusion. Increased values are infrequent in encephalitis, are occasionally seen in cases of increased brain pressure, and were found in six out of seven cases of thrombosis and cerebral embolism. There is no 'normal' sugar value in the cerebrospinal fluid while most well persons have a sugar content of from 45 to 75 mg per hundred cubic centimeters, similar values are often found in definitely pathologic cases. The sugar content in the cerebrospinal fluid rises and falls with the blood sugar but lags behind it both in the rising and in the falling curve. The degree of rise or fall of the sugar in the cerebrospinal fluid depends on the duration of the hyperglycemic or hypoglycemic condition respectively. The cause of the lagging is not known. The fall in the sugar values of the cerebrospinal fluid usually depends on glycolysis through bacteria or leukocytes but other still unknown causes must be present in some cases. Cerebrospinal fluids without bacteria and leukocytes show no glycolysis. In purulent meningitis the height of the sugar depends directly on the number of cells. Variations in the sugar content of the cerebrospinal fluid afford no indications as to prognosis.

*Pernicious Anemia Disappearing After Removal of Adenoma of Stomach N. R. Christoffersen —p. 1331

Treatment of Narcotic Intoxications—Of sixty seven cases of intoxication and two of collapse in which massive injections of a 25 per cent solution of pyridine betacarboxylic acid diethylamine were given fifty-six mainly grave intoxications through narcotics were treated intravenously, and thirteen milder cases, intramuscularly. Clemmesen reports six cases in which favorable and lasting effects were obtained from the treatment. Sixteen patients died at once from the poisoning. The treatment was without effect in seven cases. In the majority of the cases the action was favorable but sometimes only temporary. No unfavorable by effects were seen.

Pernicious Anemia Disappearing After Removal of Adenoma of Stomach—In Christoffersen's case the disorder appeared as a pernicious anemia and reacted favorably to liver treatment. Roentgen examination on the occurrence of hematemesis one and a half years after onset of the disorder showed a gastric tumor on removal found to be a broad based tumor with polypous surface and pronounced vascularization. The microscopic structure was that of adenoma. Two years after operation the patient continues well.

PYLORIC OCCLUSION FOLLOWING THE INGESTION OF CORROSIVE LIQUIDS

SAMUEL McLANAHAN, M.D.
BALTIMORE

The drinking of corrosive liquids whether acids or alkalis is not an infrequent occurrence. Usually done accidentally, it is, however, an occasional method of attempted suicide. The results of this violent insult to the walls of the upper digestive tract vary tremendously. Between the minor ulcerations in the mouth and pharynx of the individual who realized his mistake or lost his nerve and the major lesions in the esophagus and stomach are seen many examples of what injury the irritating fluids can inflict. Probably the earliest report of a gastric lesion from such a cause is that of Robert¹ in 1828, whose patient had swallowed sulphuric acid and died after nine weeks. Postmortem examination revealed no pathologic changes in the esophagus, but there were ulcerated areas in the cardiac end of the stomach and the pylorus was markedly contracted. By 1902 Quenu and Petit² were able to collect eighty-four references for their comprehensive article on the subject, these references consisting for the most part of case reports from the early French literature. Additional reports have been published at intervals coming from many parts of the world. In America however, the subject has received comparatively little attention. The report of Boikan and Singer³ indicates, nevertheless, the frequency of the condition, for in less than a year and a half they encountered at the Cook County Hospital five instances of late gastric stenosis following the ingestion of corrosives.

The commercial acids—hydrochloric, sulphuric and nitric—are among the agents most commonly reported as being used. Lye so often swallowed by Negro children, and to lime are less common. The parts of the upper digestive tract show a varying susceptibility to the corrosives and it has further been demonstrated that the various chemicals have a selective action, some differing from others in the regions which they are prone to attack. From an examination of museum specimens and a review of the records, Moynihan⁴ concluded that the parts most affected are the lips and mouth, the pharynx and the first inch or more of the esophagus, the lower end of the esophagus immediately above the cardiac orifice and the pylorus and pyloric

antrum.

So far as the stomach is concerned, the worst injury is inflicted on the pylorus but in severe cases the whole mucous membrane may be affected. Elscher⁵ states that the hydrochloric acid tends to concentrate its effect on the pylorus. A strong solution of sulphuric acid on the other hand, has in several instances caused early death by perforation as soon as it reaches the stomach. Although the lye has been reported as giving gastric lesions and leaving the esophagus unscathed, there seems little question that in the majority of instances it has a distinct predilection for the esophagus and finally produces dense scarring in that region. Many instances of concomitant stenosis of the esophagus and stomach are on record and these have recently been classified into several types by Rochet and Barbier⁶. To conceive of a corrosive liquid traversing the esophagus without apparent injury only to inflict a severe lesion on the stomach, demands a call however slight on the imagination. But such a condition frequently exists as illustrated by the case of Vinson and Harrington⁷ with multiple gastric strictures from formaldehyde. Samaja⁸ in his comprehensive article contributes an explanation on the basis of the tetanic contractions set up in the gastric wall. These serve to concentrate the corrosive liquid at the pylorus and to retain it there. The result is an ulceration of varying depth at that point. Frequently, a more generalized gastritis occurs. The extent of the gastric lesion may well be influenced by the degree of fulness of the stomach, an empty stomach being more apt to suffer a diffuse irritation.⁵ The resulting slough of the mucous membrane continuing for days or weeks accounts for the foul quality of the gastric contents in these patients.

If only the mucosa is ulcerated healing will swiftly follow and the individual will again be well. But this is the exception rather than the rule. Most often the submucosa and the muscular layers are involved also, and these in the pyloric region. The final and characteristic pathologic change occurring weeks or months later is the formation of a dense cicatricial mass at the pylorus. With the development of this mass, obstruction comes *pari passu*. Descriptions of this tumor by various authors are interesting and quite typical. Moynihan has likened the antrum and pylorus to a normal uterus and cervix, "the walls are thick and unyielding the cavity small." He quotes Mr. Keetley as comparing it with 'a small sausage' and in another case stating that there was 'thickening and very tight

structure of the pylorus" Samaja⁹ has termed the swelling "cartilaginous" and Oeding⁹ described it as a "tumefaction" of the thickness of two thumbs." In all these instances, pyloric obstruction was present. Halstead¹⁰ has reported a case in which the lower two thirds of the stomach was "a mass of firm tissue without any cavity," and Nikolas' case¹¹ presented the typical "hour-glass" deformity. Histologically, this mass represents a replacement of the normal layers by fibrous tissue. This fibrous tissue the result of chemical injury, hypertrophies into a thick, dense scar. Quenu¹² described a section in his case as showing the mucosa entirely replaced by a thick layer of fibrous tissue that was intimately mixed with the muscle bundles, especially the internal ones. As the region of the serosa was approached, the musculature became more normal and there was a proportionate reduction in the fibrous tissue.

The early symptoms after taking the poison are necessarily acute. An intense burning, often most marked in the mouth and pharynx is present. A reflex vomiting is shortly set up and may persist for days, and a varying degree of shock is to be observed. Death may ensue in a few hours, as in the case of Chavigny and Laborde,¹³ but not from pyloric obstruction. Blood is often to be found in the vomitus and stools arising from any point along the path of the caustic. For some days food is poorly tolerated and the appetite fails. But after a short period improvement sets in and as in the case of Bruce,¹⁴ the patient may return to his work. Not entirely well, he hopes for daily improvement, which, in milder cases, comes. But in the patient destined for obstruction, symptoms shortly supervene. Quite striking is the observation that the interval between the ingestion of the corrosive substance and the onset of acute obstructive symptoms in the large majority of instances is in the neighborhood of four weeks. This indicates that the mass of scar tissue in

Fig. 1—Appearance interpreted as showing a mild gastritis five days after acid was taken.

the stomach wall previously described must form and enlarge quite rapidly. Some of the early reports are striking exceptions. Obstruction overtook Ortman's

patient¹⁵ five years later, and the patient of Dujardin-Beaumetz¹⁶ succumbed six years after taking the poison.

Loss of appetite and a sense of epigastric fulness usher in his second stage. As the obstruction progresses, intractable vomiting ensues and the patient may not even retain water. When the obstruction has been present for some days the signs of extreme gastrectasis may be elicited. The acid values of the gastric

Fig. 2—Marked narrowing of pyloric antrum twelve days after acid was taken.

contents decline, and the roentgenographic evidence of pyloric obstruction becomes indisputable. If relief of the obstruction is not shortly obtained, extreme emaciation, acidosis and death may follow.

The only effective treatment for such an obstruction is surgical. Historically² there have been four methods of attack used in this condition, namely, dilation of the pylorus, resection of the involved area, pyloroplasty and gastro-enterostomy. Little can be said in favor of the manual dilation of the pylorus (Loreta's¹⁷ method), and although it was tried in England by White and Lane¹⁸ it soon fell into disrepute because of the poor results and has been abandoned in modern times. Resection of the pyloric mass was done early in Germany by Czerny¹⁹ and by Mikulicz²⁰ and has been reported more recently by Routier²¹ and by Putnam²² in this country. Schmieden²³ advises against it because of the difficulty he has experienced in suturing the damaged layers of the stomach wall. In the light of present knowledge such a radical procedure seems unjustifiable unless there is difficulty in differentiating the lesion from a malignant one. Pyloroplasty was likewise practiced in Germany. Mikulicz²⁴ in 1887 performed such an operation on a young woman who

had swallowed a large quantity of vinegar, and Bardeleben²⁵ a few years later did a successful pyloroplasty of the Hemeke-Mikulicz type on a young girl who had had a stenosis of long standing. But Schmieden's objection has held good and no reports of pyloroplasty in recent years have been discovered. This leaves gastro-enterostomy as the most satisfactory method of relieving the obstruction. Credit for the first operation of this type has been given to Monastyrski²⁶. Since that time it has been performed many times and has proved to be the simplest and safest operation. Among many others, the cases of Halstead¹⁰ and Walther²⁷ were treated by gastro-enterostomy.

Frequently however, the patient is too ill for such a major procedure and the minimum is the most that can be done. In such a case, jejunostomy for feeding must be resorted to. This method proved to be a life-saving measure in the first case reported by Kanno and Seian²⁸ and in the case reported by Bruce¹⁴. Noetzel²⁹ has advised it, particularly for hydrochloric acid poisoning. When a complicating obstruction is present in

to a delay on the part of the patient in presenting himself for treatment or to a tardiness on the part of the physician in recognizing the true state of his condition and in giving him prompt surgical attention.

REPORT OF CASE

A. E. G., a man, aged 55, was brought to the accident room of the Union Memorial Hospital, Feb 17, 1932. A few minutes previously he had swallowed, with suicidal intent,

Fig 4—Marked gastric retention six hours after figure 3 was taken

approximately 2 ounces (60 cc) of commercial hydrochloric acid, obtained in a paint shop. He had also been drinking. The acid had nauseated him violently and he was vomiting when he reached the hospital. Occasionally the vomitus was

Fig 3—Almost complete obstruction with similarity to carcinoma twenty three days after acid was taken

the esophagus, jejunostomy feedings must be continued until the esophagus has been sufficiently dilated to admit the necessary nourishment. Gastro-enterostomy may then be performed. The case of Vinson and Hartman³⁰ emphasized the difficulties in recognizing a pyloric obstruction when attention is being directed toward the treatment of dense esophageal strictures.

The prognosis after swallowing caustic liquids is good in the individual who has survived the immediate shock, provided he gets prompt surgical treatment when needed. As in any other benign obstruction relief must be had promptly. The high mortality rate that has existed in past years can be largely attributed either

blood. His mouth and pharynx were quite irritated and he was having cramplike abdominal pains. A large tube was passed and his stomach was lavaged with milk and a solution of sodium bicarbonate. He was then admitted to the hospital under the care of the resident physician, Dr H W Primakoff. On admission the temperature, pulse and respirations were normal. The blood pressure was 116 systolic, 68 diastolic. Apart from the irritation of the mouth and pharynx, the gen-

eral physical examination was negative. The laboratory data revealed that the urine was dark red, was acid in reaction, and showed a specific gravity of 1.012, albumin two plus, and a trace of sugar. There was no acetone, but an occasional granular cast was seen microscopically. The red blood cells numbered 4,550,000 and the white blood cells 9,400, with a normal differential count. The concentration of hemoglobin was 84 per cent (Sahli).

Improvement was steady, although his throat remained quite sore. February 26, he vomited about 250 cc of old blood. There was no further vomiting. As the formation particularly of a stenosing lesion in the esophagus was feared fluoroscopic and roentgen examinations were made. February 22. Reports by Dr C. A. Waters and Dr W. B. Frior were to the effect that (fig 1) there was no esophageal obstruction, the gastric rugae were only moderately hypertrophied and the appearance would indicate a mild gastritis, but there was no evidence of an ulcerated lesion. A week later, February 29, the report

the patient had taken acid. At six hours there was marked gastric retention.

In view of the patient's symptoms, which were gradually becoming aggravated and in view of the startlingly progressive changes noted in the roentgen studies exploration was decided on. He was prepared for operation with a sterilized liquid diet and daily sterile gastric lavages. I performed laparotomy, March 15.

There was found at the pylorus a definite mass measuring approximately 4 cm in diameter, which was causing almost complete obstruction and involved a portion of the antrum. The mass was covered with many small dilated blood vessels and was firm but not fixed. I concluded that the lesion was of an inflammatory nature rather than neoplastic. The regional mesenteric glands were enlarged and one was removed for sectioning. Dr W. C. Merkel, the pathologist, reported it as hyperplastic, inflammatory lymphoid tissue, without evidence of malignancy. A posterior, retrocolic gastro-enterostomy was performed. Care was exercised to suture the transverse mesocolon high on the stomach. The abdomen was closed in layers without drainage. The postoperative course was uneventful except for some delayed healing of the wound. April 11, four weeks after operation fluoroscopic and roentgen examination (fig. 4) disclosed the continued presence of a large filling defect in the pylorus. All of the barium was passing through the gastro-enterostomy opening. At six hours the stomach was still about three-fourths full, indicating that the gastro-enterostomy was not functioning as well as it should. Free and rinses given the following night to determine further the degree of retention were not present in the stomach in the morning. The patient was feeling well and eating abundantly and on April 15 was discharged from the hospital. A month later May 17, roentgen studies were repeated (fig. 5) with the satisfactory observation that all the barium was passing through the gastro-enterostomy opening, the same filling defect was noted. At six hours the stomach was empty and the meal had advanced to the lower descending colon, indicating that the gastro-enterostomy was now functioning perfectly. For eighteen months after discharge he was eating at intervals continuing apparently well and free from symptoms. Late on the night of Oct. 12, 1933, while crossing the street he was run down by a truck and critically injured, sustaining an extensive fracture of the skull with concussion of the brain, a fracture of every rib on the left side and a fracture of the pelvis. He was brought again unconscious to the Union Memorial Hospital where despite every effort at prolonging his life he succumbed two days later, October 15.

Permission was obtained for an autopsy, which was performed shortly after death by Dr W. C. Merkel. Apart from the evidences of the recent acute trauma attention was directed especially to the stomach and its pyloric end (fig. 6). Grossly the stomach was markedly dilated, having almost twice the capacity of the normal stomach. After separation of the adhesions an anastomosis was seen between the greater curvature of the stomach and the proximal portion of the jejunum. The opening through the anastomosis was about 1½ inches in diameter. The pylorus was small, considerably constricted and quite firm to palpation. In order to test patency of the pylorus, the stomach was filled with water. None could be forced through the pyloric ring into the duodenum, indicating complete obliteration. On gross inspection there was no evidence of the presence of ulceration or new growth. The pylorus was markedly atrophic and there was a complete obliteration of the lumen. On microscopic examination of the tissue at the pylorus (fig. 7) the section at the point where the lumen was completely obliterated showed mucosa on both the duodenal and the gastric side which was atrophic. The tissue between these mucosa layers was composed of dense scar and occasional bundles of muscle. The serous surface was normal. The muscularis was considerably distorted by the fibrosis except for the outer circular layer, which was fairly well defined and regular. There was no evidence of any neoplasia.

COMMENT

The case reported is of particular interest for several reasons. In the first place, the roentgenograms illus-

Fig. 6—Specimen removed at autopsy showing pyloric occlusion and the gastrojejunostomy. Relief from symptoms was obtained for eighteen months until death from automobile accident.

was that (fig. 2) there was no evidence of stricture formation in the esophagus. The pyloric antrum was narrowed considerably and presented a type of filling defect which, if the patient had not imbibed hydrochloric acid recently, would suggest a scirrhus carcinoma. Occult blood had been found repeatedly in the stools until March 3, on this and the following day there was no blood. The patient was allowed to go home, much improved, March 5.

At home he experienced more abdominal pain but had no difficulty in swallowing. There was some nausea but no obstructive vomiting. Fluoroscopy was carried out again on March 8 with results similar to those at the previous examination and interpreted as being even more suggestive of a malignant condition. The patient was then readmitted to the hospital. Gastric analysis March 10, revealed no free hydrochloric acid and a total acidity of 10. A roentgenogram (fig. 3) taken the following day showed the filling defect previously noted, still present and somewhat more accentuated. It seemed to be most likely due to a carcinoma in spite of the fact that

trate in a striking fashion the stages in the development of the pyloric occlusion and the relief therefrom as it was actually observed in this patient. The similarity of the roentgen observations to those in carcinoma of the stomach has already been noted by Putnam.²² Even at the operating table he was unable to distinguish the mass from a malignant one and consequently resected it. It appears that only the history of taking poison and the rapid change in the shadow (if it be consecutively followed) and not any inherent quality in the shadow itself will enable the roentgenologist to distinguish the two. No evidence has been found to show that there exists any tendency toward subsequent malignant change in stomachs thus affected. There is emphasized here the value of following carefully, over a period of months, any individual who has swallowed a corrosive substance. Particularly important are the roentgen observations, for by means of them one may anticipate the obstructive symptoms. In the case reported, operation was decided on largely on the basis of accompanying pictures before the man-

ture of the stomach and the pylorus, combined lesions may occur.

3 The typical pathologic change is the formation of a mass of fibrous tissue in the stomach wall at the pylorus, which eventually leads to obstruction.

4 The early symptoms are acute but usually subside. After an interval of four weeks or longer, obstructive symptoms may occur. When pyloric obstruction is diagnosed, surgical treatment should be prompt.

5 Operative methods employed have been dilation of the pylorus, resection, pyloroplasty, gastro-enterostomy or, when required, jejunostomy. Gastro-enterostomy is the method of choice.

6 In the case reported, hydrochloric acid was swallowed, with a resulting pyloric obstruction. Gastro-enterostomy was performed with good result. Particularly interesting were the roentgenograms depicting the development of the lesion and its relief by surgery.

7 The roentgen studies are the most important single aid in determining the nature of the lesion and in anticipating the symptoms.

8 Careful observation of such a patient, and early diagnosis of obstruction, will lead to prompt treatment and a good result.

108 East Thirty-Third Street

Fig 7.—Section from pyloric region showing normal musculature replaced by extensive fibrosis. $\times 30$

started vomiting. The consequence of the careful observation and early diagnosis is that the treatment will be infinitely more satisfactory. The physician in charge can know accurately the patient's status, proper preparation for operation can be carried out and the most appropriate operation can be performed. Truly difficult in diagnosis and treatment is the group of cases in which there exists obstruction simultaneously in the esophagus and in the stomach.

The examination of the postmortem specimen in this case eighteen months after the successful relief of the obstruction by surgery illustrates the fact that the cicatricial mass at the pylorus may decrease markedly in size but that the stenosis shows no evidence of alteration. Indeed the lumen would appear to be more firmly and completely obliterated with the passage of time.

SUMMARY AND CONCLUSIONS

1 The commercial acids and lye are the agents which when swallowed, most commonly cause obstructive lesions of the upper digestive tract.

2 The areas most likely to be affected are the upper and lower portions of the esophagus, the lesser curva-

MALIGNANT MELANOMAS ARISING IN MOLES

REPORT OF FIFTY CASES

THOMAS BUTTERWORTH, MD

READING, PA

AND

JOSEPH V KLAUDER, MD

PHILADELPHIA

The term "melanoma" is given to any abnormal collection of melanin-pigmented cells whether in the skin, in the eye or elsewhere. Malignant melanomas embrace tumors of widely diversified histologic structure.

Malignant melanomas may occur in many situations, the skin, the mucous membrane and the eyes are the most common sites. Rarely the meninges, ovary, epididymis and gallbladder may be involved. As a rule, malignant melanomas arising on the skin originate in pigmented moles or nevi, although there are many authentic cases on record in which melanomas have started at the sites of puncture wounds and in the absence of any apparent congenital abnormality.

Rare origins of malignant melanomas are the blue nevus of Jadassohn and the Mongolian spot. The Mongolian spot is a bluish lesion found in the sacral region. These lesions contain melanin and are devoid of nevus cells. When malignancy develops it is of a sarcomatous nature. Another source of malignant melanoma, nevocarcinoma, is the so-called malignant freckle (lentigo maligna, melanose circumscribed precancerous-Dubreuilh, infective melanotic freckles-Hutchinson). These are pigmented spots appearing usually on the face, mostly in old people.

Clinically, pigmented nevi are classified as hard and soft. Hard nevi are acanthotic and keratotic non-nevus cell tumors, essentially pigmented papillomas, are clinically irregular, warty masses, with a pedicle or a broad

base, or are flat lesions with a rough, papillary surface. They are of a hard consistency and never contain hair. When this type of nevus becomes malignant, it gives rise to squamous epitheliomas.

It is the soft nevi (benign melanomas) that are concerned in the development of malignant melanomas. Histologically, they are characterized by the presence of the "nevus" cells. They are represented clinically as pigmented spots of variable size or as nodular warts, pedunculated, papillary lesions that are soft and often wrinkled, like raisins, or linear or diffuse. They frequently contain hair.

The origin of the "nevus" cell has been the subject of much controversy, which concerns whether this cell is of epithelial origin or stands in genetic relation to the corium.

Masson¹ and Foot² believe that pigmented nevi are nervous, not dermal, tumors, arising from the cells of

histologic structure (1) the melanocarcinoma, (2) the melanosarcoma, (3) the melano-endothelioma and perithelioma. A fourth type is often classified as melanofibrosarcoma. Many tumors fail to come within this classification, presenting in various parts features suggesting each of the several types, and are classified as transitions.

TRANSITION FROM BENIGN TO MALIGNANT MELANOMA

Malignant change in moles may occur at any age of life. While cases in the literature have been reported in patients as young as 6 months⁴ and in others as old as 84 years, still melanoma is essentially a disease of middle life. In our series of fifty cases herein reported, the ages ranged from 17 to 75 years, with an average age of 49 years. This compares with an average of 47 years in 646 cases that we have compiled from the literature, notably including series reported by Boulay,⁵ Gleave,⁶ Cooke,⁷ Amndon,⁸ Coley and Hoguet,⁹ Broders and MacCarty,¹⁰ Hazen,¹¹ and Farrell.¹²

Malignant melanomas occur more frequently in males. In our series there were twenty-nine males and twenty-one females. In 582 cases gathered from the foregoing authors, 52.75 per cent were males and 47.25 per cent were females.

The malignant melanoma is essentially a disease of the white race. Comparatively few cases have been reported in the Negro, and of these the majority have occurred on the unpigmented sole. Mention may be made of the cases reported by Gilchrist,¹³ Wieting and Hamdi,¹⁴ Sutton and Mallia,¹⁵ and Dickson and Jarman.¹⁶

In our series, malignant melanoma occurred in the white race forty-four times and in the colored race six times, one patient being a mulatto. This incidence of melanoma in the Negro may be explained by the prevalence of Negroes treated at the Philadelphia General Hospital.

Malignant melanomas are more likely to develop in moles situated in certain portions of the body. Areas of predilection are the head and lower extremities, particularly the feet. In our fifty cases, the melanomas were distributed as follows: on the face, seven cases; neck, four; trunk, thirteen, of which eight were on the back and shoulders; upper extremities, six; but tocks, thigh and leg, ten; feet, eight; penis, one; and perineum, one. In 598 cases that we analyzed from the literature (Gleave,⁶ Cooke,⁷ Coley and Hoguet,⁹

Fig. 1.—Malignant melanoma in a man aged 50 of two months duration. After one month it started to bleed. The first symptom was elevation of a dark brown lesion which existed for two years. Prior to its increase in size the patient applied daily for two months a tar (?) ointment which burnt the lesion.

the sheath of Schwann. According to these authors, the new growths lie directly in the course of the terminal branches of the cutaneous nerves and are therefore closely related to neurofibromas.

According to Becker,³ the nevus cell question per se is not so important in a consideration of malignant melanoma, since the neoplasms probably do not arise in nevus cell nests but always from melanoblasts at the epidermodermal junction, or from dermal melanoblasts of the blue nevus.

In line with the several theories of the origin of the nevus cell, malignant melanomas arising from moles fall into three general types according to his-

16 Dickson, J. A. and Jarman, T. F. Subungual Melanoma in Negroes. *Ann. Surg.* 95: 470-473 (March) 1932.

Stevenson,¹⁷ Broders and MacCarty,¹⁰ Hazen,¹¹ Dawson,¹⁹ Matras,¹⁸ Horwitz²⁰ and Farrell,¹²) malignant melanomas developed from moles located as follows on the head, 16.5 per cent, neck, 7.7 per cent, trunk, 15.5 per cent, genital and anal regions, 2.7 per cent, and foot, 52.3 per cent.

A comparatively rare localization is in the nail bed or nail fold, so-called melanotic whitlow (Hutchinson). It is characterized by its rapid metastasis, intense pigmentation and breaking down of the regional lymph glands. It resembles the ordinary inflammatory whitlow, excepting that the region of inflammation is surrounded by a very fine black border. A fungating lesion soon develops with loss of the nail and involvement of the regional lymph nodes.

Malignant melanomas may arise in either flat or elevated moles. In our series the moles were recorded in the histories as macular, eleven cases, nodular, six cases, warty, two cases, pedunculated, two cases. In twenty-nine cases the type of mole was not mentioned.

It is generally considered that the black or bluish black mole is dangerous. However, it is evident that melanomas may develop in less deeply pigmented nevi. In twenty-seven of our cases, distinct mention was made of the color of the antecedent mole as follows: black, five cases, black and hairy, one case, brown-black, one case, dark brown, five cases, brown, fourteen cases, flesh colored, one case. In the remaining twenty-three cases the color of the antecedent mole was not recorded.

THE RÔLE OF TRAUMA

The relation of trauma to malignant change in moles has been stressed by many writers. Gleave⁶ reported a history of trauma in four out of twenty-two cases, Amadon,⁸ in eleven out of twenty-seven cases, Coley and Hoguet,⁹ seventeen out of thirty-six cases, of which fourteen were attempts at removal, Stevenson,¹⁷ all of fifteen cases on the feet of Hindus, Hazen,¹¹ six out of seven cases, and Farrell,¹² in thirty-two cases in a total of 159 malignant melanomas arising in moles. Dawson¹⁹ likewise stressed the frequency of slight trauma or mechanical irritation as etiologic factors.

Correlation of trauma with the onset of malignancy has been too remote in many of the reported cases to ascribe to trauma an etiologic role.

In our series of fifty cases there was a history of trauma in thirteen cases. In two of these thirteen cases the history suggested onset of malignancy prior to removal of what was regarded as a benign melanoma. In ten cases, or 20 per cent of the series, it was reasonable to ascribe to trauma an etiologic role in the occurrence of malignant melanoma.

Change in the appearance of the mole, which may be the first symptom of malignancy, frequently motivates its removal. Malignant melanoma appearing subsequently may be a local recurrence rather than a primary malignant growth.

It is not possible to prove that a malignant condition appearing after trauma is not a coincidence. It is reasonable to ascribe, however, an etiologic role to trauma in such reported cases and in our series, as, for example,

a nail in a shoe irritates a mole, the top of a mole is cut off with a razor, attempts are made to strangle a mole with a thread, or an injury causes ulceration that fails to heal. In these cases an isolated or repeated injury was followed in orderly sequence by ulceration and growth of the mole without a long interval of quiescence during which trauma was not applied.

SYMPTOMS OF MALIGNANT MELANOMA

Increase in size is perhaps the first evidence of change from benign to malignant melanoma. Increase in pigmentation usually appears at the same time or soon thereafter. Bleeding is a frequent symptom but may not occur until some months after increase in size and increased pigmentation. Bleeding is accompanied by superficial ulceration, the floor of which is covered with a hemorrhagic crust.

Fig 2.—Benign and malignant melanomas in woman aged 63. For about twenty-five years she had scattered dark brown flat macules (moles) on the back. Five months before the picture was taken the upper right one which the patient said was always blacker than those on the lower part of the back became elevated and more pigmented; bleeding first occurred three weeks before. The adjacent axillary lymph nodes were enlarged. Treatment consisted of wide excision with the endotherm knife and intensive treatment with high voltage to the operative site adjacent regions and right axilla.

Increase in size is manifested as an elevation of the entire patch (fig 1) or one portion of it (fig 2). This elevation soon assumes the appearance of an infiltrated plaque or nodule (fig 3). The formation of a solitary nodule in one portion of the benign lesion, or in its entirety (fig 4), may be the first evidence of increase in size. In this event other nodules soon appear, so that a lesion is formed composed of varying numbers of grouped nodules (fig 5). Frequently satellite nodules develop a short distance from the periphery of the main patch or lesion (fig 6). Excessive enlargement of the primary lesion, invariably presented as a fungating mass, is not the rule. In such an event,

20. Horwitz A. Melanotic Tumors Nonmelanotic Melanomas and Their Relation to the Melano Epitheliomas. *Ann. Surg.* 91: 7 (June) 1930.

metastasis is usually delayed. Conversely, in primary lesions that remain the same size or show slight growth, metastasis usually occurs early. It appears that a malignant growth is expended outward as excessive growth, or inward as metastasis.

Increase of pigmentation is not uniform, portions of the original lesion may vary in color from sepia to slate color or coal black (fig 6). Considerable of the primary lesion may retain its original color (fig 3). Increased pigmentation, presenting a coal black appearance (fig 7), is the rule and is a striking symptom of malignant melanoma.

Satellite spots of pigmentation (fig 7), sepia or coal black, may appear, or they may occur in sprallike fashion. The latter is more commonly seen as a local recurrence after removal of the primary lesion. Occasionally one is able to see fine pigmented radiating

Fig 3.—Malignant melanoma in a man aged 56. It appeared at the site of a pigmented patch that existed for years. Six months before it had reached the stage shown here, at one portion of the patch a firm dark brown nodule appeared which superficially ulcerated and oozed blood.

projections extending into the adjacent normal skin. At times, areas of pigmentation may develop at places remote from the primary lesions. In patients with melanoma, the skin may assume a bronze appearance or a slate blue simulating argyria.

Exceptionally, increase of pigmentation precedes enlargement of the mole. This is more characteristic as a first symptom of malignancy in the so-called malignant freckle. In one of our cases, increase of pigmentation preceded increase in size of the mole by nine months.

Bleeding usually occurs as oozing. Staining of the linen first attracts the patient's attention to this symptom.

Ulceration, other than that accompanying bleeding, has not been conspicuous in our series. Ulceration is

more common after injury, in this event it heals only temporarily.

The history of a pigmented lesion or "birthmark" is not essential. The presence of such a lesion is extremely probable, although many patients state that they were unaware of its presence. When the history of such a lesion is given, its duration varies from birth to different periods thereafter.

The first symptoms may be remote from the primary lesion. Ewing and other writers have emphasized the apparently innocent histologic and clinical characters of certain moles that have given rise to metastasis. The primary lesion may be only slightly pigmented with no increase in size. Indeed enlarged glands may be the first conspicuous symptom, the primary lesion being so small that it is overlooked. In Horwitz's⁹ patient the presenting symptoms were generalized cutaneous nodules and enlarged inguinal nodes that appeared three years after a surgical excision of a small mole on the leg. There was no recurrence at the healed scar. In our series there were a few cases in which the initial symptoms were systemic caused by generalized metastasis, the primary lesion being so insignificant that it was overlooked. In one case the primary lesion was first discovered at postmortem examination.

Melanuria, or the occurrence of melanogen or melanin in the urine, has been regarded as pathognomonic of melanoma. Its occurrence has been reported however, in the absence of malignant melanoma, as in hepatic cirrhosis or subacute hepatitis.

As a summary of early diagnosis it may be stated that increase in size with increase of pigmentation and bleeding is a grave syndrome that justifies clinical diagnosis of malignant melanoma. Late additional evidence is enlargement of the regional lymph nodes. Histologic examination is, of course, conclusive. It should be emphasized that cutting into a suspected malignant melanoma to obtain a section for histologic examination is a dangerous procedure, unless at the same time the entire lesion is destroyed or removed in the manner discussed under treatment. When any pigmented lesion enlarges, becomes inflamed or irritated or changes appearance or, as Hutchinson stated, "becomes aggressive," beginning malignancy should always be considered. With these symptoms however, histologic examination is necessary to make the diagnosis with certitude.

We can appropriately quote the admonition of Hutchinson,²¹ written in 1894:

It is surely quite needless to point out that the only proper treatment of an inflamed or irritated mole is immediate and free excision. On no account should any temporizing measures be permitted. The patient's only chance of safety consists in excision of the whole thickness of skin with a very wide margin. It is much to be desired that all members of the profession should have their minds fully alive to the features presented by these cases and the terrible results of loss of time. It is in the hope of impressing this lesson that I have thought it worth while to publish this portrait.

METASTASIS

The spread of the malignant cells of a melanoma may occur (1) locally by direct extension, (2) by the lymphatics to the regional lymph glands or (3) by invasion of the blood stream with generalization of the disease. The histologic features of the secondary growth vary greatly and they may be nonpigmented.

21 Hutchinson J. Melanosis from Moles. Arch Surg 5: 125, 1894.

nonmelanotic malignant melanomas. Metastatic growths may involve any organ but more especially the liver and lungs.

TREATMENT

Many of the older writers, notably Dupuytren, Velpeau, Cruveilhier and Virchow, taught that treatment of any kind was of little or no value and advised no

operation for removal of the regional lymph nodes. The average interval between the time of excision and recurrence was two years, the longest, ten years, and the shortest, two months.

Our experience has substantiated the observations of Farrell that the expectancy of life is shorter after surgical excision of the lymph nodes than after intensive roentgen therapy.

We believe that the choice of treatment of malignant melanoma is not roentgen or radium therapy or surgery alone but a combination of such treatment. Early diagnosis and treatment are of vital importance. Unfortunately there is considerable delay before the patient reports or is referred for proper treatment. Since microscopic examination of a primary malignant melanoma reveals invasion of the lymphatic structure for about 3 cm. beyond the border of the lesion, excision should include a margin of at least this dimension of apparently normal tissue. We believe excision is best accomplished by means of electrosurgery and should be carried deep enough to include the fascial covering of the muscles.

Following excision, heavily filtered high voltage roentgen therapy should be applied without delay to the operative site as well as to the lymphatics draining this area and the regional lymph nodes. Such treatment should be repeated. The amount of treatment should, of course, be within skin tolerance. With such

Fig. 4—Melanosarcoma in a Negro aged 50. The lesion was light brown and firm to touch. Its duration was two months. The patient was not cognizant of any previous mole.

treatment. It is well known that surgical removal is sometimes followed by rapid generalization and early death. On the other hand, Czerny, Dietrich and Wagner long ago advocated wide extirpation of the melanoma. Later, surgeons advised in addition to such removal a careful dissection of the nearest lymph nodes, whether palpably enlarged or not. More recently, X-rays and radium have been employed. It should be noted that at times rapid generalization of the melanoma occurs after roentgen therapy, also the initial appearance of melanin in the urine.

Operative removal of the malignant melanoma is frequently followed by recurrence at the site of excision. Amadon⁸ reported local recurrence in 33 1/3 per cent of twenty-seven malignant melanomas arising in moles. Farrell¹² reported local recurrence in 30 per cent of 265 cases of cutaneous melanomas. In these cases the average interval between the time of excision and the appearance of new lesions in and around the scar was two years, the longest interval was fifteen years, the shortest, three weeks. In our series there was a local recurrence in 20 per cent of the forty cases we were able to trace. In each instance the primary lesion had been removed by means of the scalpel.

It is important to note that in Farrell's series there was local recurrence in the regional lymph nodes in 18 per cent of the cases in which the patient had an

Fig. 5—Malignant melanoma in a woman aged 42. It first appeared as a black spot eighteen months before the pigmented nodules shown here which disappeared following the application of radium. Cutaneous metastasis without local recurrence occurred eighteen months after radium treatment. The patient died three years after the radium treatment and fifty-five months after the first symptoms. (Courtesy of Dr. Bernard Widmann.)

roentgen therapy, whether the regional lymph nodes are enlarged or not, we are not convinced of the wisdom of surgically removing them. If such an operation is performed we believe it should be done only after preliminary roentgen treatment.

In malignant melanoma situated on a portion of the body that can be amputated and if seen early, certainly before enlargement of the regional lymph nodes, amputation should be given serious consideration. If amputation is performed, roentgen therapy should be applied to the areas and in the manner stated in the foregoing.

In our series we were able to trace forty cases. Of these, death occurred in twenty-six in an average of two years and seven months after the first appearance of malignancy in the mole. In our two most rapidly progressive cases, death occurred in seven and nine months, respectively. Fourteen patients are still living, in eight of whom the duration of malignancy has been less than three years. In the remaining six patients the duration has been more than three years ranging from 41 months to 101 months. The eight patients still living less than three years will not be considered in the analysis of the result of treatment of the remaining thirty-two patients.

Fig 6—Malignant melanoma in a woman aged 57, as it appeared two years after the first symptoms of malignancy which were elevation of the patch, increase of pigmentation, appearance of nodules and bleeding. The melanoma was deeply pigmented and elevated. Its surface was studded with black nodules, some of which extended beyond the margins of the main patch. It appeared at the site of a dark brown patch which existed at birth. Generalized metastasis and death occurred thirty-two months after the first symptom of malignancy.

Excision of the inguinal lymph nodes in one case and the application of radium to the original growth in another case were shortly followed by widespread metastasis. In two cases in which excision of the melanoma was done with roentgen therapy to the site of excision and over the regional glands such roentgen treatment was delayed for a number of months after excision.

PROGNOSIS

Generalized metastasis is usually stated to occur in an average of three years from the first symptoms of malignancy in the primary growth. In Dawson's series it took place earlier than this in most cases. Our records show that generalized metastasis occurred in an average of twenty-five months. However, there is great variation in the rapidity of development of visceral metastasis. In two of our cases there was gen-

eral metastasis after four months, and in a third case after nine months. On the other hand, some patients show marked resistance to the extension of the disease, as in two fatal cases in which generalization did not occur until after fifty-four months.

The duration of life after the onset of a malignant condition is variable. In Hazen's patient, generalized metastasis and death took place within six months of onset of the malignant condition. A malignant growth in this case followed injury to a mole, whereas in Watson's patient generalized metastasis and death occurred twelve years after onset of the malignant condition.

The majority of patients succumb within three years after the onset of the malignant condition, the minority, within three to five years. Relatively few live longer than five years. Of twenty patients with malignant cutaneous melanoma, only two were living five and seven years, respectively, after the onset of the malignant condition. In one patient, generalized metastasis and death occurred ten years after onset. Dittich's²² series embraced thirty-nine patients, of whom 92 per cent died within five years. One patient was still living nine years after the onset of the malignant condition. Coley and Hogue⁹ reported an average duration of life in twenty-eight patients to be two years and eight months, with extremes of nine months and six years.

Analysis of Thirty-Two Cases of Malignant Melanoma

No. of Cases	Survived 3 Years	Comment
10	7	Excision of melanoma & rays to site of excision & regional glands
6	3	Excision of melanoma alone
3	0	Excision of melanoma and lymph nodes
1	0	Excision of melanoma and lymph nodes with roentgen follow up
1	0	Excision of melanoma & radium to nodes
2	1	Radium to melanoma alone
1	0	Rays to melanoma alone
8	1	No treatment at all

It becomes apparent that the prognosis of malignant melanoma is grave. Do all patients with malignant melanoma eventually succumb as a result of their disease? One finds in the literature reports of patients who are living and are without evidence of metastasis at variable periods after removal of the malignant melanoma. Such reports have a limited interpretation as to cure, since metastasis to the regional lymph nodes occurred eight years (Müller's²³ case) and twenty years (Eve's²⁴ case) after the onset of the malignant condition, and general metastasis and death after twelve years (Watson's²⁵ case). This remarkable latency in the development of visceral metastasis is more characteristic of intra-ocular melanoma. The prognosis of intra-ocular melanoma is better than that of malignant cutaneous melanoma.

The nearest approach to cures that we have been able to find in the literature embraces the following reports. The patient whose case was reported by Chauvin²⁶ and later by Mourgue-Molines²⁷ was 28 years of age when

a malignant melanoma on the face was first excised. During the subsequent twenty-six years, operations were performed six times for local recurrences. Metastasis did not occur. Cumming²⁸ reported the case of a man, aged 66, who had had a malignant melanoma removed from the heel. Despite local recurrence there was no metastasis after fourteen years.

In view of the long period of latency in the development of visceral metastasis, it appears that criterion of cure necessitates negative postmortem and histologic examination for evidence of malignancy. We are unacquainted with any such reports. The following case record in our series approaches fulfillment of this criterion.

A man, aged 72, had had a malignant melanoma on the lobe of the ear, which had been present for thirty-seven months before it was destroyed by electrodesiccation. Histologic examination confirmed the diagnosis. Following its destruction, intensive roentgen therapy was repeatedly applied to the side of the face and neck. Seven months after such treatment,

the patient died of cardiorenal disease. Postmortem examination showed no gross or histologic evidence of metastasis. There was no local recurrence. The regional lymph nodes were not enlarged. These nodes, however, were not removed for histologic examination.

Fig 7—Malignant melanoma appearing at site of brown patch present since birth, showing coal black lesion, one portion of which is elevated, superficially ulcerated and crusted with satellite pigmented papules. It became darker one year before increased in size three months before and was first noticed to bleed about one month before it reached the stage shown here. Death occurred nineteen months after the onset of the first symptom.

moles at sites subjected to continuous irritation, others advise removal of all pigmented cutaneous lesions in order to prevent malignant melanoma. In discussion, the following considerations are pertinent. Pigmented lesions on the skin of divers appearance are extremely common, whereas the incidence of malignant melanomas is uncommon. In Folger's³⁰ study of 2,274 malignant tumors in 18,113 cadavers, twenty, or 0.89 per cent, were melanotic. Not all pigmented lesions are potentially malignant melanomas. In a histologic study by

Klauder and Saleeby of 100 pigmented lesions removed consecutively from 100 patients, 60 per cent were nevus cell tumors (soft moles).

The routine removal of all pigmented lesions in order to prevent malignant melanoma is not practical. However, it appears advisable to remove such lesions when situated on the head and feet, the most frequent sites of malignant melanomas, and to remove pigmented lesions subjected to irritation incident to such objects as razors, corsets, braces or trusses or from scratching.

The color of a mole is not a criterion of potential malignant melanoma, since unpigmented moles may become malignant melanomas, although the occurrence is exceptional.

"Thorough destruction, including healthy tissue surrounding the lesion and beneath it, by means of the electrocautery, electrodesiccation or surgical excision, affords the safest means of removing pigmented nevi. The nevus should be entirely destroyed in one operation. To treat these lesions by painting with acids, by applying carbon dioxide snow, by electrolysis, strangulation by tying a string around a pedunculated lesion, or any treatment given at short intervals, are dangerous procedures which constitute irritation and afford opportunity for malignant change. In propaganda for the control of cancer, this principle cannot too strongly be emphasized."³¹

FATALITIES IN EXFOLIATIVE DERMATITIS

ALLAN K POOLE, M.D.

AND

ROLAND T WEHGER, M.D.
NEW HAVEN, CONN.

This paper is an attempt to explain the actual mechanism of death in cases of exfoliative dermatitis. The few references in the literature explain the death as due either to septicemia or to bronchopneumonia. Although clinically the changes are compatible with a diagnosis of bronchopneumonia, it was felt that this might not be the case. This idea was strengthened in 1931, when one of us¹ reported a fatality resulting from phenobarbital. The autopsy in this case showed that the exfoliative process involved the trachea, the bronchi, the alveoli and, to a less extent, the urinary tract. Although clinically the patient presented a fairly typical picture of bronchopneumonia, the autopsy failed completely to show pneumonia. It seems obvious from the autopsy that death was actually due, in part at least, to suffocation or to anoxemia. In view of this, a survey of the literature and a review of our own autopsies have been undertaken in an attempt to study the problem further. Our chief interest lay in the cases due to arsenic but we have not limited the study to this particular group.

LITERATURE

The literature on drug idiosyncrasies is quite extensive and we prefer to limit the references to those dealing more or less specifically with exfoliative der-

matitis Klauder² in 1924 summarized the various types of skin reactions following the use of intravenous arsenicals. The incidence of toxic reactions to the various arsenicals has been reported by the British Research Council Phelps³ and Cole.⁴ Toxic manifestations from the barbituric acid derivatives have been recorded by Menninger,⁵ Poole¹ and Lundy.⁶

A survey of the literature reveals the fact that the number of fatal cases reported is not large. It is reasonable to suppose, however, that there are many other cases that have not been reported. The number of cases that have come to autopsy and have been fully reported are extremely few. Only seventeen have been found. These are summarized in table I.

At autopsy case 1 (table I) showed bronchopneumonia in the right lower lobe with some pus in the bronchioles. Elsewhere the lungs were edematous. The kidneys were large and pale, the liver was pale and fatty. In case 2 (table I) the conditions found at autopsy were edema of the lungs without consolidation, a large spleen and a large pale liver. In case 3 (table I) the lungs showed several infarcts surrounded by an area of bronchopneumonia. The spleen was "inflamed" over these areas and elsewhere showed subpleural petechiae. There were numerous petechiae in the gastro-intestinal tract. Unfortunately there is no detailed description of the histologic examination.

TABLE I—Autopsies Reported in Literature

Case	Clinical Diagnosis	Lungs	Kidneys	Liver	Gastro-Intestinal Tract	Author
1	Arsenical dermatitis	Bronchopneumonia	Large and pale	Fatty degeneration		French ⁸
2	Arsenical dermatitis	Edema		Large, pale		French ⁸

French⁸ reported three cases showing extensive dermatitis in which the exfoliative process also involved the mucous membranes of the mouth and throat. The terminal event in each case was thought to be broncho-

Williams and Pfluke⁹ reported a case (4, table I) in which death occurred one week after the fifth dose of sulpharsphenamine. A dermatitis and jaundice developed in this case. The pulmonary signs were not described. Autopsy revealed markedly congested edematous and emphysematous lungs. The spleen and liver showed chronic passive congestion and there was a periportal round cell infiltration in the liver.

Robinson¹⁰ reported thirty-three cases of arsenical dermatitis with eight deaths. No autopsies were reported.

Stokes and Cathcart¹¹ reported a fatality (case 5, table 1) apparently due to bronchopneumonia or cardiac failure. Autopsy failed to reveal any pulmonary conditions. The colon and rectum showed extensive ulceration. In the case reported by Stumpke¹² (case 6, table 1) the patient received neoarsphenamine and mercuric salicylate simultaneously. At the end of the course of treatment, a rash appeared, then stomatitis, diarrhea and death. Autopsy showed mitral stenosis

Fig 1 (case 1)—Desquamation of alveolar lining epithelium and organizing focal pneumonia reduced from a photomicrograph with a magnification of 125 diameters

and insufficiency, hemorrhagic enteritis, pyelitis, glomerular nephritis, cystitis and a fatty liver.

In Riehl's¹³ patient (case 7, table 1) a dermatitis developed two weeks after the completion of a course of treatment consisting of a total of 27 Gm of neoarsphenamine and 10 Gm of a bismuth compound. With the dermatitis, the mucous membranes of the mouth and conjunctivae were involved, and multiple subcutaneous abscesses developed. Death occurred six weeks after the onset. The autopsy diagnosis was bronchopneumonia of the right lower lobe, fatty degeneration of the liver, degeneration of the kidney parenchyma, and degeneration of the cord.

Moore and Keidel¹⁴ reported three cases with autopsy (cases 8, 9 and 10 table 1). One of these showed aplastic bone marrow and in all the lungs showed areas of bacterial invasion without cellular exudate. In all three cases there were innumerable hemorrhages in all the organs most marked in the lungs, gastro-intestinal tract and kidneys. There was also desquamation of the mucous membranes of the bronchial tree.

A case of dermatitis complicated by abscesses (case 11 table 1) was reported by Heyn¹⁵. The autopsy revealed bronchopneumonia, pleuritis, peritonitis and mediastinitis.

Moore and Foley¹⁶ reported in detail four cases with one death (case 12, table 1). In the fatal case the

patient received seven intravenous treatments with arsphenamine and three intrathecal injections of serum. After each intravenous treatment there was malaise and usually a temperature of from 101 to 103 F. The day after the seventh treatment, the temperature rose to 103.8, chills occurred and an itching, maculopapular rash was noted. Four days later the rash had become hemorrhagic and edema of the lower extremities and genitalia appeared. The next day the liver was palpable, and the edema and desquamation were quite marked. Polyuria was present for the first ten days, then decreased to a complete anuria. A few white blood cells were present in the urine but no red cells. Kidney function tests showed a steadily increasing impairment. Death occurred on the sixteenth day. At autopsy the lungs were voluminous and showed areas of hemorrhage and granular spots. The kidneys were large and showed scattered hemorrhages on the surface and engorgement along the pyramids. In the stomach there were numerous small areas that were denuded. Microscopically, the lungs showed edema, the alveoli contained frothy, pink-staining material, desquamated epithelial cells, a varying amount of red blood cells and an occasional white blood cell. In many areas, the alveolar walls were destroyed. There was marked congestion of the kidneys, with multiple small hemorrhages. Tubular desquamation was marked and the lumens of the tubules were filled with a granular precipitate.

Phelps and Washburn¹⁷ reported four cases, only one of which (case 13, table 1) came to autopsy. On the nineteenth day, multiple subcutaneous abscesses developed. Three days later chills, a cough and signs of bronchopneumonia were noted. Autopsy showed multiple lung abscesses, but the kidneys were normal.

Fig 2 (case 1)—Desquamation of alveolar lining epithelium reduced from a photomicrograph with a magnification of 125 diameters

The next four are fatal cases of exfoliative dermatitis but were not due to arsenic. The first three were reported by Bowen¹⁷. His first patient (14, table 1) had had generalized pruritus for nine months and desquamation for two months. The physical changes were those of exfoliative dermatitis with involvement of the mucous membranes of the mouth. The condition remained stationary for three months, at which

time the liver and spleen became palpable, bloody sputum was noted, there was bleeding from the mucous membranes, and purpuric spots appeared on the lower extremities. No blood was found in the urine. Death occurred one month later. At autopsy the bronchi were found to be filled with yellow pus and there was marked injection of the mucosa. The liver and spleen were enlarged and there was myocardial degeneration.

Fig. 3 (case 2)—Congestion and desquamation in the bronchiole reduced from a photomicrograph with a magnification of 75 diameters.

Bowen's next case (15, table 1) was thought to be due to mercury. The course was steadily downhill and was characterized by a severe anemia and a streptococcal infection. The autopsy revealed only hyperplasia of the spleen and evidence of a streptococcal infection.

His third case (16, table 1) had a scaling dermatitis which had been present fifteen months and appeared to be improving until pneumonia developed and the patient died within forty-eight hours. The right lung showed indurated red areas, which faded into the surrounding leathery lung tissue. The bronchi were reddened and exuded a red mucopurulent material. Microscopically these areas were called bronchopneumonia. There was also some fatty degeneration of the liver.

The last case (17, table 1) was that of a Negro reported by Ludy and his associates,¹⁸ and was apparently due to the use of laundry soap. On the tenth day there was a generalized exfoliative dermatitis with marked involvement of the oral mucous membranes. On the thirteenth day there was marked anasarca, followed the next day by pulmonary edema and anuria. Death occurred on the fifteenth day. Autopsy revealed a marked subcutaneous edema, bilateral hydrothorax, ascites, and edema of all the viscera. The trachea and bronchi were injected. The mucosa of the gastrointestinal tract was blotchy. There were petechiae in the kidney pelvis. The medullary portion of the suprarenals was thinner than usual. Examination microscopically showed the alveoli of the lungs to be filled with a basophilic staining coagulum containing many red blood cells, lymphocytes and polymorphonuclear cells. There was also peribronchial infiltration with lymphocytes and leukocytes, and the epithelium was stripped from the walls of the bronchioles and was

lying free in the lumens. Acute diffuse nephritis, lymphoid hyperplasia, hyperemia of the small intestine, parenchymatous degeneration of the liver and spleen, and "cell exhaustion" of the suprarenals were also noted.

SUMMARY OF CASES IN LITERATURE

Although deaths from exfoliative dermatitis are not infrequent, it was difficult to find reports of cases that had come to autopsy. There are many cases, both fatal and nonfatal, which are described as showing bronchopneumonia and often anuria occurring at the same time that the skin lesions were most severe. Only seventeen reports with autopsies were found and in many of these the reports were meager, so that a critical analysis is impossible. There are, however, a few features that are suggestive. Out of seventeen cases, thirteen of which were due to arsenic, bronchopneumonia was apparently present in ten. At autopsy, however, fourteen were found to show pulmonary pathologic changes of some type. Although the description is meager in many cases in five of them it is definitely stated that desquamation of the epithelium of the air passages was present. Edema was noted in two of these cases, two showed abscesses, and one is reported as showing infarcts and pneumonia. The remaining nine of the fourteen cases showed at autopsy what might be called bronchopneumonia. However it is not possible that a restudy of these preparations might result in a revision of the diagnoses. Without this it is apparent that at least five of the fourteen cases in which pulmonary pathologic changes were present showed lesions that were either directly or indirectly due to damage of the epithelial layer of the respiratory tract.

Although nephritis was a clinical diagnosis in only two cases renal lesions were found in eight. The kidney lesions noted are acute nephritis and glomerulo-

Fig. 4 (case 2)—Pelvis of kidney showing loss of epithelium and congestion of mucosa reduced from a photomicrograph with a magnification of 60 diameters.

nephritis, three cases hemorrhages present in the pelvic mucosa, three cases, degeneration, one case, cloudy swelling, one case.

REPORT OF CASES

A review of our own cases of exfoliative dermatitis reveals four fatal cases that have come to autopsy. We believe that the observations warrant a detailed report

18 Ludy, J. B., Cogswell, L., and Hunt, E. L. Dermatitis Exfoliativa. Report of a Fatal Case. *J. Cutan. Dis.* 37: 524 (Aug.) 1919.

CASE 1—History—F J, a white woman, aged 47, admitted to the dispensary, Oct 2, 1925, was found to have mild diabetes, syphilis of the central nervous system, and a scar of a healed gumma on the roof of the mouth, with a perforation through to the antrum. Treatment consisted of three doses of 0.4 Gm of sulpharsphenamine intramuscularly, the last being given on November 2. November 14, a rash appeared and on November 19 she returned to the dispensary with a severe exfoliative dermatitis. She was immediately admitted to the ward for treatment. Sodium thiosulphate was given intravenously, and an attempt was made to eradicate the severe focal infection in the antrum. Both of these procedures failed to yield results. The white blood cell count on admission was 13,400, and there was marked eosinophilia, 31 per cent. November 24, rales were noted at the bases of both lungs and there was slight suppression of breath sounds but no percussion note changes were present. A friction rub was audible in the left axilla. By December 1 there was marked involvement of all the visible mucous membranes, and the nares became plugged. The dry hacking cough and the lung signs persisted, but a roentgenogram of the chest, December 9 did not reveal pneumonia. The temperature continued to fluctuate between 101 and 102 F. December 15, it was noted that the output of urine was decreasing. There was edema of the lower extremities, erythrocytes and casts were present in the urine, and the nonprotein nitrogen of the blood was 42 mg. From this point the course was slowly downhill. Jan 10 1926 the temperature began to rise, remaining at about 105 for the last five days. Death occurred, January 21.

Autopsy—There was marked desquamation of the skin. Mucous membranes were pale and edematous. The lungs were voluminous. The pleura was thickened and adherent over the apex and lateral surface of the left upper lobe. Beginning in the trachea and increasing in the bronchial tree the mucosa was swollen, dark red and covered with mucopurulent material. This was also true of the smaller bronchioles and, as the lung was cut, purulent material exuded from them. Throughout the lungs but more marked posteriorly, were dense nodules, from 1 to 4 cm in diameter. When cut these nodules appeared as zones of grayish white, friable, granular tissue, surrounded by apparently normal lung tissue.

In every portion of the lung studied microscopically there was evidence of an exudative and reparative process. There was an acute exudate, an early organizing process, some resolution, and everywhere regeneration of the alveolar epithelium. The exudate consisted of loose fibrin in small amounts, polymorphonuclear leukocytes, and large mononuclear cells filled with nuclei or red blood cells. The bronchi and bronchioles were filled with polymorphonuclear leukocytes and desquamated epithelium. The regenerated epithelium was of the low cuboidal type and was detached from the wall.

The liver was large and light brown, with an indistinct lobulation. Diffusely scattered throughout the liver were small dark red islands, 1 mm in diameter. The tissue was friable and had a greasy appearance.

Vacuolization was so extensive that the tissue was scarcely recognizable microscopically. Each liver cell contained a large vacuole pressing the nucleus to the periphery and leaving very little cytoplasm. About many of the central veins some normal liver cells were found. The sinusoids were congested.

The capsules of the kidneys stripped readily leaving a congested cortical surface in which the cortical vessels were distinct.

Fresh blood cells formed casts in many of the tubules and filled many distended glomerular spaces. All the glomerular vessels were congested. Cloudy swelling of the convoluted tubules was noted.

CASE 2—History—S T, a white woman, aged 41, admitted to the hospital Feb 14 1927, complained of a severe chronic nephritis and hypertension. Because of insomnia she was given phenobarbital, 1½ grains (0.01 Gm.) February 15 17 and 19. February 24 an itching and generalized maculopapular eruption developed, covering the whole body. That evening the rash became more prominent, papular lesions appeared on the hard palate and the temperature rose to 102.6. The next day there was a marked conjunctivitis, and the

entire buccal mucosa was red and studded with petechiae. By February 28 the rash had become copper colored and appeared to be urticarial in type, and desquamation began. The throat became so sore that deglutition was impossible. March 1, it was noted that the papules on the hard palate were ulcerated. The next day, because of a stiff neck and a bilateral Kernig sign, a lumbar puncture was done. Forty-one cells were found, all lymphocytes. March 3, the temperature rose to 104 and the pulse to 170. Coarse rales were heard over the entire chest, the patient became comatose and died that afternoon.

Autopsy—There was an extensive desquamating rash of the entire body, most marked on the forearms and back and involving the mucous membranes.

Posteriorly, the lungs were red and heavy. When they were cut, edema and congestion were seen in these areas. The bronchi were congested and the mucosal surfaces were granular.

The greatest alteration was in the bronchi. In many, the epithelium was desquamated. The capillaries of the mucosa were engorged, and there was edema and infiltration of leukocytes, mostly of the mononuclear variety. In the alveoli there was edema, emphysema and congestion.

The liver was brownish red, the capsule was smooth and the lobular architecture was accentuated. The histologic sections appeared normal.

Fig 5 (case 3)—Desquamated epithelium completely occluding the air passage reduced from a photomicrograph with a magnification of 100 diameters.

Both kidneys were small and scarred, and the capsule was thick and adherent. The cortex and medulla were indistinguishable and were a dark red gray.

Microscopically, there was a diffuse increase in connective tissue. There was thickening of both media and intima of the arteries. The capillaries were congested, and practically all the glomeruli were altered in some way—hyalinization, fibrosis or necrosis. In some glomeruli the epithelium had regenerated between the adhesions. Some of the tubules had blood in them, others had epithelial cell casts. In numerous areas the epithelium of the tubules was lifted from the basement membrane and was lying detached in the lumens. The renal pelvis showed great congestion and edema, with desquamation of the lining epithelium and organization along the surface. A similar condition was found in the ureters.

CASE 3—History—J F, a white man, aged 42, admitted to the dispensary March 17 1928 was found to have a gumma of the hip and aortic insufficiency. After a preparatory period of mercury inunctions and potassium iodide by mouth he was started on small doses of neoarsphenamine 0.45 Gm at weekly intervals receiving the eighth treatment on June 7. June 11 he noticed an extensive itching rash over the body. Two days later edema of the ankles developed. He returned to the dispensary on this date and was immediately admitted to the hospital. At this time June 13, there was an extensive

erythematous rash and edema of the skin over the entire body. Below the knees there were numerous purpuric spots. The liver was enlarged 2 cm below the right costal margin and there was jaundice of the sclerae. The white blood cells numbered 11,500, with 66 per cent polymorphonuclear neutrophils and 1 per cent eosinophils. Treatment with thiosinamine (intravenously) was begun and there appeared to be some improvement. By June 24 there was marked exfoliation and it was evident that thiosinamine was having no effect. The temperature rose to 103 on June 26 and remained elevated.

Fig. 6 (case 4)—Desquamation of epithelium of bronchiole reduced from a photomicrograph with a magnification of 100 diameters.

Although there were no signs of renal impairment the blood pressure rose from 120 systolic 40 diastolic to 190 systolic 40 diastolic. July 4 there was marked dyspnea, orthopnea and cyanosis, and the patient died a few hours later.

Autopsy.—There was a generalized exfoliative dermatitis, the exfoliative process involving also the mucous membranes of the eyes and the upper air passages.

In the lungs there was approximately 600 cc of straw colored fluid in each pleural cavity and there were numerous easily broken pleural adhesions. The lungs were crepitant. On section a red tinged fluid exuded from the alveoli and from some of the bronchi. A few zones seemed to be elevated above the rest of the tissue; these were somewhat lighter in color than the rest of the surface. The mucosa of the bronchioles in these places was reddened and contained thick mucus.

There was congestion of the vessels microscopically, particularly in the left lung. In both lungs, but more marked in the left, there was an increase in the size of some alveoli and a decrease of others in the same field. The alveoli contained a varying amount of exudate consisting of a few polymorphonuclear leukocytes, large mononuclear cells with a small amount of cytoplasm and larger mononuclear cells of the "heart failure" type. The epithelium of the bronchioles was sloughed off practically everywhere, lying in the lumens along with a polymorphonuclear and fibrinous exudate. Polymorphonuclear and mononuclear cells were seen in the walls of the bronchioles and some fibroblastic proliferation was present.

The heart and aorta showed definite changes due to syphilis and there was also a healed mitral lesion.

The liver was enlarged, weighing 2200 Gm and extending 3 cm below the costal margin. The lobulations appeared light in color.

Microscopically the cells had a swollen cloudy appearance, and the central sinusoids were engorged with blood. The portal spaces showed small round cell infiltration.

There was no evidence of destruction of the renal epithelium.

There were areas of congestion in the mucosa and some submucosal hemorrhages in the large intestine.

It was seen that the epithelium was almost entirely gone except for the glands of the mucosa. All layers showed congestion of the vessels, with some free hemorrhage.

There was generalized desquamation of the skin. There were many areas in which the desquamation had left raw surfaces, and these were covered with crusts.

The superficial keratinized layers were absent. The blood vessels were dilated and engorged with blood. Clumps of small round cells were seen below the epithelium by microscopic examination.

CASE 4—History.—B. G., a white girl infant, aged 4 weeks, was admitted to the hospital, Nov. 12, 1923, because of exfoliative dermatitis which appeared five days before admission. No cause for the dermatitis was determined. Because of its severity, satisfactory examination was impossible. The conjunctivae were involved in the process, and the mucous membranes of the mouth were covered with lesions of thrush. The condition became rapidly worse, septicemia (hemolytic streptococcus), developed, and the child died, November 15.

Autopsy.—Except for a few small areas on the chest and back the entire superficial layer of epidermis was denuded, leaving a dry smooth indurated surface. In a few places the surface was moist and finely papular. The conjunctivae were injected. The mouth and pharynx were covered with a mucosanguinous exudate.

The keratinized layer was missing. No cellular infiltrations were seen with the microscope.

The lungs were pink and crepitant except for a few small depressed reddish areas. The bronchi were slightly reddened.

The preparations showed many of the alveoli to be atelectatic, whole lobules being collapsed in some areas. The alveoli were filled with desquamated epithelium and the walls were thickened. The bronchi also contained desquamated epithelium. The process was quite marked in the trachea. The mucosa of the larynx below the vocal cords was missing.

No significant conditions were found in the other viscera.

COMMENT

Although the etiologic agent in these cases varied in that two cases were due to arsenic, one to phenobarbital and one to an unknown agent, there are a number of points of similarity. The literature, for the most part, states that death in such cases is due to bronchopneumonia. In our own series this was the

Fig. 7 (case 4)—Desquamated epithelium lying free in the lumen reduced from a photomicrograph with a magnification of 100 diameters.

diagnosis at death in all but the last case. The physical manifestations were essentially those of bronchopneumonia. The changes found at autopsy in our cases were not those of bronchopneumonia but merely the extension of the exfoliative process into the lungs. A survey of the sections immediately suggests that death in these four cases was in part suffocative, owing to the mechanical blocking of the air passage and not to a pulmonary infection.

From a survey of the autopsy reports found in the literature, it is striking that fourteen showed definite pulmonary pathologic changes. In five of these it was definitely noted that desquamation of the epithelium of the tracheobronchial wall had occurred. It seems possible that the fundamental process in all of them was the same as that in the cases we are reporting. Of course, a secondary infection may be superimposed on the underlying process, although it was found in only one of our own cases. It seems possible that some of the cases reported in the literature as "arsenical stomatitis" may be merely an exfoliative process limited to the air passages.

A second point of similarity is the finding of a similar exfoliative process in the urinary tract. The lesions

TABLE 2—Observations Made at Autopsy of Authors' Cases

Case	Clinical Diagnosis	Lungs	Kidneys	Liver	Gastro Intestinal Tract
1	Arsenical dermatitis diabetes tabes dorsalis broncho pneumonia	Desquamation inflammatory reaction	Congestion	Degeneration	
2	Phenobarbital dermatitis chronic nephritis broncho pneumonia	Desquamation edema	Desquamation in tubules and pelvis		
3	Arsenical dermatitis tertiary syphilis toxic hepatitis	Desquamation		Congestion	Multiple hemorrhages
4	Exfoliative dermatitis etiology unknown	Desquamation			

here were less extensive than in the lungs, involving only the renal pelvis in most cases. Seven cases reported in the literature noted renal involvement of some type.

SUMMARY

1 In seventeen cases of exfoliative dermatitis with observations at autopsy which have been collected from the literature, fourteen showed pulmonary pathologic changes.

2 All four of our cases showed epithelial exfoliation of the respiratory tract and no evidence of pneumonia.

3 A similar process may occur in the kidneys.

4 It seems that an important contributing cause of death in cases of exfoliative dermatitis is not pneumonia but obstruction of the air passages, due to exfoliation of the epithelium.

Elements in Animal Tissues—The following elements are present in the ash of animal tissues: iron, sodium, potassium, magnesium, calcium, phosphorus, sulphur, chlorine, iodine, fluorine, lithium, barium, manganese, aluminum, copper and silicon. Some of these are needed in such small quantities that a sufficient supply is assured by almost any diet; others are needed in such large amounts that the diet often fails to furnish a sufficiency, especially in the case with iron, calcium and phosphorus. Iron is needed for the hemoglobin of the red blood corpuscles. It is found in red, yellow and green foods—that is in red meats, fresh lean meat, especially in liver, which is valuable, perhaps because of the copper as well as the iron content, in yolk of egg and carrots, and in vegetables and fruits and the hull of cereal grains. Food materials with little chlorophyll have little iron content. Milk has a low iron content but in readily assimilable form. Fats, sugars and starches contain little iron.—Nixon J. A. *Food Values and Their Practical Application in Dietetics*, Brit. M. J. 11 (Jan. 6) 1934.

TREATMENT OF DECUBITUS WITH TANNIC ACID

EARL O. LATIMER, M.D.

CHICAGO

Decubitus, or pressure sore, is the result of local impaired nutrition, frequently in a person whose tissues have a lowered resistance because of age, disease, injury or nerve involvement. Such lesions are initiated by pressure and often aided by some slight injury or by irritation from urine, feces or perspiration. While the lesion often occurs in paralyzed parts, it is by no means limited to patients with nerve involvement. The soft tissues over bony prominences are the common location of these ulcers, but with the widespread use of casts, splints and skin traction few parts of the body surface are exempt. Pressure produces a local ischemia with subsequent thrombosis, death of tissue and ulcer formation.

Prophylaxis is the ideal procedure. Such measures as frequently changing the position of the patient, massage, dusting powders including lead tannate,¹

Fig. 1—Decubitus lesions of patient with transverse cord lesion being treated with tannic acid.

cleanliness and protection of susceptible parts are of the utmost importance. Air cushions, rubber rings and pads aid in relieving pressure on the skin overlying bony prominences. Too much emphasis cannot be placed on the proper fitting of casts and splints and the careful application of skin traction. The mere removal of pressure from an involved region does not necessarily prevent the continued development or extension of the lesion. Not infrequently decubitus develops in spite of prophylactic measures. This is especially true of patients with cord lesions and bedridden, aged, emaciated and diabetic patients.

Once the lesion has developed, the recommended local treatments are numerous. A few therapeutic measures advocated are ointment of zinc oxide, scarlet red ointment, silver nitrate solution, ultraviolet rays, sunlight, dry heat and excision of the slough. More recently, sulphosalicylic acid² and thiocresol³ have

Read before the Chicago Surgical Society, May 5, 1933.

been recommended. The sulphur-containing radical is believed to stimulate epithelial growth. In severe cases and in extremely emaciated patients the continuous water bath⁴ has been used. Treatment to improve the general condition of the patient is important.

The gross similarity of decubitus to certain burns suggested the rationale of treating suitable lesions with tannic acid. Bligh⁵ treated an abrasion with tannic acid and Maddock⁶ used it to treat the surface from which Ollier-Thiersch grafts were removed.

A fresh 5 per cent aqueous solution of tannic acid is used.⁷ Seeger's⁸ method of neutralizing the solution to the pH of blood is worthy of trial. Treatment is begun at the first sign of tissue disturbance, preferably before the skin is broken. The wound and surrounding skin are cleansed and all crusts, debris and macerated skin, when present, are removed. If a blister is present, the elevated epithelium is removed aseptically. Lesions that may be kept exposed to the air are sprayed every hour with the tannic acid solution and between treatments the region is kept exposed to dry heat from electric lights or an electric hair drier. Wounds that must be dressed to be kept clean or to prevent direct

coagulum several times because of infection. Each time the crust is removed, the wound will be found to have decreased in size.

A virulent infection, profound necrosis of tissue and bone involvement are contraindications to the use of tannic acid in the treatment of decubitus. Should a virulent infection occur during the course of treatment, the crust should be removed and the lesion treated as any other similarly infected wound.

In a large series of cases, lesions of varying width and depth have been treated by this method. In some the skin was merely red when treatment was instituted, in others the tissues down to and including muscle were involved.

The method is simple and the results have been far more satisfactory than any other method used on control lesions. The results have been especially gratifying in lesions following cord injuries, bedridden diabetic patients and lesions under casts. Many of the arguments in favor of the use of tannic acid in the treatment of burns may be advanced in its use in the treatment of decubitus.

SUMMARY

The method of treating decubitus with a fresh 5 per cent aqueous solution of tannic acid is simple and efficient.

The presence of an infection is not necessarily a contraindication to its use.

Virulent infection, profound necrosis of tissue, and bone involvement are contraindications to the use of tannic acid in the treatment of decubitus.

25 East Washington Street

Fig. 2—Decubitus lesions of patient with diabetic gangrene of both legs being treated with tannic acid.

pressure are covered with sterile gauze, which is kept saturated with the tannic acid solution. Treatment is continued until a heavy protective coagulum is formed, which usually requires from twenty-four to forty-eight hours. Afterward no dressing is applied nor is sterile gauze used to keep the coagulum clean and dry. Healing occurs as in burns, and as the coagulum separates at the edge it is clipped away. Should it be necessary to remove the coagulum prematurely, it may be softened with sterile petrolatum.

The presence of an infection is not necessarily a contraindication to this method of treatment. In such cases the wound is treated with some suitable antiseptic solution until the infection is controlled, then the tannic acid is applied. If during treatment an infection occurs under the coagulum the crust should be removed, the wound treated as described and the tannic acid reapplied. Occasionally it is necessary to remove the

SECOND ATTACKS OF POLIOMYELITIS

REVIEW OF THE LITERATURE AND REPORT OF A CASE

T. B. QUIGLEY, MD

Resident Pathologist, Willard Parker Hospital

NEW YORK

It is probable that no infectious or contagious disease confers a permanent immunity in all cases. Authentic second attacks of scarlatina have been reported by McCrae,¹ of rubella by Maiselis,² of rubella by Widowitz,³ of pertussis by LeGendre⁴ and of parotitis by Friedjung.⁵ Recurrences of variola and typhoid, while rare, are well known. Second attacks of varicella are occasionally encountered although Widowitz³ found no instance in 524 cases of the disease.

Fourteen cases of second attacks of acute poliomyelitis are recorded in the literature. These must be distinguished from the relapses, which occur relatively frequently in every epidemic. In view of the demonstration by Kling, Petterson and Weinstedt⁶ of active virus in the nasal washings of patients seven months after the acute attack, it seems reasonable to consider every apparent second attack occurring within that time a relapse or exacerbation rather than a recurrence. Invariably, however, as Still⁷ has observed, these relapses take place within three months. A typical case

has been reported from this laboratory.⁶ An initial paralysis of both lower extremities in a youth, aged 18, was followed by apparent convalescence for five weeks. Respiratory difficulties then set in and death occurred on the forty-ninth day. At necropsy, lesions consistent with acute poliomyelitis were found in the medulla and lumbar cord. Apropos of such cases one of Flexner's⁹ early observations is of interest. Many of his monkeys remained comparatively healthy after a single intracerebral inoculation of virus, but after a second inoculation in the opposite hemisphere a few days later the full blown disease invariably developed. In these monkeys, as in human relapses, a sequence of events comparable to the Arthus phenomenon may have taken place. It is characteristic of most human relapses that the exacerbation is much more severe than the original attack.

The interval between the longest reported relapse and the earliest true recurrence is two years. Interpretation of the significance of this period cannot now be decided but must await the accumulation of more true second attacks. It is very likely, as has been suggested,⁷ that it represents the minimum duration of immunity.

Of the fourteen reported cases of true second attacks, eleven appear to be reasonably definite. In the cases of Oulmont and Baudouin,¹⁰ Eshner,¹¹ and Shepard,¹² the diagnosis of one or both of the attacks is obscured by such factors as insufficient data, concomitant disease, or trauma. Still⁷ in 1930 reviewed the literature and listed the most authentic cases in the form of a table. This is reproduced and brought to date by the addition of Neal's two cases.

As an addition to this list the following case is presented, the first on record in which the second attack was fatal.

REPORT OF CASE

HISTORY—J F, a white girl, aged 7 years, was admitted to the Willard Parker Hospital for the first time, Aug 15, 1931, at the height of the poliomyelitis epidemic of that year. The onset of her illness, two weeks before admission, was marked by drowsiness, fever and occasional vomiting. Within four days a definite paralysis of the left shoulder had developed, and a diagnosis of poliomyelitis was made by the local physician. Convalescent serum was administered intrathecally and intramuscularly by a representative of the New York City Board of Health. At the time of admission, the patient appeared normally developed, well nourished, alert and cooperative. Examination disclosed no abnormality save paralysis of the left deltoid muscle. A vague and ill defined weakness of the lower extremities appeared on the day after admission but vanished within twenty-four hours. The temperature remained within normal limits during the patient's six days in the hospital save for one transitory excursion to 100 F. At discharge, August 21, her condition was the same as at the time of admission.

No complication or other illness occurred during the following two years. Readjustment of the left shoulder muscles was rapid and loss of the deltoid occasioned little inconvenience.

In June 1933 two months before her second admission the patient contracted a mild pertussis without a whoop, which was treated with vaccine by the local physician.

July 31 1933 she was again admitted to the hospital. Two weeks before a mild indefinite infection of the upper respiratory tract had developed. A sore throat and slight difficulty in speaking had been present for four days. Vomiting and occasional spells of breathlessness, accompanied by slight cyanosis, began about thirty-six hours before admission. Mucus collected in the throat from time to time and drooling was observed. On the day of admission, two severe attacks of dyspnea occurred. During the attacks, the patient became very cyanotic.

Examination—On physical examination the patient was normally developed and well nourished and was in evident respiratory distress. Respirations were shallow, and speech was characterized by a nasal twang. The pharynx was congested and contained a fairly large quantity of mucus. The lung fields were clear. The usual neurologic signs were negative and there was no evidence of paralysis in the extremities save in the left shoulder. The cerebrospinal fluid was clear and under slightly increased pressure. It contained 15 monocytes per cubic millimeter, slightly increased albumin and globulin and moderately increased sugar.

A laryngoscopic examination was done shortly after admission. The arytenoids were slightly congested and edematous. The vocal cords were normal in appearance. Twice during the examination the child had an attack of dyspnea. During these attacks the right aryepiglottic fold and the right arytenoid were seen to pull inward and close the glottis.

The eegrounds were normal in appearance. Culture of the larynx yielded *Streptococcus viridans* and of the throat a mixture of *Streptococcus viridans* and haemolyticus. No organisms were recovered from the blood. The blood counts were within normal limits. A roentgenogram of the chest was interpreted as indicating possible slight bronchopneumonic infiltration in the axillary half of the right upper lobe. The temperature ranged between 102 and 105 F, and the child died two hours after admission to the hospital.

All the clinical observations were consistent with poliomyelitis, but this seemed very unlikely in view of the definite history of a previous attack.

Necropsy—This was performed twenty-one hours post mortem. The subcutaneous fat over the thorax and abdomen was approximately 3 cm in thickness. The tonsillar ring, including the faucial tonsils was hyperplastic and moderately congested. The larynx, vocal cords and laryngeal nerves were normal in appearance. Slight congestion was present in the bases of both lungs and there was beginning consolidation in the hilar portion of the right upper lobe. The heart was normal in appearance. The lymph nodes of the mediastinum were moderately

enlarged and congested. The liver was rather flabby in consistency. Its cut surface was a uniform pale muddy brown in color and had the granular appearance of moderate cloudy swelling. The spleen was soft in consistency and moderately congested. The stomach was somewhat dilated. Along the lesser curvature and about the pylorus were a few scattered areas of submucous hemorrhage. The Peyer patches of the ileum were markedly hyperplastic and congested, as was the lymphoid tissue about the ileocecal valve. Throughout the mesentery were scattered firm congested lymphatic nodes. These were most numerous in the region of the terminal ileum. The thyroid, pancreas, suprarenals, kidneys and genitalia were essentially normal in appearance.

The brain weighed 1,540 Gm. It was quite soft and markedly congested throughout. No points of hemorrhage, however, were seen. The substance of the medulla below the pons, "mushroomed" above its cut surface.

The dorsal blood vessels of the cord were intensely congested and rather tortuous, especially in the lumbar region. The cord itself seemed firm in consistency. On section the edematous somewhat mushy cord substance exerted or "mushroomed" above the cut surface. This occurred at all levels. The meninges were normal in appearance save for moderate congestion.

Microscopic Examination—Sections from various portions of the lungs included patchy areas of bronchopneumonia, atelectasis and emphysema. The blood vessels were intensely congested and in the sections from the right upper lobe the alveoli were nearly filled with serosanguinous exudate. The liver was moderately congested. Granular degeneration and fat infiltration were uniform and marked in the liver cells. The lymphoid tissue of the spleen was somewhat hypoplastic but various degrees of hyaline degeneration were present in the centers of most of the malpighian corpuscles. The splenic pulp was irregularly and intensely congested and the reticulo-endothelial element was hyperplastic. Extensive and uniform

Fig. 1—Nerve cell degeneration and neuronophagia in the pons at the level of the facial colliculus. (Formaldehyde fixation, hematoxylin and phloxin stain.)

granular degeneration was present in the tubular epithelium of the kidneys. The renal blood vessels were irregularly engorged and, in a few areas, hemorrhagic. The lymph nodes and Peyer's patches of the ileum were hyperplastic and congested. Their germinal centers exhibited various stages of necrosis and hyaline degeneration. The lymphoid element of the thymus was markedly hyperplastic and the thymic corpuscles were small and scattered. The thyroid was essentially normal save for moderate desquamation of the acinous epithelium. Sections of the heart, pancreas, suprarenals and pituitary were not remarkable.

In the right recurrent laryngeal nerve there was beginning axonal degeneration and phagocytosis in a very few places. A few of the ganglion cells were in various stages of degeneration and phagocytosis by microglia. Edema and congestion were roughly parallel at all levels of the brain stem and cord and most severe in the lumbar enlargement. A few small areas of hemorrhage were present in the sections through the lower portion of the pons, the medulla and the lumbar enlargement. Perivascular "cuffing" or infiltration of the Virchow-Robin spaces with lymphocytes was very prominent below the mid-portion of the pons. Nerve cell degeneration and neuro-

Fig. 2—The anterior horns in the upper cervical region of the cord. The number of motor cells is symmetrically reduced but microglial infiltration is most prominent on the left. (Formaldehyde fixation, hematoxylin and phloxin stain.)

phagia extended somewhat higher. About a third of the cells in a section through the midpons showed definite evidence of damage (fig. 1). There were irregularly distributed areas of softening and necrosis in both the white and the gray matter at all levels. Degeneration and neuronophagia of the cells of the anterior horn of Clarke's column and to some extent, of the posterior horn were very marked throughout the cord, but curiously asymmetrical (fig. 2). Degeneration of the fasciculi proprii and peripheral fiber tracts in the dorsal region was most prominent on the side of least anterior horn damage.

A residuum of the first attack was seen in the definite and symmetrical reduction in the number of cells in the anterior horns of the upper cervical region (fig. 2). Also sections stained by the methods of Hortega and Penfield revealed slight irregular gliosis in the lower medulla.

Sections of the meninges were not remarkable save for edema somewhat out of proportion to the degree of congestion.

The anatomic diagnoses were primary acute anterior poliomyelitis, secondary generalized lymphoid hyperplasia, hemorrhagic gastritis and bronchopneumonia.

COMMENT

The changes found at necropsy in this case were typical of those observed in the eighty-one fatal cases of poliomyelitis of the 1931 epidemic previously studied in this laboratory.¹³ Seventy-five per cent showed a similar mild hemorrhagic gastritis and in 86.7 per cent there was definite hyperplasia and congestion of the lymphoid tissue. While the greater part of this hyperplasia is undoubtedly a manifestation of the disease, the fact that in more than 30 per cent of the series the

faucial tonsils had been removed suggests some degree of constitutional hyperplasia in certain cases, at least. Although microscopic examination disclosed definite lymphoid hyperplasia in the thymus, the organ was somewhat smaller than is usually found in poliomyelitis. The average weight in the disease is almost always from 10 to 15 per cent greater than the average normal weight.

The pale, muddy, granular appearance of the cut surface of the liver, which defies accurate description, is felt in this laboratory to be almost peculiar to the disease. It is quite distinct from the diffuse cloudy swelling encountered in most infectious diseases but has no specific microscopic characteristics. On several occasions, when clinical opinions were at variance, a diagnosis has been ventured on the appearance of the liver alone and later confirmed by examination of the central nervous system.

The changes in the central nervous system in this case illustrate the oft observed lack of correlation between clinical and pathologic observations in acute poliomyelitis. No involvement of the extremities was apparent in the second attack, yet marked nerve cell degeneration, neuronophagia, congestion and edema were found at every level of the cord examined post mortem.

THE ETIOLOGY OF PRIMARY GRANULOCYTOPENIA (AGRANULOCYTIC ANGINA)

FREDERICK W. MADISON, M.D.

AND

THEODORE L. SQUIER, M.D.

MILWAUKEE

In 1922, when Schultz¹ described the syndrome which he called "agranulocytosis" and which later was called "agranulocytic angina,"² he suggested that it might be the result of a depressant effect on the bone marrow of an unknown micro-organism or possibly of an unknown chemical agent. Extensive search for an organism capable of producing such an effect has met little success. *Salmonella supestrifer*,³ *Bacillus pyocyaneus*⁴ and occasional organisms isolated from human cases have produced leukopenia with granulopenia in experimental animals but not in a manner entirely comparable to the syndrome seen in the human being. Nor has any organism thus far been found to occur constantly or even frequently in the clinical cases. Recently Dennis has attempted to incriminate focal infections by introducing various organisms in the experimental animal in a manner intended to simulate that type of infection in man and has found a tendency for granulocytopenia to develop. However, the results again are not entirely comparable to the clinical picture in man. Nor does it seem likely that focal infection, which presumably has existed throughout the human

era, can alone explain a clinical syndrome which is admittedly of very recent appearance.

Investigation of a possible chemical etiology has been somewhat more successful. Kracke⁵ has been able to reproduce the clinical picture accurately in the experimental animal by the use of benzene, ortho-oxybenzoic acid and hydroquinone. Turley and Shoemaker⁷ have shown that phenobarbital produces in dogs a marked reduction of the granulocytes. It has been shown that exposure to benzene in human beings causes in some marked depression of the bone marrow with especially marked effect on the granulocytic centers.⁸ It has also been established that a typical primary granulocytopenia occasionally may follow the administration of arsphenamine.⁹ Kracke⁶ observed that eight of nine patients with primary granulocytopenia seen by him had taken drugs of the coal tar series prior to the onset of their illness. He suggested that such drugs, because of the presence of the benzene ring, might be of etiologic importance and attempted unsuccessfully to produce the clinical picture in rabbits by the feeding of amidopyrine, acetphenetidin, peralga and dial.

Schilling¹⁰ has suggested that "since similar pictures may be obtained experimentally in anaphylaxis, an anaphylactic condition instead of an individual disease is possible." Pepper¹¹ in 1931 also stated that an allergic reaction might be involved in the disease.

CLINICAL OBSERVATIONS

In November 1931, while we were observing a patient with primary granulocytopenia,¹² we noted a sudden unfavorable change in the granulocyte level, which had been showing a satisfactory response. The granulocytes decreased abruptly, with a marked shift toward immaturity, and the patient became more toxic. Careful analysis disclosed the fact that he had been given a sedative dose of a barbituric acid derivative on the evening preceding the granulocyte decrease. We restricted the use of all drugs except opiates and after a rather stormy course he recovered. We later found that immediately preceding the onset of the illness he had taken allonal (allylisopropylbarbituric acid with amidopyrine) and that for some time previously had been in the habit of taking that drug frequently for restlessness and insomnia.

Shortly thereafter we saw a woman who likewise had a typical primary granulocytopenia. Two weeks previously she had had an acute cholecystitis, with a normal leukocyte response of 12,000 white cells, 10,000 of which were granulocytes. She had had no treatment except rest, restricted diet and two allonal tablets each night for two weeks. At the end of that period she was found to have a typical picture of primary granulocytopenia with 1,200 white blood cells and complete absence of granulocytes in spite of recovery from the cholecystitis.

These two cases so emphasized in our minds the importance of drugs in this disease that we have studied this relationship in all cases seen subsequently. In the interval since that time we have had the opportunity of studying twelve additional cases of primary granulocytopenia, which together with the first two are summarized in table 1. In each of the fourteen cases there was a definite history of the taking of amidopyrine in combination with a barbiturate, amidopyrine alone or in one instance, in combination with other drugs immediately prior to the clinical discovery of the granulocytopenia. Amidopyrine with a barbiturate had been used in seven of the cases, amidopyrine alone in six and amidopyrine in combination with other drugs in one

Patient 9, a man, aged 74, had tic douloureux and had been advised to use amidopyrine to control the pain. He had had no other medication or treatment and at the end of ten months a typical granulocytopenia developed. Patient 14, a woman, aged 34, admitted to the hospital for treatment of a severe arthritis, had a normal white count on admission. She was given 10 grains of amytal compound (amytal 3 grains [0.2 Gm.] with amidopyrine 7 grains [0.45 Gm.]) daily for four days, no medication for four days, then 10 grains of amytal compound daily for four days, at the end of which time she was found to have granulocytopenia. Recently Costen¹³ has reported three cases, in two of which he noted a similar striking relation to medication.

TABLE 1—Summary of Fourteen Cases of Primary Granulocytopenia Showing the Relationship of Drugs Containing Amidopyrine to the Onset and Outcome of the Disease

Patient	Age and Sex	Occupation	Health Prior to Onset of Granulocytopenia	Medication Prior to Onset of Granulocytopenia	Treatment										Outcome	Comment
					Blood Count Prior to Onset		Blood Count at Onset						Barbiturates and Amidopyrine Continued			
					Total W B C	Granulo cytes	Total W B C	Granulo cyte	Trans fusion	Pent nucleotide	Yellow Bone Marrow					
1	40 ♂	Physician	Insomnia	Allonal	5 000 to 7 000	Normal	1 100	0	Yes	Yes	Yes	0	Recovered (2 mos.)	Two mild recurrences induced recurrence after 6 grains of amidopyrine		
2	60 ♀	House wife	Insomnia	Allonal			1 100	0	Yes	0	0	Yes	Died after 1½ months	Had chronic granulocytopenia with frequent acute recurrences		
3	80 ♀	House wife	Acute chole cystitis	Allonal	1. 000	10 000	1 000	0	0	Yes	0	0	Died in 36 hours	No bone marrow response		
4	48 ♀	House wife	Rectal abscess	Allonal	8 000 to 10 000	Normal	1 400	0	Yes	Yes	0	Yes	Died in second recurrence			
5	40 ♀	House wife	Rectal abscess chole cystitis	Allonal	8 000	5 860	1 000	0	Yes	Yes	0	Yes	Died in first recurrence	Phenobarbital allonal and amytal with amidopyrine after recovery from acute attack		
6	22 ♂	Chemist	Pharyngitis	Sodium amytal amidopyrine			1 000	0	Yes	Yes	0	Yes	Died in first recurrence			
7	65 ♂	None	Headaches following influenza	Amidopyrine	9 600	5 700	1 000	0	0	Yes	0	Yes	Died	Slight bone marrow response		
8	42 ♀	Clerk	Rectal fistula	Neonal amidopyrine	8 000	6 700	200	0	Yes	Yes	0	0	Died	No evidence of bone marrow response		
9	74 ♂	Laborer	Tic douloureux	Amidopyrine			0	120	0	Yes	0	0	Recovered (4 mos.)	No recurrence		
10	20 ♀	Nurse	Back strain	Amidopyrine			2 900	50	0	Yes	0	0	Recovered (10 mos.)	No recurrence		
11	48 ♀	House wife*	Pharyngitis	Amidophen + phenobarbital			1 100	0	0	Yes	Yes	0	Recovered (8 mos.)	No recurrence		
12	58 ♀	House wife	Pharyngitis tonsillitis	Amidopyrine	5 000 to 6 000	Normal	1 400	0	0	Yes	0	0	Recovered (7 mos.)	No recurrence		
13	61 ♀	House wife	Cerebral hemorrhage	Allonal	10 900	7 825	1 100	0	0	Yes	0	Yes	Died	No bone marrow response		
14	34 ♀	House wife	Arthritis	Amytal with amidopyrine	5 000	4 300	1 000	0	0	Yes	0	0	Recovered (3 mos.)	Amytal with amidopyrine and amidopyrine alone induced recurrences (chart)

† Amidopyrine acetphenetidin caffeine hyoscine

The relation between the use of these drugs and the development of the typical blood picture was quite striking in several patients. Patient 7, a man, aged 65, on admission to the hospital for treatment of severe headaches had a total white count of 9,600 with 5,700 granulocytes. He was given a normal diet and had no medication or treatment except 10 grains (0.6 Gm.) of amidopyrine daily. No additional symptoms were observed until at the end of eleven days he became acutely ill and was found to have a total white cell count of 1,600, with complete absence of granulocytes. Patient 8, a woman, aged 42, admitted to the hospital for surgical care of an anal fistula and abscess, had a normal white count on admission. She had received no medication except neonal (n-butylethylbarbituric acid) compound (neonal with amidopyrine) in varying doses for restlessness and at the end of three weeks no granulocytes were present in the peripheral blood.

Additional suggestive evidence of the etiologic relationship of these drugs to granulocytopenia was seen in the clinical course of the patients in our group. Although the methods used for stimulation of granulopoiesis were similar in all patients, consisting of transfusions, nucleotide or yellow bone marrow extract, amidopyrine was strictly prohibited in eight of the cases but its use was permitted in six others because its harmful effect was not fully appreciated. In the group of six cases in which amidopyrine alone or in combination with barbiturates was used for the relief of pain or restlessness during or after the acute illness, the mortality has been 100 per cent in spite of the fact that four recovered from the acute attack. In the other group of eight patients the use of these drugs was prohibited. Only two of these patients have died.

(mortality 25 per cent) and the granulocytopenia in each of the fatal cases was so extreme when the diagnosis was made that no bone marrow response to stimulation was obtained, and death occurred in thirty-six hours and four days, respectively. All others in the group recovered from the acute attack and are well after an interval varying from two years to three months. Five of these patients have had no recurrence. One patient has had three mild recurrences, at least two of which are known to have followed the taking of amidopyrine.

EXPERIMENTAL OBSERVATIONS

To obtain further evidence of the ability of these drugs to depress the granulocytes, drugs suspected of etiologic relationship were given to each of two patients who had clinically recovered from acute granulocytopenia. Patient 1, a man, aged 40, who eighteen months previously had had his initial attack following the use of allonal and who constantly had had a normal granulocyte count for ten months, was given 5 grains (0.3 Gm) of amidopyrine. In three hours he had a chill with return of symptoms of the acute illness and in twelve hours the granulocytes had almost completely disappeared from the peripheral blood.

Patient 14, a woman who had arthritis and developed granulocytopenia after the administration of amytal compound and who had had a normal granulocyte count for three weeks after the acute attack, was given two capsules (amytal 3 grains, amidopyrine 7 grains) of this drug. Two hours after administration the granulocyte count had fallen from 6,850 to 3,200 and after twelve hours to 1,200. Subsequently there was a gradual return to normal as shown in the accompanying chart. As a control, a patient with a similar type of arthritis, but who had not had granulocytopenia, was given the same dosage of amytal compound with no significant change in the granulocyte or total white count. Three weeks later the patient who had had granulocytopenia after amytal compound was given 3 grains of amytal alone and blood counts were made at corresponding intervals. No significant alteration in the total or granulocyte count was seen. After another three weeks interval, during which time the granulocytes remained at a normal level, she was given 5 grains of amidopyrine and again a severe depression of the total and granulocyte counts occurred. Before administration of the amidopyrine the granulocyte count was 7,400, sixteen hours later it was 3,100, after which it gradually returned to normal.

In these two patients amidopyrine or amidopyrine in combination with amytal (amytal with amidopyrine) produced a temporary marked depression of the granulocytes. In the second patient amytal alone failed to produce this effect. It seems to us reasonably certain that continued administration of drugs containing amidopyrine to these two patients would have resulted in a recurrence of the typical primary granulocytopenic state.

Following our clinical observations in 1931, and before we were aware of the work done by Kracke,⁶

we attempted to produce the clinical picture of granulocytopenia in rabbits by the administration of suspected drugs. Eleven rabbits were given allylisopropylbarbituric acid with amidopyrine (allonal) by mouth in doses of from $2\frac{2}{3}$ grains (0.16 Gm) to 24 grains (1.55 Gm) daily, four rabbits were given the same drug intraperitoneally and four rabbits were given from 1 to 2 grains (0.065 to 0.13 Gm) of amidopyrine alone intravenously and intraperitoneally. One rabbit that had been given an average of 20 grains (1.3 Gm) of allonal daily by mouth showed a rather abrupt drop in both the total and the granulocyte count on the twenty-fifth day, following which there was a progressive fall until death occurred on the thirtieth day (table 2). Preceding death there was complete absence of granulocytes in the peripheral blood and the blood picture was characteristic of primary granulocytopenia except for a moderate anemia. At necropsy there were no grossly abnormal conditions found save that the bone marrow was absolutely lacking in cells of the granular series. None of the other rabbits showed the blood picture of granulocytopenia.

Total white blood count (solid line) and granulocyte count (broken line) in case 14, showing onset of granulocytopenia following administration of amytal with amidopyrine (amytal compound), and the subsequent effect of a single small dose of A amytal with amidopyrine B amytal alone, and C amidopyrine alone.

COMMENT

It is generally recognized that primary granulocytopenia is a relatively new clinical syndrome. Although a few apparently authentic cases preceded Schultz's description in 1922, it is only since that time that the disease has attracted wide attention. We do not believe that the small number of cases reported prior to that time was due to diagnostic error, for the blood picture is so characteristic that it could scarcely be overlooked. Even in the five years subsequent to Schultz's report, Kastlin¹⁴ was able to find only forty-three cases in the literature. In the six years since Kastlin's report, however, the incidence has increased rapidly, so that now there are more than 500 cases on record. That period of rapid increase coincides almost exactly with the increase in the use of drugs containing a combination of amidopyrine with a barbiturate. Furthermore, in our cases, as in cases recorded in the literature, the syndrome has appeared in those people who are most apt to be taking drugs—physicians, physicians' wives,

¹⁴ Kastlin G J. Agranulocytic Angina. *Am J M Sc* 173: 799 (June) 1927.

nurses and patients of physicians. In most instances it has occurred in individuals who have had some type of illness, usually associated with pain, and were under medical care prior to the onset of the granulocytopenia. In every patient in our series the onset of the granulocytopenia was preceded by the taking of amidopyrine or amidopyrine combined with a barbiturate. In a group of eight cases in which the further use of these drugs was prohibited, the mortality was 25 per cent. In a group of six cases in which the use of these drugs was continued, the mortality was 100 per cent. We have been able to induce a marked decrease in granulocytes by the administration of a single small dose of these drugs to patients who had recovered from an acute granulocytopenia. It is interesting but of

festations of drug hypersensitivity. The widespread use of arsphenamine and amidopyrine as compared with the small incidence of primary granulocytopenia suggests that drug hypersensitivity is responsible for the bone marrow reaction seen in those cases. The rapidity of the decrease of the granulocytes and the tendency to spontaneous return to normal after the administration of a single small dose of amidopyrine to individuals known to be susceptible further suggests the same type of reaction. A similar profound temporary leukopenia has been demonstrated in anaphylactic shock. It is our conception therefore that the bone marrow and blood changes in primary granulocytopenia are the result of the repeated administration of certain drugs (amidopyrine with a barbiturate,

much less significance, that we have produced fatal granulocytopenia in one rabbit by the long continued oral administration of allylisopropylbarbituric acid with amidopyrine.

We believe that this evidence indicates that these drugs are etiologic factors in primary granulocytopenia in man. Such a relationship already has been demonstrated for arsphenamine and less typically for benzene. We feel that amidopyrine, especially in combination with a barbiturate, must be added to that group and is probably of more importance than either of the others. Whether the presence of the barbiturate results in a synergistic action or otherwise influences the effect of the amidopyrine remains to be determined. Amidopyrine contains a benzene ring as do arsphenamine and benzene. Whether the presence of the benzene ring is of primary importance, as suggested by Kracke, likewise remains to be determined. If such is the case, a number of similar drugs may be incriminated later.

Drugs of the type represented by amidopyrine are recognized as frequently responsible for various mani-

festations of drug hypersensitivity. The widespread use of arsphenamine and amidopyrine as compared with the small incidence of primary granulocytopenia suggests that drug hypersensitivity is responsible for the bone marrow reaction seen in those cases. The rapidity of the decrease of the granulocytes and the tendency to spontaneous return to normal after the administration of a single small dose of amidopyrine to individuals known to be susceptible further suggests the same type of reaction. A similar profound temporary leukopenia has been demonstrated in anaphylactic shock. It is our conception therefore that the bone marrow and blood changes in primary granulocytopenia are the result of the repeated administration of certain drugs (amidopyrine with a barbiturate,

SUMMARY

1 The increase in incidence of primary granulocytopenia (granulocytic angina) has paralleled the increase in the use of drugs containing amidopyrine and especially those containing amidopyrine with a barbiturate.

2 The disease has appeared most frequently in persons apt to be taking drugs—physicians, nurses, and those directly under the care of a physician.

3 In each of fourteen patients the onset of primary granulocytopenia was directly preceded by the use of amidopyrine alone or in combination with a barbiturate.

4 The mortality in a group of six patients who continued the use of drugs containing amidopyrine was

100 per cent In a group of eight patients who did not continue the use of these drugs, only two died, and both of these died in the initial attack

5 The administration of a single dose of amidopyrine to each of two patients who had recovered from the acute disease was followed by a rapid profound fall in granulocytes

6 One rabbit given allylisopropylbarbituric acid with amidopyrine (allonal) by mouth in relatively large doses showed an abrupt drop in granulocytes and died on the thirtieth day Preceding death there was complete absence of granulocytes in the peripheral blood Seventeen other rabbits given allonal or amidopyrine showed no significant change in the blood picture

7 We believe that amidopyrine alone or in combination with a barbiturate is capable of producing primary granulocytopenia in certain individuals who have developed sensitivity to the drug

8 We believe that the appearance of primary granulocytopenia following the use of such drugs may be the result of an allergic or anaphylactoid drug reaction¹⁵

SPONTANEOUS LATE DESCENT OF THE TESTIS

CARL B DRAKE, MD
ST PAUL

While making yearly examinations during the past six years of the boys at a country day school in St Paul I was early impressed by the relative frequency of cases of undescended testis The boys ranged in age from 9 to 19 and out of some 260 boys examined in all (the school enrolment averaging about 140) eleven boys showed this developmental defect at some time during this period of observation

The usual method of palpation with invagination of the scrotum, the examining finger reaching the external inguinal ring, failed to locate the missing testis in any of these eleven boys These were in my opinion cases of undescended testis The condition was left sided in six cases, right sided in four cases and bilateral in one case

The question was raised whether the parents should be notified of a developmental defect about the existence of which most of the parents presumably were ignorant At the suggestion of the headmaster of the school, to whom the frequency of the condition was nothing new, I decided simply to observe developments

This policy of observation has been enlightening Ten of these twelve missing testes have spontaneously and rather miraculously descended to the scrotal position This late spontaneous descent occurred, roughly, once in the tenth year, twice in the eleventh, twelfth, thirteenth and fourteenth years and once in the sixteenth year The two persisting cases are in boys now 14 years of age

Special attention was paid in the examination of these eleven to determine (1) the position of the late descended testis (2) lack of testicular development as evidenced by its size, (3) the association of hernia

and (4) evidence of an associated physical or mental inferiority

All except one of the late descended testes have reached the normal position low in the scrotal sac and are normal in size In the boy with a bilateral late descent, the right testis appeared in the scrotum in his fourteenth year and the left in his sixteenth year While the right testis is normal in size and position, the left is slightly smaller than the right and at present is midscrotal in position The presence of a hernia associated with a late descent of a testis was not determined in a single case, although it is said to be always present There was no evidence of any lack of physical development in any of these eleven boys I am assured by the headmaster that none of them show any evidence of being below the average in their studies

OBSERVATIONS ELSEWHERE

I have been unable to find any published record of observations extending over a period of several years as to spontaneous late descent of the testis The question arose whether my experience in this small group of boys had been unusual In an effort to answer this question I wrote to the medical examiners of eleven boys' schools that enroll boys before the age of puberty, making inquiry as to their experiences I received six replies One reported that three boys with undescended testes had been operated on, among 238 boys examined in 1929, and three cases of unoperated undescended testicle in 243 boys examined in 1931 Another examiner stated that he found "relatively few" cases but that the "vast majority" seen before puberty descend spontaneously Another reported seeing very few cases and that very few boys had been operated on Another found one case in a school of 100 boys during a four year period

As a result of the examination in the fall of 1932, of 268 boys ranging in age from 8 to 18 in a boys' school in Boston, Dr Donald S King made the following observations, which I have his kind permission to report Of these 268 boys, sixteen had or had had at one time an undescended testis Of the sixteen cases, eight were bilateral cases, seven right sided and one left sided Spontaneous descent had occurred in three of the eight bilateral cases, both testes having descended This occurred once in the twelfth, once in the thirteenth and once in the fourteenth year Four of the eight one sided cases had shown a spontaneous descent, one each in the tenth, eleventh, thirteenth and fourteenth years An orchidopexy had been performed in two unilateral cases, one in the fourteenth and one in the fifteenth year, the testis in each case being smaller on the side operated on Of the persisting cases, five were bilateral (two boys aged 10, one boy aged 11 and two boys aged 12) and two were unilateral (one boy aged 10 and one aged 12)

This report shows an experience quite similar to mine, except as to the distribution of right sided, left sided and bilateral cases It is rather striking that there is no boy in this series over the age of 14 and that only two of the sixteen boys had been operated on Attention might be called to the fact that spontaneous descent occurred relatively late in childhood in this series also

Through the courtesy of Dr Henry Wireman Cook I was permitted to examine the records of some 532

¹⁵ We wish to express our appreciation to Drs F D Murphy, H J Birk and others of our colleagues for permission to include their cases in this series
Read before the Ramsey County Medical Society, St Paul May 29 1932

boys ranging in age from 9 to 19, enrolled during the past fifteen years at a private boys' school in Minneapolis. I found ten cases of undescended testicle recorded. Of these, seven had spontaneously descended, one in the eleventh, three in the twelfth, one in the thirteenth and two in the fourteenth year. Two of the remaining three boys had been observed just once, and the third had a persistence of the defect at the age of 16.

INCIDENCE

The incidence¹ of undescended testis in army recruits has been reported as 5 in 1,000 in Scotland (1916-1917), 2 in 1,000 in Austria (1870-1882) and 3 in 1,000 in the United States at the time of the World War. Failure in descent is said to occur more frequently on the right side possibly owing to the fact that normally the left testis is the first to descend. In about 20 per cent of cases the condition is said to be bilateral.

TREATMENT

To judge from the literature on the subject surgical treatment for undescended testis is almost universally advised. Bevan,² who first operated for the condition in 1898, is the exponent of early operation, preferring the first or second year of life. As recently as 1929 he said that the legend of spontaneous descent between birth and puberty is entirely erroneous and that in a large experience he has never seen a definite example of this kind. He does not recommend operation before puberty when the testis can be pressed into the scrotum, and he leaves alone certain individuals after puberty but recommends operation for practically all under puberty and the majority of those from puberty to the age of 20.

Hugh Cabot,³ writing in 1931 recommended operation before the age of 9 years but stated that even after puberty operation may save the gland. He thinks it fortunate that these patients see the surgeon early.

Most writers recommend orchidopexy before puberty. Wangenstein⁴ mentions the almost universal practice of orchidopexy and thinks the age from 8 to 11 best. He⁵ also stated as recently as 1932 that instances in which descent may occur between birth and puberty are so few that operation need not be postponed to the hope that the testis may spontaneously descend.

Higgins⁶ believes that, when the testis cannot be found, operation is indicated.

Complications such as accompanying hernia, torsion of the cord, malignancy of the testis and inflammation of the appendix testis are generally admitted indications for operation. The possibility of such rare complications arising is scarcely an indication for operation. A malignant condition of the testis occurs more frequently in the undescended testis. It is comparatively rare, however, and has developed following orchidopexy and even in normally descended testes. The surgeons apparently do not consider the possibility of malignancy a reason for operation.

RESULTS FROM OPERATION

Goetsch,¹ reporting in 1931 on the position of the testis at the end of the operation in thirty-six cases, described six in a low scrotal position, sixteen in a midscrotal, seven in a high scrotal and seven in the lower inguinal position. A follow up of fifteen cases examined from four months to seven and a half years after operation showed six low scrotal, two midscrotal, five high scrotal, one in a low inguinal position and one missing. The operated testis had developed normally in one case.

In 1926, Burdick and Coley⁷ reported on 537 orchidopexies in 482 patients under the age of 17 performed at the Hospital for the Ruptured and Crippled from 1891 to 1924. Accurate estimations of end results were impossible because of incomplete data as to the location and size of the testis. From the figures given, only 114 of the 537 testes were classed as scrotal in position, with an additional 64 upper scrotal and 77 outside the inguinal ring. The authors think it fair to assume that 50 per cent of operations prove satisfactory as to position of the testis and that about 15 per cent are normal in size after operation.

Turner⁸ reports 70 per cent of fifty-three cases with the testis well down after operation.

Pasten⁹ reports 32 per cent of good results in thirty-one cases.

Coley,⁹ reporting in 1919 with special reference to end-results following operation, stated that in only a small percentage was the testis in the lower scrotum several years later.

If Wangenstein's opinion that only a low-lying scrotal testis will develop normally after puberty is correct, operative results must be judged on this basis.

The Torek operation of fixation of the undescended testis through the scrotum to the thigh has been devised to hold the testis well down in the scrotum more effectively and has been favorably reported on. I have been unable to find a report of final results obtained from this operation in any series of cases.

Certainly, surgical procedures have not been very successful.

COMMENT

What, if any, problem is presented by the undescended testicle? Cosmetic considerations may be summarily dismissed.

Psychic effect from failure of a testis to descend scarcely merits serious consideration.

It is established that even bilateral nondescent of the testis has no deleterious effect on the physical or mental development.

Functionally, one normal testis is as efficient as two.

A malignant condition occurs more often in an undescended than in a descended testis but at that is of rare occurrence.

In contradiction to Blund Sutton's statement that a testis fails to descend because it is abnormal, Wangenstein⁵ states that the undescended testis before puberty is indistinguishable macroscopically and microscopically from the normal.

CONCLUSION

Although my personal observations of the spontaneous late descent of undescended testes in boys under

7 Burdick, C. G. and Coley, B. L. Abnormal Descent of the Testicle. *Ann Surg* 81: 867 (Dec.) 1926.

puberty is admittedly limited, my experience, taken in conjunction with the observations of the school physicians previously referred to, justifies certain conclusions

The unilateral uncomplicated undescended testis does not present any surgical problem in spite of considerable medical literature to the contrary. The great majority descend spontaneously by the age of 14 (many in the twelfth, thirteenth and fourteenth years), become normal in size and eventually lie low in the scrotal sac. The only case that should be considered a surgical problem is the bilateral one persisting to the fourteenth year or the unilateral case presenting complications.

I have been led to call attention to the spontaneous late descent of the great majority of undescended testes by the persistence of the urge to operate on these boys, evidenced in recent surgical articles. An article by Newell¹⁰ refers to a legend prevalent in the South that operation for undescended testis should be delayed until after puberty, as the testis will probably descend at or just after puberty. He says "When we consider what little foundation such a legend has in fact and what perfect opportunity there has always been for accurate observation and refutation, it is profoundly depressing that this legend should continue to exist among medical men." On the contrary, it seems remarkable to me that the truth of this legend has not been generally appreciated by the medical profession.

THE TREATMENT OF ERYSIPELAS IN CHILDREN

A COMPARATIVE STUDY SHOWING THAT BEST RESULTS ARE OBTAINED WITH THE USE OF ULTRAVIOLET RADIATION

LOUIS M. NIGHTINGALE, M.D.

AND

SAUL STARR, M.D.

BROOKLYN

Erysipelas in infants still remains a dread disease, with a mortality rate usually well over 50 per cent. Serum therapy is the only treatment that has been repeatedly productive of results in infants, as shown by reports of consecutive series of cases. Despite reports of good results with ultraviolet therapy in adults, no study of this method of treatment in infants and children has yet been published. We hope by this preliminary report to make up for this deficit.

From the literature on the subject we may state the following approximations. When treated by only local applications, from 60 to 90 per cent of infants with erysipelas die. When serum is used, the mortality rate is brought down to from 40 to 60 per cent. Of sixteen cases reported by Foote,¹ there were three deaths of thirteen infants under 1 year of age—a low mortality rate of 23 per cent, while at Kings County Hospital in the last five years there have been thirty-four deaths of fifty-nine infants—a rate of 59.3 per cent. Elev's² recent study of thirty-three serum-treated cases reported

eleven deaths of twenty-five infants, a mortality rate of 44 per cent.

In recent years, scattered reports have been published concerning ultraviolet therapy for erysipelas. In the United States, Ude³ particularly has been advocating this method and in 1930 presented the first large series of such cases. Stimulated by his report we began similar work on all the children with erysipelas admitted to the pediatric service at Kings County Hospital. Every child under 12 years of age admitted for erysipelas since November 1932 was given ultraviolet therapy alone. Frankly, we were rather skeptical at the outset. However, our results soon were so gratifying—especially in comparison with serum-treated cases over the past five years—that we decided to analyze our figures and present our results to date.

HISTORICAL SUMMARY

Since the American writers on the subject have omitted doing so, a brief summary of the development of ultraviolet therapy for erysipelas may not be amiss.

Petenyi⁴ in 1921 treated fourteen infants under 10 months of age, with only two deaths. He irradiated with less than an erythema dose.

Of 100 cases, Czepa⁵ in 1922 reported good results with ultraviolet therapy in "almost every case."

In 1927, Becker⁶ reported that two infants, and later⁷ eight infants under 1 year of age, received ultraviolet therapy for erysipelas, three of these were under 1 month of age and the only death in his series occurred in this group. He advised one and a half erythema doses to an area extending to 4 cm beyond the erysipelatous border.

Ude and Platou³ first reported their results with ultraviolet therapy of erysipelas in 1930. Ude's⁸ latest report includes 147 cases, in which ultraviolet therapy was used in both adults and children. His mortality rate for this group was about 7 per cent, as compared with a 71 per cent mortality rate for serum-treated cases as reported by Symmers.⁹ Ude and Platou's results with serum therapy and roentgen therapy were not as good as in their ultraviolet-treated series, in either adults or infants. Only five infants were treated with ultraviolet rays alone, with a mortality rate of 40 per cent. We shall refer again to their statistics. The dosage employed was twice a mild erythema dose, with the burner at 8 inches, so as to concentrate the shorter wave lengths on the erysipelatous area.

Davidson¹⁰ in 1932 reported a smaller series of cases treated by ultraviolet irradiation with good results.

Various authors have studied the infancy cases with the idea of giving mortality statistics for various age groups of infants. In general, infants under 6 months of age have a mortality rate of 60 per cent with only local treatment.

Based on a series of cases in forty-eight infants under 1 year, Schaffer and Rothman¹¹ give the following figures for untreated cases: 80 per cent mortality rate for infants under 1 month, 53 per cent for infants from 1 to 6 months, and 47.6 per cent for infants from 6 to

12 months Based on fourteen serum-treated cases, there was 100 per cent mortality (one case) for infants under 1 month, 25 per cent for infants from 1 to 6 months, and 20 per cent for infants from 6 to 12 months. Our larger series of fifty-nine serum-treated infants give results (table 1) that are no better than Schaffer and Rothman's untreated series.

TABLE 1—Study of Deaths in Infants by Age Groups

Age	Serum Treated			Ultraviolet Treated		
	Cases	Number	Per Cent	Cases	Number	Per Cent
0-1 month	6	5	83.3	7	1	14.3
1-4 months	23	14	60.8	5	0	0.0
5-8 months	14	10	71.4	7	3	42.8
9-12 months	16	5	31.2	4	0	0.0
13-24 months	12	2	16.6	5	1	20.0

METHOD OF STUDY

Since November 1932 we have treated with ultraviolet rays fifty-one children under 12 years of age with erysipelas, of these, twenty-three were infants under 1 year of age. Four infants and one older child also received serum therapy, of these five, three died. These patients were treated early in our work when we had less confidence in ultraviolet irradiation rather than make a separate classification of these five cases we have added them to both the ultraviolet and the serum treated series.

For comparison we have reviewed all the pediatric admissions since January 1929. In all there were 130 patients with erysipelas, of these, 101 received serum treatment alone and 16 received local treatment the remainder receiving various forms of treatment.

Such a division of cases as in table 2 makes the groups too small for a comparative study of all the methods of treatment. We have therefore compared our ultraviolet group with the results in the 101 serum-treated cases. Considering the fact that serum treatment has given perhaps better results than all previous forms of therapy, and certainly better than simply local applications, results that are as good as or better than with serum treatment will establish the efficacy of ultraviolet therapy.

TABLE 2—Summary of Cases

Treatment	Over 1 Year		Under 1 Year	
	Cases	Deaths	Cases	Deaths
Ultraviolet	27	1	19	7
Ultraviolet and serum	1	1	4	2
Serum	46	2	5	32
Local treatment	5	0	11	6
Mixed treatment	7	0	6	4
Total	86	4	35	51
Mortality		4.6%		53.6%

TECHNIC OF THERAPY

The serum-treated patients received various commercial antisera in dosage as suggested by Simmons. On admission, each patient received 10 cc of serum intramuscularly, this dose was repeated every twelve to twenty-four hours until the disease was under control. An average of four ampules of serum per patient was used. Most of the group were also given wet magnesium sulphate dressings locally over the erysipelatous area.

Early in our study the ultraviolet therapy was much as that suggested by Ude and Platou. As soon as admitted, the child received a single dose of ultraviolet radiation—about one and a half erythema doses for the older children, slightly less for the infants. The ultraviolet rays were directed to an area extending from 1 to 2 inches beyond the spreading border, the burner being set 10 inches from the patient. If the area could be exposed only from two directions, the overlapping was permitted.

However, we soon noticed that, especially in the infants, the dose of ultraviolet radiation had to be repeated frequently for continued spread of the lesion and persistence of a high temperature. Our routine was then changed to three doses of one and a half erythema doses on successive days, regardless of the clinical course. Rarely did we have to repeat the ultraviolet irradiations. We saw no ill results from the treatment in our entire series.

In many of the infants treated with ultraviolet rays early in our series, transfusion was performed, especially if complications were present. However, seeing no particular benefit in these complicated cases and

TABLE 3—Analysis of Results*

	Total Cases	Total Mortality	Corrected Mortality	Before Treatment (All Cases)	Before Treatment (Recovered Cases)	Mortality (Recorded Cases)
Over 1 year						
Serum	47	3 cases 6.4%	2 cases 4.2%	2.5 days	2.5 days	2.9 days
Ultraviolet	25	2 cases 8.0%	1 case 4.0%	2.2 days	2.2 days	6.6 days
Under 1 year						
Serum	9	31 cases 77.8%	2 cases 22.2%	2.3 days	1.5 days	1.0 days
Ultraviolet	23	9 cases 39.1%	7 cases 30.4%	2.7 days	2.4 days	1.6 days

* Four infants and one older child who were treated with both serum and ultraviolet rays are considered as belonging to both series.

finding that in most of our uncomplicated cases recovery occurred without transfusion, we discontinued it as a routine procedure.

ANALYSIS OF CASES

We divided our patients into those over 1 year, "older children" and those under 1 year of age, "infants." Most writers on this subject use 2 years as the dividing line, but infants between 1 and 2 years of age have a mortality rate closer to those over 2 than those under 1 and should be classed with the older children. (This increases our mortality in the infants as compared to other authors but gives more accurate statistics.)

Mortality in Older Children—The rate in older children was close to that of adults, as reported by Simmons in 1932. He reports a series of 3,311 cases mostly adults, treated with serum with a mortality of 71 per cent. In our series of eighty-six older children our mortality is 46 per cent. Of the eighty-six cases, forty-seven treated by serum alone gave a mortality rate of 64 per cent, while twenty-eight were treated by ultraviolet rays alone with a death rate of 71 per cent. Of the deaths in this group the respective ages are 13 months, 17 months, 21 months and 3 years, the two older patients are mongolian idiots. In general, the older the child, the better the prognosis.

Mortality in Infants—In the group of ninety-five infants our total mortality was 53.7 per cent. This is somewhat better than that reported by Ude in January

1931 He had thirty cases with a mortality of 63.3 per cent. In our series serum therapy was used in fifty-nine cases with a mortality of 59.3 per cent, and in twenty-three cases ultraviolet therapy was employed with a death rate of only 39 per cent. In Ude's series ultraviolet therapy alone was employed in five cases with a 40 per cent mortality, roentgen therapy in seven with 85 per cent mortality, roentgen therapy and serum in two with a 50 per cent mortality, and ultraviolet and serum therapy in six, with a 50 per cent mortality. We have too few cases to discuss in which other methods of therapy were used, and the foregoing results may be compared with ours by reference to table 5.

We corrected our death rate by eliminating the cases in which death did not seem due to erysipelas per se but to a complicating feature, such as pneumonia or mastoiditis. An example of what we mean is shown by a case admitted with a diagnosis of pneumonia and erysipelas. Clinically the erysipelas cleared in five days but the child died four days later of the pneumonia. Our mortality rate, when corrected, becomes 30.4 per cent in ultraviolet and 47.4 in serum cases.

Morbidity in Older Children—As may be seen in table 3, there is considerable difference in the duration of disease. The average morbidity for the forty-seven older children treated with serum was 89 days and in the twenty-eight ultraviolet cases 66, a difference of 23 days. The average days before treatment in both groups was about 2.5 days.

Morbidity in Infants—In the infants under 1 year of age the figures are still more striking. The average number of days before treatment is coincidentally the same, 2.3. The serum cases had a fifteen day morbidity and the ultraviolet cases a 7.6 day morbidity, a 50 per cent decrease in the length of illness. As can be seen in table 1, by dividing the cases into smaller age groups, most of these groups show better results for ultraviolet rays.

TABLE 4—"Ideal Cases"

	Total Mortality	Corrected Mortality	Morbidity
Over 1 year (treated within 24 hours)			
Serum treatment	1 of 11 cases 9%	0	78 days
Ultraviolet treatment	0 of 8 cases 0%	0	44 days
Under 1 year (treated within 48 hours)			
Serum treatment	17 of 31 cases 54.8%	14 of 31 cases 45.1%	89 days
Ultraviolet treatment	4 of 11 cases 36.3%	2 of 11 cases 18.1%	63 days

Early Treated Cases—Since it has been shown that the earlier the treatment is instituted the shorter the course of the disease, we decided to study a group of early treated serum and ultraviolet cases, which we will term "ideal cases." In the older children given serum within twenty-four hours of onset, the mortality was 9 per cent and the morbidity was reduced from 89 to 78 days. In those in which ultraviolet rays were used the mortality was nil and the drop in morbidity was from 66 to 44 days. It can be seen that the average duration of the ultraviolet cases was three days less than the serum cases.

Among the infants we had too few treated within twenty-four hours and used those treated within forty-

eight hours as our ideal cases. In these, the mortality rate was 54.8 per cent for serum and the morbidity was 89 days whereas it was fifteen days for the entire group. The irradiated series had a mortality of 36.3 per cent with a morbidity of 63 days whereas it was 7.6 for the entire group. Again there is a difference of about three days' illness between ultraviolet and serum cases.

The number of complications that occurred in all groups was less in the cases treated earlier and in general was less in the irradiated cases than in those treated by serum.

TABLE 5—Miscellaneous Cases

Type of Treatment	X Rays		Magnesium Sulphate		X Rays and Serum	
	Under 1	Over 1	Under 1	Over 1	Under 1	Over 1
Number of cases	1	2	11	7	5	4
Number of deaths	0	0	0	2	4	0
Average days before treatment	5	3	2.3	2.5	2	1.5
Average morbidity in days	15	6	8	8	8	8

Of special interest is the youngest child in the series. This was a premature infant weighing 4 pounds 13 ounces (2,182 Gm.) and was 19 days old. The baby had a definite erysipelas of the face, which was treated with ultraviolet rays. The temperature came down to normal by crisis in three days and the child was discharged six days later weighing 5 pounds 2 ounces (2,325 Gm.).

SUMMARY

1 Ultraviolet therapy alone gives better results in both infants and older children than does serum therapy.

2 As with serum, the earlier ultraviolet therapy is given, the better will be the results.

3 There was no difference in severity observed between the facial and the body type of erysipelas, except that the genital type was usually severe.

4 Translating our figures into more graphic statements, we find:

A In older children,

(a) Death was almost nil in previously healthy children over 2 years of age, and when it occurred it was due to complicating features such as mongolism, pneumonia, and the like.

(b) The child is ill about six and a half days but if treated within twenty-four hours of onset is ill only four and a half days (three and a half days after treatment).

B In infants,

(a) One out of five die despite early treatment for an uncomplicated erysipelas, if not treated early, one out of three die.

(b) The presence or appearance of a complicating feature, such as pneumonia, mastoiditis, gastro-enteritis, jaundice, spells almost certain death. Local abscesses are much less important.

CONCLUSION

1 Ultraviolet therapy to date has been (a) most successful, (b) least dangerous, and (c) least expensive.

2 On this basis, ultraviolet irradiation should be put above serum therapy in the treatment of erysipelas.

Clinical Notes, Suggestions and New Instruments

HEMOCHROMATOSIS IN A WOMAN

H. F. WECHSLER, M.D., NEW YORK

Hemochromatosis is not an uncommon disease. Its occurrence in women, however, is a rarity. My purpose in the present communication is to place on record another of these exceptional cases.

REPORT OF CASE

History—M. L., a white woman, aged 47, an American housewife, first seen, June 7, 1930, complained of polydipsia and loss of weight. In May, 1929, a trace of sugar had been discovered in the urine which, in spite of a restricted carbohydrate intake, had rapidly mounted. In July she entered a hospital in Portland, Maine, where she was finally rendered sugar free on a weighed diet of 150 Gm of carbohydrate, 60 Gm of protein, 90 Gm of fat and 4 units of insulin at bedtime. Since that time, although she adhered strictly to her diet, sugar had appeared irregularly in the urine and she had lost 7 pounds (3.2 Kg). Polydipsia had been present for several months. Her appetite was good and her bowels were regular. There were no cardiovascular or respiratory symptoms. She had not noticed any discoloration of the skin as she was accustomed to lead an outdoor life but her husband thought that she had become "deeply tanned" in the past year. On two occasions, two years and again six months previously, she had suffered from marked frequency and urgency of urination. These attacks lasted for several days and disappeared spontaneously.

Prior to her present illness she had always been in splendid health. She drank an occasional glass of beer. She had three children, aged 17, 14 and 11 years, respectively. There had been no miscarriages. Her menses were normal.

Her mother died at the age of 62 of diabetes mellitus; her father died at 40 of meningitis. One sister aged 50 was alive and suffering from essential hypertension.

Examination—The patient was undernourished and had the appearance of being chronically ill. She weighed 98 pounds (44.5 Kg). The skin was universally light brown with the exception of the face, neck, forearms and the back of the hands which were of a much deeper brown. Several small red papules were present in the flush area of the face.

The eyes and eye grounds were normal except for a definite subicteric tinge to the sclerae. The mucosa of the mouth showed no pigmentation. The tongue was clean and the pharynx normal. The teeth were in a good state of repair.

There was no glandular enlargement and the thyroid was not palpable.

The lungs were clear and the heart was normal. The blood pressure was 120 mm systolic and 80 mm diastolic.

The abdomen was protuberant with marked distasis of the rectus muscles and a moderate umbilical hernia. The liver extended a hand's breadth below the costal arch in the mid clavicular line. The surface was smooth, firm and not tender and the edge was rounded. The spleen was palpable three fingerbreadths below the costal arch. It was freely movable, firm and not tender. No other organs or masses were palpable. There was no ascites.

Pelvic examination was negative except for a moderate cystocele and rectocele. Rectal examination revealed the presence of internal hemorrhoids. The extremities were normal and the reflexes were normal.

Examination of the urine (a twenty-four hour specimen) showed a faint trace of albumin, sugar 0.5 per cent, the absence of acetone and a moderate number of white blood cells microscopically. Chemical examination of the blood plasma revealed sugar, 224 mg per hundred cubic centimeters, urea nitrogen, 12.5 mg, uric acid, 3.0 mg, creatinine 0.5 mg, carbon dioxide capacity, 49 volumes per cent. The blood count was red blood cells, 4,750,000; platelets, 250,000; hemoglobin (Sahli), 94 per cent; white blood cells 6,000; neutrophils

66 per cent, lymphocytes, 34 per cent. The bleeding and clotting times were normal. The Wassermann reaction of the blood was negative. The icteric index was 35, and the direct Van den Bergh test gave a delayed positive reaction. Fragility of the red blood cells was diminished. Hemolysis began at 0.33 per cent and was not complete at 0.25 per cent. The Ewald test meal showed free hydrochloric acid 8, total hydrochloric acid 20. Roentgenograms of the gastro intestinal tract were essentially negative. A biopsy of the skin (hematoxylin-eosin and iron stains) was done. A small amount of hemosiderin was present in the corium in the form of dustlike granules, both free and in the chromatophores. It was most abundant about the coil glands. Hemofuscin was found in much greater quantity in the corium.

Course—On a diet of 180 Gm of carbohydrate, 60 Gm of protein and 100 Gm of fat totaling 1,914 calories, and 10 units of insulin, she remained sugar free for two months. The blood sugar, which had been ranging between 110 and 160 mg per hundred cubic centimeters, then rose to 304 mg and the urine contained 1 per cent of sugar. The insulin was increased to 15 units. In spite of the fact that she adhered to the same carefully weighed diet her tolerance steadily diminished and with almost monotonous regularity the insulin had to be increased about every two months in order to desugarize her system. By November, 1931 she was taking 40 units of insulin, 25 before breakfast and 15 at bedtime. Her weight varied between 98 and 105 pounds (44.5 and 47.6 Kg).

From June to September 1930 she was given an intensive course of sodium thiosulphate intravenously with no appreciable influence on the size of the liver and spleen or on the diabetes. Although the Wassermann reaction was negative, a therapeutic test of bismuth and iodides was tried for several months with the same results.

In January 1931 she complained of abdominal distention and diarrhea. Pancreatic extract and the elimination of raw fruits, bran cereals and coarse vegetables from the diet controlled these symptoms. They were apt to return after even slight dietary indiscretions, however.

Complete urinary retention with overflow dribbling occurred in April 1931. Cystoscopy revealed a markedly hypertrophied and trabeculated bladder and a single diverticulum about the size of a plum arising from its posterior wall. Pyelograms showed a moderate bilateral hydronephrosis. Spinal fluid withdrawn by lumbar puncture was under normal pressure. The cell count, globulin, sugar, Wassermann and colloidal mastic tests were completely negative. It was the cystoscopist's opinion that the condition was congenital in nature. With frequent bladder irrigations and strychnine sulphate by mouth, the bladder paralysis was finally overcome only to recur six weeks later. The second attack was very refractory to treatment until a vaginal pessary was inserted. The symptoms were immediately and permanently relieved.

July 5, 1931 she had a severe hematemesis and a second one occurred on the 30th. Blood transfusions had to be resorted to in each instance. September 24, she complained of weakness and dyspnea on exertion. Examination revealed a moderate secondary anemia associated with melena.

Several months previously, a small, freely movable mass the size of a walnut had been palpated in the upper outer quadrant of the left breast. Because of the hopelessness of the underlying condition, it was ignored. However, about this time the mass began to grow rapidly with adherence to the skin and palpable axillary nodes. Pain and a bloody discharge from the nipple were also present. After various consultations an operation was decided on, because of the pain and suffering that would ensue should the condition be allowed to go unchecked. A radical mastectomy was performed, November 15, from which she made an uneventful recovery, only to succumb to a severe hematemesis, December 10. Examination of the breast tumor showed it to be a duct cell carcinoma with extensive metastases to the axillary glands.

COMMENT

Although it is unfortunate that an autopsy could not be obtained, the triad of progressive diabetes, cirrhosis of the liver (enlarged liver and spleen, subicterus and esophageal varices)

and pigmentation plus the demonstration of hemosiderin and hemofuscin in the skin, admit of no other diagnosis

The general frequency of hemochromatosis is not easily determined, as the disease is now so well known that few cases are reported, and practically every pathologist has one or more unpublished ones in his files. That Bork¹ in 1928 was able to gather only 111 cases is therefore misleading. Its extreme rarity in women is universally conceded. Modern textbooks, however, are either content with a vague statement in this regard or cite from two to four cases. In a rather complete survey of the literature I have been able to collect twelve cases,² three of which (Berg, Murri, and Moeller and Hutton) are doubtful. Excluding these three, it would appear that hemochromatosis in the male is about ten times as frequent as in the female. Since the female cases are probably all reported, the true ratio is undoubtedly much greater.

A CASE OF ATTEMPTED SUICIDE WITH INSULIN

JOSEPH T. BEARDWOOD, JR., M.D., PHILADELPHIA

The average diabetic patient is a well behaved member of society seldom given to acts of violence or attempts to inflict injury on himself or others. Indeed, aside from the tendency to deceive his physician in regard to his cooperation, he is apt to be an exemplary citizen. A careful search of the literature for the past ten years has revealed no case in which such a massive dose of insulin was taken and only one case¹ in which insulin was taken with suicidal intent, and in this case only 20 units was taken. This was but 12 units more than the patient had taken as a daily dose to control his diabetes. He promptly repented of his deed and took sugar within fifteen or twenty minutes and did not suffer any reaction.

Hypoglycemia may produce death, and even mild degrees of depression of the level of the blood sugar may be followed by fatal complications, usually coronary occlusion, as has been shown by Parsonnet and Hyman.²

Extreme degrees of hypoglycemia with blood sugar values below 30 mg per hundred cubic centimeters of blood are usually incompatible with life. These facts show the need of caution in reducing the blood sugar of a patient with diabetes. "Insulin shock" is a condition not to be regarded lightly, and it should be part of the training of every diabetic patient to recognize the premonitory symptoms of hypoglycemia and to take steps to overcome it.

REPORT OF CASE

Mrs. A. B., aged 50, white, admitted to the receiving ward of the Presbyterian Hospital at 7 p. m., April 15, 1933, had been found by a park guard lying on the ground in pain and complaining of feeling sick. When first seen by the resident on duty in the receiving ward she was obviously weak and partially unconscious. Her face was flushed, the veins in the neck were prominent and the pulsations of the carotids were forceful. Her body was cold and bathed in a cold perspiration. The heart was slightly enlarged to the left and the rate was rapid. There were also slight tremors present in all the extremities. No evidence of paralysis could be elicited. The pulse rate was 100, the temperature 94 F.

The patient could be aroused by repeated questioning, and she hysterically related that she had taken 400 units of insulin.

about three quarters of an hour before admission. Blood was collected immediately for a blood sugar test and she was immediately given 30 Gm of dextrose by mouth, shortly following which she became slightly more rational and again reiterated that she had given herself 400 units of insulin with suicidal intent.

In her handbag were found one 10 cc bottle of U-20 insulin that contained about 1 cc of its original contents and one 5 cc bottle of U-40 insulin which was practically empty, together with a standard insulin syringe. There were also several letters addressed to friends expressing regret for her act and stating that she was sorry to have taken the money to purchase the insulin and one other letter, which she requested to be buried with her.

Examination at the time of admission showed no subcutaneous swelling or hemorrhagic points that might identify the sites of injection, although there were several spots of blood on the clothing, which lent credence to her report.

On admission the blood sugar was 64 mg per hundred cubic centimeters of blood.

At 7 15 she was given 90 Gm of dextrose by mouth and at this time she was still sweating profusely, depressed and somewhat hysterical.

At 7 30 she complained of pain in the small muscles of the feet, and she was given 20 Gm of dextrose by vein and 60 Gm by mouth. This feeding was repeated every hour.

At 10 o'clock the temperature was 94.3, the pulse rate 96. The sweating continued, and there was noticed for the first time some drooping of the right side of the face.

At midnight she complained of severe pains in the legs and of a dull headache. She was mentally clear. Her color was poor. The temperature was 96, the pulse rate 96, the blood sugar 55 mg per hundred cubic centimeters. (She had had up to this time 360 Gm of dextrose by mouth and 20 Gm by vein.) She was given 75 Gm of dextrose intravenously and 120 Gm by mouth.

At 2 a. m. she was still complaining of severe pain in the feet and legs, 60 Gm of dextrose was given every hour.

At 8 a. m. the patient felt well except for a slight headache. Sugar appeared in the urine for the first time, and the blood sugar was 278 mg per hundred cubic centimeters. She was then transferred to the metabolic service for standardization.

COMMENT

In a period of twelve hours the patient had received a total of 1025 Gm of carbohydrate. She must have required at least fifteen injections to administer the 390 units of insulin that she took.

When the patient was admitted to the metabolic service a more complete history of her past medical life was obtained, which may be briefly summed up. The patient had known for seventeen years that she had diabetes and remained on a qualitative diet until the advent of insulin, when she was standardized and placed on insulin. She had been carefully followed during this time and was last standardized on a diet of 60 Gm of carbohydrate, 60 Gm of protein and 80 Gm of fat and with this diet she required 52 units of insulin a day. In August 1925 the gallbladder was removed and following this she developed pneumonia, from which she recovered after a stormy convalescence. In 1927 she developed a gangrenous ulcer of the foot, which responded to conservative treatment. Lately she had been greatly depressed because of financial worries and finally decided to commit suicide by taking insulin. She borrowed money from a friend to secure a large enough supply to do the deed properly.

Laboratory examinations gave the following information. The Wassermann reaction was 4 plus, the Kahn reaction 3 plus. The red blood cells numbered 3,220,000, the white blood cells 9,000 and the hemoglobin was 64 per cent. The differential count was essentially normal.

The specific gravity of the urine was 1.018. There was a trace of albumin. Tests for sugar, acetone and diacetic acid were negative. Microscopic examination showed from 50 to 75 white blood cells per high-powered field, with many hyaline casts.

The transverse diameter of the heart measured 18.5 cm, the transverse diameter of the thorax 33 cm.

2 Parsonnet, A. E. and Hyman, A. S. *Ann. Int. Med.* 4: 1247 (April) 1911.

The patient was restandardized on a diet of 120 Gm of carbohydrate, 60 Gm of protein and 120 Gm of fat, yielding a total of 1,800 calories, and with this required 30 units of insulin a day. The cystitis improved by local treatments and antisyphilitic therapy was started. Because of an apparent underlying psychosis the patient was transferred to another institution for observation with the diabetes well controlled.

Doubling the carbohydrate allowance in the diet seems to have had the effect of decreasing the total insulin requirement.

There was another case of attempted suicide in Philadelphia in which a physician who did not have diabetes gave himself a large dose of insulin and lost consciousness during the reactions. He was given dextrose intravenously and recovered. I was unable to ascertain the amount of insulin taken. As there was no laboratory examination made, a complete report of this case is impossible.

TREATMENT OF LYMPHOGRANULOMA INGUINALE WITH BOUILLON FILTRATE

WILLIAM A. THOMAS, M.D. AND EARL R. MCCARTHY, M.D.
CHICAGO

In view of the chronicity of course and the various forms of treatment advised in lymphogranuloma inguinale we feel justified in reporting a single case because of the unusual rapidity and completeness of healing that followed treatment with autogenous filtrate.

A man aged 31, seen at the office in October 1932, had a tender swelling in the right groin draining since an incision had been made seven weeks previously. This had begun nine weeks before, with a small firm lump in the right groin aching somewhat. During the subsequent two weeks it became larger and softer, turned red and was incised draining thick yellow pus. Fever persisted for ten days the patient feeling ill. It then improved for a time, but both local and general conditions became worse with increased activity. From five to six weeks preceding the onset, the patient noticed several small red pimples on the penis, which were cauterized. There had been gonococcal urethritis and prostaticitis three years before and a urethral discharge one year before. There was no history of syphilis, no infection or trauma of the right leg and the Wassermann reaction was negative. The Frei test taken later was positive.

The patient entered the Presbyterian Hospital October 28 for treatment.

In the right groin there was a pullet-egg sized mass with an incision about 1 inch long into it. The edges of the incision and the skin for a distance of half an inch were dusky red. A thin serosanguineous discharge drained from the incision. Medial and lateral to this mass several hazelnut-sized masses were felt. The involved area was about 2 inches long by 1 inch wide and extended laterally directly over and below Poupert's ligament. This entire area was very tender to palpation and very indurated. On the upper surface of the glans penis were several pinhead-sized brown spots which the patient stated followed the cauterization of some pimples three months previously. At the base of the glans on the right undersurface was a small weeping excoriation to which mercuriochrome had been applied. There were no palpable masses in the left groin and rectal examination was negative. General physical examination was negative. The temperature was 98.6 F.

After five days' application of hot saturated magnesium sulphate dressings to the right groin every two hours—no appreciable improvement having taken place—the affected area was widely opened under local anesthesia, November 4. At operation many long sinuses were found filled with dirty granulation tissue and extending laterally along Poupert's ligament to the enlarged inguinal nodes and downward to the enlarged femoral lymph glands.

Bacteriologic cultures were made and the sinuses carefully curetted and the wound was loosely packed with iodoform gauze but not sutured. For five days the treatment with hot dressings was resumed, with daily packing of the incision but the wound showing small disposition to heal the patient was

discharged from the hospital with dry dressings and a small iodoform wick under the edges.

Meanwhile, a bouillon filtrate was being prepared after the method of Besredka of the Pasteur Institute. Cultures of a hemolytic streptococcus and of a variety of anaerobic or partially anaerobic organisms were obtained from the wound. These were transplanted separately to flasks of dextrose broth and incubated for from eight to ten days after which time no further growth could be obtained by reinoculation of the filtered broth. The filtrates so obtained were pooled and on November 15 no appreciable improvement having been observed, the incision was packed with plain gauze and saturated with the filtrate. November 18, the wound was much cleaner, with healthy granulations and healing. The patient then resumed his occupation of traveling salesman and, following instructions, packed the wound twice daily and saturated the packing with the filtrate.

January 16 when he was next seen, the large indurated masses of glands had completely disappeared, drainage had ceased and there remained only a small area in which epithelialization had not occurred. Less than a week later the wound was completely healed.

Naturally one draws no extensive conclusions from a single case. However in view of the increasing interest in the action of filtrates and the rather astonishing results obtained in the filtrate treatment of *Trichomonas vaginalis* the result in this case justifies further trial of filtrate therapy in lymphogranuloma inguinale.

Presbyterian Hospital

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
H. A. CARTER, Secretary

ANNUAL MEETING OF THE COUNCIL ON PHYSICAL THERAPY

The Ninth Annual Meeting of the Council on Physical Therapy was held at the headquarters of the American Medical Association Friday and Saturday, January 12 and 13. Dr. Harry E. Moe of Chicago was reelected chairman and Dr. Frederick J. Gwenslen, vice chairman.

Some of the questions and problems considered at this meeting were the rental of radium and the rental and sale of radon; the status of ultraviolet therapy, the efficacy of high frequency currents and the undergraduate and postgraduate instruction in physical therapy. In the opinion of the Council, more stress might well be placed on postgraduate education of the profession. A tentative program was considered whereby committees within the interested local or state societies might be established whose duties would be to take charge of physical therapy educational activities in the local group. The Council believed that these committees cooperating with the Council might arrange for special speakers and seminars in physical therapy. It was considered vitally important for the Council to arouse greater interest in the state societies throughout the country as rapidly as might be possible.

After many critical reports and surveys had been reviewed the Council revised its "Regulations to Govern Advertising of Ultraviolet Generators to the Medical Profession Only" and released it for publication.

Through its representative, the Section on Ophthalmology of the American Medical Association asked the Council to consider favorably the investigation of spectacle lenses and ophthalmologic appliances. The Council agreed to go forward immediately with this work. To begin with, special articles relating to the investigation of devices and methods already completed will appear in the Council columns, and at a later date Council reports on the investigations of apparatus will also be prepared for publication.

The Council is planning to publish a report on its investigations regarding hyperpyrexia. Certain dangers in the fever

treatment of disease are recognized and it is contemplated that the article will contain information concerning the pathology and physiology of hyperpyrexia

Grants for the aid of research have been utilized to the utmost capacity. The Council was pleased to note that most of the recipients have published the results of their investigations

WITHDRAWAL OF ACCEPTANCE OF THE FILTERAIRE

The Filteraire, manufactured by the Davies Air Filter Company, New York City, is a small air filtering machine formerly known as the "Stoppollen." A report of acceptance appearing in THE JOURNAL, May 31, 1930, page 1760, described the makeup and operation of the Stoppollen. Since then, however, the manufacturer has not only changed the name of the device but has entirely altered its construction. The firm was asked to cooperate with the Council by furnishing a new model for examination and report. This it did and also supplied the Council with advertising matter for review and criticism.

The results of the investigation showed that certain claims appearing in the advertising matter must be regarded by the Council as unwarranted or misleading. A report adopted by the Council was sent to the manufacturer pointing out the objectionable statements and nonconformities to the Official Rules of the Council. In a reply the firm agreed to revise the advertising matter. It was changed and in a measure some of the objectionable statements were either revised or completely deleted. However, a careful examination of the matter showed that not all of the objectionable statements or claims had been deleted or otherwise made acceptable, hence this report.

In the aforementioned advertising matter, claims are made to the effect that the Filteraire can "shut out dirt and dust" and that the "street noises are excluded from the room." The Council investigation showed that the unit will filter out most of the dirt and dust, but since the unit itself is installed in a window, it could not be expected to shut out any more noise than is excluded by an ordinary closed window.

The following is recorded in the pamphlet:

Agar Petri dishes were exposed directly in the path of air forced through Filteraire. Similar dishes were exposed simultaneously to unfiltered air. Exposure was for periods of 30 and 60 minutes. Tests were made on 15 separate days. After 72 hours of incubation the dishes were examined. Those exposed to the filtered air showed no growth whatsoever. Those exposed to open unfiltered air showed innumerable colonies.

The firm was asked to submit data of bacteriologic tests supporting these claims. The evidence made available was not critical and the Council did not accept the aforementioned statement.

The claim that patients suffering from hay fever will obtain relief for the entire day of twenty-four hours by remaining in a room for eight hours, more or less, made free of pollen by means of the "Filteraire" ("Stoppollen") or any other air filtering device is not accepted by the Council. All clinical evidence coming to the attention of the Council demonstrates conclusively that patients are relieved only when they remain in a filtered atmosphere. The symptoms of hay fever return to the patient when again subjected to air polluted with pollen. If conclusive evidence substantiating the claim is available, it has not reached the Council. Promotional literature of this kind constitutes an appeal to the public with arguments that are unscientific and may harmfully enhance a feeling of false security on the part of the public.

Although the Filteraire may be a suitable air filter for a small office or bedroom, the Council on Physical Therapy voted to withdraw the apparatus from its list of accepted devices because (1) the results of the investigations by the Council do not agree with the claims advanced for the apparatus, (2) the Davies Air Filter Company violates the rules of the Council on Physical Therapy by including misleading claims in advertising matter. The company was informed of the conclusions of the Council and the action proposed but apparently the firm did not care to alter its present marketing policy.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

ANTIMONY THIOGLYCOLLAMIDE (See New and Nonofficial Remedies, 1933, p 62)

The following dosage form has been accepted:

Ampules Solution Antimony Thioglycollamide 0.4 per cent 10 cc
Manufactured by Hynson Westcott and Dunning Baltimore

ANTIMONY SODIUM THIOGLYCOLLATE (See New and Nonofficial Remedies, 1933, p 63)

The following dosage form has been accepted:

Ampules Solution Antimony Sodium Thioglycollate 0.5 per cent 10 cc
Manufactured by Hynson Westcott and Dunning Baltimore

PRELIMINARY REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

PAUL NICHOLAS LEECH Secretary

GASTRIC MUCIN

The use of gastric mucin in the treatment of peptic ulcer was introduced by S. J. Fogelson¹ of Northwestern University, following the work of Ivy and Oyama² and of Lim³ on gastric secretion.

Gastric mucin has been presented for the consideration of the Council by Armour and Company, Frederick Stearns & Company, and the Wilson Laboratories. These firms manufacture this product under license from the Mucin Committee of Northwestern University.

Gastric mucin has been the subject of a number of investigations, both on animals and on patients. The approach to this problem was excellently planned by the group in Chicago. They obtained on experimental dogs good evidence of the value of mucin in preventing ulcer⁴. (Further evidence as to the role of mucin has been provided by others⁵). The Northwestern group prevailed on commercial houses to prepare a satisfactory product and established a method of controlling the purity and checking the physiologic activity⁶. They next arranged to have a number of competent gastro-enterologists⁷ try the effects on a large group of patients with peptic ulcer. The results of all these studies have been submitted to the Council. All these clinicians were enthusiastic about mucin but were fairly conservative, admitting a certain percentage of failures. They recognized the fact that the large majority of patients with peptic ulcer may improve on any one of several methods of treatment and that spontaneous remissions may occur. This probably

explains the fact that, for every form of ulcer treatment, claims of about 70 to 80 per cent of cures are made. Attention should perhaps be concentrated on those cases that have failed to improve after prolonged treatment with the older methods. The clinical reports of Drs. Brown, Atkinson, Fogelson and their associates contain a large number of such cases in which improvement occurred when mucin was taken in fairly large doses.

A number of protocols and letters have been submitted concerning physicians who suffered from peptic ulcer and agreed to test mucin. From a careful perusal of these reports it is evident that most of the physicians believed that they were helped by this preparation. A good many of them had difficulty in swallowing the viscous material but ultimately overcame this by developing an adequate technique.

When a new therapeutic method for peptic ulcer is introduced, numerous reports soon appear from practitioners who have failed to obtain satisfactory results. A review of the recent literature shows this to be the case with gastric mucin. Smithies⁸ believes that the favorable effect of mucin may be due to the fact that it limits pepsin production and has an antitryptic action. He suggests that it inhibits appetite through constant nausea and unattractive taste. Smithies emphasizes the fact that Fogelson, Anderson and Brown employed not only mucin but also liquid or soft smooth diets. His conclusions are: "In our experience, management by Fogelson's gastric mucin has proved unsatisfactory."

Bloch and Rosenberg⁹ of the Michael Reese Hospital came to the following conclusions:

1. Gastric mucin probably acts not through its acid combining power but by virtue of its demulcent effect.

2. Experience with thirty mucin-treated patients as compared with fifteen ulcer cases in which other forms of treatment were given, shows that some will not continue its use because of the disagreeable taste and certain untoward symptoms. In others, prolonged administration effects no relief whereas other forms of treatment are successful. In still others relief is temporary and followed by a relapse. In the remainder, relief occurs with mucin when other forms of therapy fail.

3. Further refinements in its manufacture may widen its scope of usefulness in the treatment of peptic ulcer.

Fantus,¹⁰ referring to an article by Fogelson makes the following editorial comment: "Experience of others is not nearly as favorable. Many patients object to the nastiness of the dose."

At a symposium on mucin therapy held before the Chicago Medical Society,¹¹ the difficulties inherent in a study of this sort and the necessity for thorough clinical trial were emphasized. The summarized data presented on a large number of patients, in whom doses of gastric mucin totaling from 90 to 100 Gm. a day were used, indicate considerable promise for this form of therapy despite an admitted certain percentage of failures.

Of a total of 223 intractable ulcer patients treated by clinicians throughout the United States, as summarized by the Mucin Committee, the majority were said to have been rendered symptom free or improved.

The Council's referee has tried gastric mucin in a limited number of ulcer cases in his clinic and has found it difficult to induce the patients to continue its use. It is very viscous and the taste is somewhat difficult to disguise but perhaps it is no worse than many of the liver preparations used in the treatment of pernicious anemia.

In summary, it appears that, although the early studies indicated beneficial results in a fairly large number of patients with peptic ulcer that had failed to respond to other methods of treatment, later publications have emphasized that there are limitations to this form of therapy. Gastric mucin is a viscous, unpalatable preparation and many patients refuse to continue

treatment, nevertheless, the product appears to be of value in a number of patients that have not done well on usual ulcer therapy.

The Council therefore decided to postpone further consideration of gastric mucin pending the accumulation of additional evidence as to the therapeutic usefulness of this substance.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING AN ECCESSARY CORRECTION OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR OFFICIAL FORMULATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION. RAYMOND HERTWIG, Secretary.

VAN CAMPS PURLED SPINACH (ADDED SALT)

Manufacturer—Van Camps, Inc., Indianapolis

Description—Sieved spinach, slightly seasoned with salt, largely retaining the natural minerals and vitamins.

Manufacture—Freshly cut spinach is carefully inspected and trimmed and any defective leaves are eliminated, it is washed in a cylinder equipped with high pressure sprays of water, blanched by immersion in boiling water for a minimum time necessary for softening withdrawn, dipped into cool water drained, sieved in a steam atmosphere through a screen with openings of a size to produce the desired fineness and texture, salted, heated, and filled into enamel lined cans, which are sealed and processed.

Analysis (submitted by manufacturer) —	per cent
Moisture	97.7
Total solids	7.3
Ash	1.6
Sodium chloride	0.8
Est. (ether extract)	0.3
Protein (N x 6.25)	2.3
Reducing sugars (as dextrose)	0.4
Sucrose (copper reduction method)	0.0
Crude fiber	0.8
Carbohydrates other than crude fiber (by difference)	2.2
Alkalinity of ash (cc. of normal acid per gram ash)	5.4
pH	6.5

Calories—0.2 per gram, 6 per ounce

Statement—The method of preparation efficiently protects the natural vitamins.

Claims of Manufacturer—Is easily digestible, has a smooth consistency and supplies bulk without roughness. A good source of iron, calcium and of base forming minerals.

MCCORMICK'S BEE BRAND CURRY POWDER

Manufacturer—McCormick and Company, Inc., Baltimore.

Description—Spice mixture including turmeric, coriander seed black pepper, mustard flour, cumin, fenugreek seed, caraway seed, cassia, cayenne pepper, cloves, mace and ginger.

Manufacture—Definite proportions of the spice ingredients prepared as described for McCormick's Bee Brand Allspice (THE JOURNAL Oct. 28 1933 p. 1393), are mixed and automatically packed in tins.

Analysis (submitted by manufacturer) —	per cent
Moisture	9.5
Total ash	5.3
Acid insoluble ash	0.4
Volatile ether extract	2.7
Nonvolatile ether extract	7.0
Protein (N x 6.25)	11.8
Starch (diastase method)	14.7
Crude fiber	15.6
Carbohydrates other than crude fiber (by difference)	48.1

Claims of Manufacturer—All ingredients conform to the definitions and standards of the United States Department of Agriculture.

**POST'S 40 PER CENT BRAN FLAKES WITH
OTHER PARTS OF WHEAT
(MALT SYRUP, SUGAR AND SALT)**

Manufacturer—Postum Company, Inc., Battle Creek, Mich.
Description—Toasted, flaked, cooked wheat bran (40 per cent bran) with adhering endosperm, flavored with malt syrup, sugar and salt

Manufacture—Whole wheat is cleaned and milled to remove the germ and a material portion of the endosperm or flour section. The bran material with adhering endosperm is admixed with malt syrup, sugar, salt and water in cooking drums and cooked under steam pressure. The cooked product is air cooled, flaked, toasted and automatically packed in cartons.

Vitamins—Contains 43 Sherman vitamin B units per ounce

Claims of Manufacturer—Contributes indigestible bulk to the diet for counteracting constipation due to insufficient bulk in the diet. A good source of vitamin B and of iron.

**HERSHEY'S BAKING AND DRINKING
CHOCOLATE
NOT SWEETENED**

Distributor—Chocolate Sales Corporation, Hershey, Pa.

Manufacturer—Hershey Chocolate Corporation, Hershey, Pa.

Description—Ground cacao nibs or "chocolate liquor" in cake form.

Manufacture—Selected cacao beans are freed of foreign material by sieving and air-blast, are roasted to develop flavor and aroma, and are quickly air-cooled, cracked and hulled. The nibs are separated from shells, germ and foreign material by screening and air-blast and are ground between burr stones by water cooled steel rolls and finally by corrugated granite rolls, the grinding lasting ninety-six hours. The resultant "chocolate liquor" is automatically deposited in molds, chilled and solidified. The cakes of chocolate are removed from the molds and automatically wrapped.

**VAN CAMPS PURFED APRICOTS
CONTAINS SULPHUR DIOXIDE SWEETENED**

Manufacturer—Van Camps, Inc., Indianapolis

Description—Sieved dried 'sulphured' apricots, slightly sweetened with sugar, largely retaining the vitamins and all the minerals of 'sulphured' dried apricots.

Manufacture—Choice dried sulphured apricots are carefully inspected to eliminate unsuitable material, washed twice and soaked over night in cold water. The swelled apricots and juice are transferred to a steam jacketed closed kettle heated at approximately 91 C until soft and are drawn off and sieved in a steam atmosphere through a screen with openings of a size

to produce the desired fineness and texture. A definite amount of sugar and hot water are added for sweetening and adjusting the consistency. The batch is heated to filling temperature, immediately filled into enamel lined cans and processed.

Analysis (submitted by manufacturer) —		per cent

Claims of Manufacturer—Of smooth consistency, supplies bulk without roughness.

**LIGHT'S BEST OVEN PERFECT FLOUR
(PHOSPHATE ADDED—BLEACHED)**

Manufacturer—The Light Grain and Milling Company, Liberal, Kan.

Description—Hard winter wheat standard patent flour containing added calcium acid phosphate (0.5 per cent), bleached.

Manufacture—Selected hard winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended, bleached with nitrogen trichloride (one-seventh ounce per barrel), and finally mixed with 0.5 per cent calcium acid phosphate.

**DAVIDSON'S SPUN BREAD SLICED (WHEAT
BREAD A BLEND OF SELECT WHITE AND
WHOLE WHEAT FLOURS)**

Manufacturer—Davidson Baking Company, Portland, Ore.

Description—A white flour and whole wheat flour bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p. 817), prepared from patent flour, water, whole wheat flour, sucrose, molasses, shortening, yeast, salt, a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, a yeast food containing buttermilk, calcium phosphate and ammonium tartrate and malt syrup. The dough is twisted, which accounts for the name "Spun".

**STEUART'S GOLDEN CROWN BRAND CANE
SUGAR AND MAPLE SYRUP**

Manufacturer—Steuart, Son and Company, Baltimore.

Description—A table syrup, sucrose syrup flavored with pure maple syrup.

Manufacture—Cane sugar and maple syrups are mixed in definite proportions, heated to 101 C, adjusted to the desired density, filtered, and automatically canned.

DERMAL MANIFESTATIONS OF VITAMIN A DEFICIENCY

For the most part the dietary regimen of the average American family in ordinary times has become so nearly adequate under modern conditions of living that little consideration has been given to the possible existence of dietary deficiencies. It is of course, well known that in certain localities the deficiency disorder described as pellagra at times becomes prevalent and that rickets has by no means become eradicated. Scurvy no longer is prominent in the conventional lists of diseases in this country, and characteristic beriberi is practically unknown. Accordingly, physicians have for the most part remained somewhat indifferent to the problems of avitaminosis except when these have been presented in an unmistakable, outspoken manifestation. McLester¹ has well remarked, however, that the interest which vitamins hold for the physician is not alone in their relation to certain well defined diseases, such as scurvy, beriberi and rickets, but rather in the fact that chronic vitamin deficiency produces numerous vague borderline states of ill health which often puzzle the physician and disable the patient. These last are of far greater importance to the physician of today than the more clearly defined deficiency diseases.

The inference that avitaminosis may occur in some subacute form more frequently than is suspected presents a challenge to the physician to attempt to discover diagnostic symptoms before they become herculean in character. Unfortunately, the precise pathogenesis underlying the deficiency disorders still remains relatively obscure in many instances. The ignorance or, rather, the lack of knowledge in this field hampers progress and precludes early attempts at prophylaxis. In the case of vitamin A there has been a tendency fostered far more by manufacturers than by the medical profession, to attribute to it remedial or prophylactic virtues that are far from proved. This is particularly true of the claims for "anti-infective" potency based on rather uncertain or even contradictory evidence.

The subject was recently discussed in some detail in *THE JOURNAL*.²

The circumstance that some of the enthusiasm about the role of vitamin A (and probably this applies to other dietary essentials) has not been fully warranted by the facts of experimental investigation should not act to discourage further research. The opportunity to make contributions to existing knowledge of symptoms of latent avitaminosis lies in the grasp of the bedside practitioner quite as well as of the laboratory worker. An interesting illustration of this is afforded by the recent report of Loewenthal³ from Kampala, East Africa. It involves a new manifestation in the syndrome of vitamin A deficiency—a "pure cutaneous avitaminosis." The story, which is of unusual interest, deserves repetition here.

The discovery of this dermatosis was made at the quarterly inspection of the Uganda Central Prisons during which every prisoner stripped in order that his skin might be examined. It was struck by the number of men, many of them of middle age who presented the clinical picture of acne vulgaris combined with a dermatosis which none of the medical officers present could define. When Dr. H. B. Owen, who was examining the prisoners' eyes, segregated those suffering from night blindness and xerophthalmia, it was apparent that these men formed the bulk of those affected by the peculiar dermatosis. At subsequent monthly inspections of prisoners all new cases of this dermatosis were recorded and it was found that the majority of these men suffered from night blindness and xerophthalmia, while almost every sufferer from xerophthalmia and night blindness showed these cutaneous changes. Up to the present I have seen over 130 cases of this dermatosis.

The occurrence of dermatoses involving dryness of the skin, itching folliculitis and acneiform eruptions is not unusual. In the present instances, however, there was no pus formation. The condition was that of a dyskeratosis, with changes consequent on this condition and without signs of sepsis or softening. The principal involvement was of the cutaneous epithelium, a characteristic pathologic manifestation for other types of epithelium when vitamin A is lacking. This diagnostic interpretation is supported by the evident shortcomings of the prison diet, which consisted of maize, bean, dried meat, nuts, salt and sweet potatoes. Loewenthal reports that in other prisons where there is a great abundance of sweet potatoes in the diet, dry skins were common and scabies and other parasitic diseases were almost universal but that the dermatosis described was not seen in a single case. Further, a careful inspection of the prisoners' eyes was carried out, and no cases of xerophthalmia were noted, nor was night blindness complained of. Thus he avers, on an almost fat free dietary which is rich in vitamin A content a dry skin may occur, but the papulofollicular dermatosis is not seen. Added proof of the correctness of the diagnosis is found in the circumstance that, with the ration and routine otherwise unchanged, daily administration of an ounce of cod liver oil promptly remedied the night

blindness, xerophthalmia and dermatosis. Even concentrates were effective, thereby excluding fat as an explanation of the therapeutic success. The demonstration of true dermal manifestations of vitamin A deficiency relatively uncomplicated by other results of general undernourishment is thus doubtless somewhat unique.

THE ACID-BASE EQUILIBRIUM IN HEALTH

The French physiologist Charles Richet once remarked "The living being is stable. It must be in order not to be destroyed, dissolved or disintegrated by the colossal forces, often adverse, which surround it. By an apparent contradiction it maintains its stability only if it is excitable and capable of modifying itself according to external stimuli and adjusting its response to the stimulation. In a sense it is stable because it is modifiable—the slight instability is the necessary condition for the true stability of the organism." It is well to bear such paradoxical generalizations in mind whenever supposed menaces are pointed out as a possible marked change in the environment or dietary regimen. No one will gainsay that serious upsets may attend pathologic conditions, particularly when the regulatory functions are seriously impaired, but the normal tendency is invariably toward the preservation of "steady states" in the body.

Cannon¹ has pointed out that the coordinated physiologic reactions that maintain most of the steady states in the body are so complex and are so peculiar to the living organism that it has been suggested that a specific designation for these states be employed—homeostasis. In an open system, Cannon states, such as the body represents, compounded of unstable material and subjected continually to disturbing conditions, constancy is in itself evidence that agencies are acting, or ready to act, to maintain this constancy.

An illuminating example of the preservation of the "steady state" in the organism has recently been furnished by experiments on man at the Santa Barbara Cottage Hospital in California.² They relate to the difficulties in producing sustained changes in the carbon dioxide content and p_H of the blood plasma, outside the so-called normal limits, by exceptional changes in the diet. Of course, changes can be produced by sufficiently drastic measures. An acidosis can be produced by ingesting from 15 to 20 Gm of ammonium chloride. This will reduce the blood p_H by 0.2. The Santa Barbara biochemists found that the daily administration of 45 Gm of sodium bicarbonate was necessary to change the reaction of the blood to a similar extent in the opposite direction. Smaller amounts of these substances on administration will at most produce transitory effects. It would require 18 pounds (more than 8000 Gm) of oranges to have an alkaline ash content

equivalent to 40 Gm of sodium bicarbonate, and 4½ pounds (about 2,000 Gm) of lean beef or 2 pounds (900 Gm) of oysters to have an acid ash content equivalent to 15 Gm of ammonium chloride.

In the experiments at Santa Barbara, the daily administration of 30 Gm of sodium citrate was the smallest amount of alkali that produced a shift in the acid-base equilibrium of the blood drawn before breakfast, outside the normal variation of the individual but inside the normal variation of a normal group. There was no significant difference in the acid-base picture of the blood of a normal individual drawn before breakfast whether the mixed diet consumed contained excessively acid or excessively alkaline ash foods. The diet regularly consumed by the individual contained potentially as much acid ash as a diet planned to be excessively acid. A diet containing 240, 204 and 93 Gm of protein on consecutive days and 200 cc of normal acid equivalent of ash daily produced a doubtfully significant shift in the blood picture to the acid side. The ingestion of 1 quart of milk, 1 quart of orange juice or 1 pound of bananas produced no temporary shift in the plasma p_H or alkali reserve. The ingestion of 1 pound of steak temporarily lowered the plasma bicarbonate significantly in only one of four individuals studied. The absolute values were well within the group range. These are enormous adjustments, yet they seem to be readily made during health. They should serve to dispel much of the popular fear of "acidosis," which has been so widely encouraged in recent times by purveyors of supposed "corrective" foods.

CIGARET SMOKING AND THE BLOOD SUGAR

Undoubtedly tobacco stands next to alcohol and alcoholic beverages in the list of substances that have at times aroused not only vigorous but even violent debate regarding their proper place in the daily regimen of man. It would be easy to quote both encomiums and condemnations for the widespread habit of smoking. There comes to mind, on the one hand, the oft repeated verse beginning "Hail! Social Pipe—thou foe to care" and, on the other hand, the statement that in the seventeenth century, in Russia, smokers' noses were cut off.¹ The qualitative facts about tobacco—and particularly its smoke—are fairly well known. The combustion of the leaf, like that of other plants, produces certain volatile products, which may be drawn into the mouth from a pipe, cigar or cigaret. Tobacco, however, is unusual in yielding measurable quantities of the powerful alkaloid nicotine. This is an important distinction characteristic of tobacco. It is stated that, on heating, pyridine as well as other bases are formed, together with phenol, ammonia, methane, hydrocyanic acid, furfural and carbon monoxide.

² B. cheff, Fritz, Sanum W. D. Long M. Louisa and Dewar Margaret M. The Effect of Acid Ash and Alkaline Ash Foodstuffs on the Acid Base Equilibrium of Man. *J. Nutrition* 7:51 (Jan) 1934.

¹ Fisher Irving and Fisk E. L. How to Live ed 19 New York. Funk & Wagnalls Company 1932.

This sounds like a formidable list of menaces to human welfare. Physiologists have learned, however, that many substances enter the organism in minute quantities without producing detectable harm. Chemists have suggested that the carbon monoxide in tobacco smoke may be the cause of the ill effects, if not the pleasure, of smoking. The writers² who point this out reply that in fact a heavy smoker accumulates less carbon monoxide than does the nonsmoker who takes a walk on Fifth Avenue, New York, during the hours of heavy automobile traffic. The same writers add that other products of combustion, notably pyridine, have likewise been suggested but occur not only in tobacco smoke but also in the smoke from other vegetable matter, such as corn silk, maple leaves and coffee beans. That these substances do not contribute appreciably to the gratification of smoking is conclusively demonstrated by the fact that few smokers adhere to juvenile substitutes for tobacco. Such substitutes are cheap, yet tobacco maintains its popularity. Why tobacco?

A chance observation made by Haggard and Greenberg² in the Laboratory of Applied Physiology at Yale University affords a new suggestion. It was found that smoking produces a definite, although temporary, increase in the concentration of blood sugar, and a corresponding increase in the rate of sugar combustion in the body. These effects certainly are due to nicotine and arise from its action on the suprarenals. Haggard and Greenberg believe there can be little doubt that this is the source of at least a considerable part of the gratification from smoking.

The fact that nicotine affects the suprarenals is by no means new. It was clearly described by Cannon, Aub and Binger³ at the Harvard Medical School and referred to in *THE JOURNAL*⁴ more than twenty years ago. The novelty of the Yale experiments lies in the demonstration of effects from tobacco smoke. The results showed that, when the respiratory quotient is above 0.85 and the blood sugar correspondingly above 0.13 per cent, the smoking of a cigaret has no appreciable influence on either. When, however, the respiratory quotient and blood sugar have fallen below these values, and especially when the fasting level has been reached, the smoking of a cigaret is followed by a rise in both. Values are attained within fifteen minutes as high as 0.85 or 0.90 for the respiratory quotient and 0.12 or 0.14 per cent for the sugar. During the next thirty minutes the values fall gradually to, or slightly below, those observed before the cigaret was smoked.

Further inferences may be drawn from the facts now available. Fatigue and irritability are sometimes associated with a low or fasting level of the blood sugar. Perhaps smoking, by inducing a secretion of suprarenal medullary hormone, induces a hyperglycemia that tem-

porarily relieves the distress. Smoking is also alleged to relieve the symptoms of hunger—a phenomenon that attends a lowered content of dextrose in the circulating medium. Haggard and Greenberg allege that other effects of smoking, the acceleration of the pulse and the temporary rise in arterial pressure, are presumably, like the increase in sugar concentration, dependent on discharge of epinephrine. It is doubtless true that "the poetic effusions of the lovers of the weed are no safer guide than the exaggerated and intemperate pronouncements of people who have idiosyncrasies against tobacco and simply hate it." But the observations from the Yale laboratory may help to explain why tobacco rather than any other substance is used for smoking, the smoker obtains from tobacco repeated minute doses of nicotine.

Current Comment

THE ETIOLOGY OF AGRANULOCYTOSIS

Agranulocytosis is a clinical syndrome that has been frequently reported only within the last few years. Several theories have been suggested as the cause of this highly fatal disease, but a satisfactory explanation has not yet been offered. It is important to consider carefully all the evidence presented. Madison and Squier¹ in this issue of *THE JOURNAL* report fourteen cases of agranulocytosis in which a definite history was obtained in each case of the use of amidopyrine (in combination with a barbitol preparation, amidopyrine alone, or in one case in combination with other drugs) immediately prior to the clinical discovery of the disease. In treating these cases of agranulocytosis, the Milwaukee investigators endeavored to stimulate granulopoiesis in all of them by means of transfusions, nucleotide or yellow bone marrow extract. In eight cases the further use of amidopyrine was strictly prohibited. In the other six cases the use of amidopyrine was permitted for the relief of pain and restlessness, because its harmful effect was not fully appreciated. Among these six cases the mortality was 100 per cent, in spite of the fact that four of the patients recovered from the acute attack. Among the eight cases in which the use of these drugs was prohibited, only two deaths occurred, and in each of them the granulocytopenia was extreme at the time the diagnosis was made. To obtain further evidence of the ability of these drugs to depress the granulocytes, two patients who had recovered from the acute attack were given 0.3 Gm. of amidopyrine and 0.45 Gm. of amidopyrine together with 0.2 Gm. of amytal, respectively. Within a few hours both of these patients showed a temporary marked depression of the granulocytes. To obtain still further evidence, the authors gave eleven rabbits either allylisopropylbarbituric acid (alurate) with amidopyrine or amidopyrine alone. On the twenty-fifth day, one rabbit receiving an average of 1.3 Gm. of amidopyrine duly showed an abrupt drop in the granulocytes, which progressed until its death on the thirtieth day. Preceding its death this

¹ Madison F. W. and Squier T. L. The Etiology of Primary Granulocytopenia (Agranulocytic Angina) this issue p. 755.

rabbit showed a complete absence of granulocytes in the peripheral blood, and at necropsy the bone marrow was found to be absolutely lacking in the cells of the granular series. None of the other rabbits showed the blood picture of granulocytopenia. It is an extremely interesting fact that the period of rapid increase in the number of cases of agranulocytosis reported in the literature coincides almost exactly with the increase in the use of drugs containing a combination of amidopyrine with a barbitol compound. In view of their study, Madison and Squier believe that amidopyrine, either alone or together with a barbitol preparation, is capable of producing primary granulocytopenia in certain persons who are sensitive to the drug. Although of a far different nature, Gillespie's² report in the *Lancet* of February 17 on the alleged dangers of the barbitals again emphasizes the fact that a considerable number of fatalities have in some way been associated with such drugs as barbitol, allonal, pernoston, phenobarbitol, dial, and other proprietary brands of barbitol preparations. Nevertheless Gillespie makes the broad conclusion that there is no case on record up to the end of 1932 in which the barbitals, in either a single dose or repeated doses of therapeutic size, have caused death in the absence of complicating factors. His one "possible reservation" is to the observations of Watkins at the Mayo Clinic of thirty-two cases of agranulocytosis, in twenty-four of which either amidopyrine or a barbituric acid derivative had been given before the onset of the granulocytopenia. In an experimental study, Kracke³ reports that subcutaneous injections of benzene and olive oil in sufficiently small doses would result in the development of clinical agranulocytosis in rabbits; he did not succeed, however, in producing the disease in animals by the injection or the oral administration of amidopyrine. Madison and Squier's observations should inspire others to study carefully their cases of agranulocytosis with particular reference to their relation to the use of these drugs. Moreover, their work again shows that clinical observation at the bedside of patients is a fruitful field for research.

THE ABSORPTION OF CAROTENE

With the importance of the recognized vitamins as food factors clearly established by nutrition experiments, it has become eminently desirable to learn the details of their function. First comes the question of alimentary absorption. Some of the vitamins are water soluble, for them no serious problem of transfer from the gastro-intestinal canal to the blood stream arises. Other vitamins do not have a comparable solubility. This is notably true of vitamin A and its yellow pigment precursor, carotene. Dispersed in colloidal form in aqueous fluids, carotene does not penetrate ordinary biologic membranes. Furthermore, it does not occur in colloidal form in the blood. The explanation of absorption seems to have been provided in studies of von Euler and Klusmann⁴ in the biochemical institute at the

University of Stockholm. Like numerous other compounds that are insoluble in water but dissolve in certain organic solvents, carotene and other carotinoid pigments pass into aqueous solutions of the bile salts. This procedure has long been known as a possible mode of absorption of the water-insoluble fatty acids, which must often be liberated in considerable quantities in the course of the lipolytic digestion of fat in the intestine. It is conjectured that after absorption, carotene is again displaced from its association with the bile salts. The details are still lacking. The salient facts are obviously of fundamental importance.

Association News

MEDICAL BROADCASTS Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, Central standard time. The next three broadcasts will be as follows:

- March 15 The Health of the School Child W. W. Bauer, M.D.
- March 22 Progress of Surgery Morris Fishbein, M.D.
- March 29 Flowers That Bloom in the Spring, W. W. Bauer, M.D.

National Broadcasting System

The Association broadcasts on a coast-to-coast network each Monday afternoon from 4 to 4:15, Central standard time (5 o'clock, Eastern standard time, 3 o'clock, Mountain standard time, and 2 o'clock, Pacific standard time). The next three broadcasts will be as follows:

- March 12 Low Blood Pressure R. G. Leland, M.D.
- March 19 Mechanization of Medicine Morris Fishbein, M.D.
- March 26 Why Pasteurize? W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Personal—Dr. William A. Stanley, acting health officer of Blount County, has been appointed in charge of the Bullock County Health Department; he will be succeeded in Blount County by Dr. Samuel D. Sturkie, Jr., Collinsville. Dr. Cline V. Hendrix, Oneonta, recently resigned the latter post to return to private practice.—Dr. Arthur M. Shelamer, Union Springs, has been named health officer for Colbert County.

CALIFORNIA

Society News—The Solano County Medical Society, Vallejo, was addressed, February 13, by Drs. Leo P. Bell and Donald McNeil, Sacramento, on "Lesions of Stomach and Duodenum" and "Gas Gangrene," respectively.—The Pacific Physical Therapy Association was addressed, February 21, by Drs. George K. Abbott, Glendale, and Walter A. Hodges, Pasadena, on "Surgical Aspects of Physical Medicine" and "Sanatorium Treatment of Tuberculosis," respectively.

Course for Health Officers—The University of California will offer a twelve weeks course of training for health officers, May 14 to August 3. The first six weeks study in Berkeley, under the direction of Dr. Frank L. Kelly, will consist of class instruction, group discussions and field demonstrations. The next four weeks will be spent in the San Joaquin County Health Unit, where students will receive field experience under the supervision of Dr. John J. Sippy. In the last two weeks each student will be required to make a survey of the health work in a community near enough to Berkeley so that frequent conferences can be held with faculty members. The course will

² Gillespie, R. D. On the Alleged Dangers of the Barbiturates. *Lancet* 1:11 (Feb. 17) 1934.

³ Kracke, R. K. The Experimental Production of Agranulocytosis. *Am. J. Clin. Path.* 2:11 (Jan.) 1932.

⁴ von Euler, H. and Klusmann, Erika. Zur Biochemie der Carotinoide und des Vitamins C (Ascorbinsäure). *Ztschr. f. physiol. Chem.* 219:215 (Aug.) 1933.

not carry university credit, but a certificate of attendance will be issued to those completing it satisfactorily. The regular fees of the intercession and summer session of \$35 will be charged, no laboratory fees will be charged. Applications should be sent to the chairman, department of hygiene, University of California, Berkeley, and should be accompanied by a statement of professional training and experience.

CONNECTICUT

Yale Building Program Completed—Construction work at Yale University School of Medicine, in progress almost continuously for the last five years, has been temporarily completed. In the Sterling Hall of Medicine are the laboratories of anatomy, physiology, physiologic chemistry, pharmacology and psychobiology. The Institute of Human Relations contains the laboratories and clinical facilities of the department of psychiatry and mental hygiene, the laboratories of psychology and physiologic psychology, the laboratories of the clinic of child development, and the quarters of the anthropology division and of research in the social sciences. The Sterling Hall of Medicine also contains the library, amphitheater, administrative offices and recreational facilities of the school of medicine. On the west side of Cedar Street are the buildings of the New Haven Hospital and the clinical divisions of the school of medicine. The Clinic Building constitutes the center of this group. Two new pavilions, Raleigh Pitkin Memorial for medicine and pediatrics, and the Sarah Wey Tompkins Memo-

Court between Institute of Human Relations and Sterling Hall of Medicine

rial for surgery and obstetrics, are both six story buildings, each with five ward floors. The Farnam Memorial Building and the Medicine and Pediatrics Laboratory building have amphitheatres for teaching purposes. The departments of bacteriology, pathology and public health occupy the Brady Memorial Laboratory and Lauder Hall. The buildings are all of simple design and construction, on a unit basis with all units interconnecting and with a minimum amount of fixed equipment. The total cost of the modern buildings in the school and hospital group was about \$12,000,000, including equipment. The building expansion program of the school was formulated in 1920. The Sterling Hall of Medicine and the Private Pavilion were erected in 1923, and the other units have been added since 1928. The total capacity of the hospital, including nursery beds, is about 550.

GEORGIA

District Meeting—The Fifth District Medical Society will convene at the Academy of Medicine in Atlanta, March 22. The program will be presented by the following, among others:

Dr. Edgar G. Billenger, Atlanta: Relationship of Health Preservation to Genito-Urinary Symptoms.
Dr. Louis C. Roughlin, Atlanta: Nasal Accessory Sinuses as Foci of Infection.

Dr. Clifford G. Grulee, Chicago: Breast Feeding and Infection—A Review of Twenty Thousand Cases.
Dr. Barney Brooks, Nashville, Tenn.: Influence of Simultaneous Ligation of the Veins on the Incidence of Gangrene Following Arterial Obstruction.

Dr. Marion C. Pruitt, president, Fulton County Medical Society, will give the address of welcome and Dr. Charles H. Richardson, Macon, president of the Medical Association of Georgia, the response. A luncheon will be given by the Academy of Pediatrics in honor of Dr. Grulee.

ILLINOIS

Research on Amebic Dysentery—With the objective of perfecting a blood test for the diagnosis of amebic dysentery, the state department of public health is asking physicians to submit blood specimens of patients with this disease. These analyses are being made in the Chicago branch of the state diagnostic laboratories at 1819 West Polk Street. Dr. Lloyd L. Arnold, head of the branch laboratory and professor of bacteriology and preventive medicine at the University of Illinois College of Medicine, is in charge of the work. He is assisted by Dr. Emil Weiss.

Society News—Dr. Charles A. Aldrich, Chicago, spoke before the Will-Grundy County Medical Society, February 21, on "Nephritis in Children."—At a meeting of the St. Bernard Research Society, February 13, Dr. Bernard Portis, Chicago, talked on "The Surgical Treatment of Duodenal Ileus."—Dr. Rollo K. Packard, Chicago, discussed medical economics before the Fulton County Medical Society, February 21.—Dr. Max Thorek, Chicago, spoke before the Kankakee County Medical Society, February 8, on "Treatment of Carcinoma of the Rectum by Electrosurgery."—The St. Clair County Medical Society was addressed, February 1, by Dr. William C. Stude, St. Louis, on obstetrics with special reference to pelvic measurements.—At a meeting of the Adams County Medical Society in Quincy, February 12, Dr. Rosco G. Lehn, Chicago, discussed "The Economics of Medical Practice."—Dr. Lewis J. Pollock, Chicago, spoke on "Organic Spinal Cord Diseases" before the Peoria City Medical Society, February 6. Dr. Max Cutler, Chicago, addressed the society, February 20, on "Medications, Limitations and Advances in the Radium Treatment of Cancer."—Dr. Scott J. Wilkinson, Decatur, addressed the Christian County Medical Society January 7, on "Emergencies in Pediatric Practice."

Chicago

Contagious Disease in Private Practice—The Chicago Medical Society will hear a discussion of "Contagious Disease in Private Practice," March 14, at the Medical and Dental Arts Building. Dr. John J. McShane of the state department of health, Springfield, will speak on "Seasonal Aspects and Modes of Transmission of Common Contagious Diseases in Illinois," and Dr. Archibald L. Hovne, medical superintendent, Municipal Contagious Disease Hospital, "The Important Considerations Regarding Contagious Disease in Chicago."

The Names of Medicines in Motion Pictures—The part that motion picture organizations take occasionally in presenting to the public the names of medical substances with indications for their use was viewed with disfavor in a resolution adopted by the Chicago Medical Society, February 13. Recognizing that such recommendations are unwise on the part of men untrained in pharmacy, impolitic on the part of the manufacturers and a potential source of public danger, and that to conserve the public health the prescription of remedies for illness should be restricted to the medical profession, the council of the society has requested Will H. Hays, director of the moving picture industry, to forbid the practice.

Society News—At a meeting of the Chicago Surgical Society, March 2, the speakers included Drs. James K. Stack on "Prognosis in Fractures of the Carpal Scaphoid," and John L. Yates and Silvanus A. Morton, Milwaukee, on "Operative Correction of Diaphragmatic Hernia, Postoperative Care of the Patient."—The Chicago Council of Medical Women was addressed, March 2, by Drs. Alice McNeal and Nora F. B. Brandenburg on "Pentobarbital Anesthesia" and "Bronchoscopy," respectively.—Speakers before the Chicago Laryngological and Otolological Society, March 5, were members of Northwestern University Medical School, among others, Drs. John F. Delph and Max T. Lampert spoke on "Endoscopic Experience" and "Combined Laryngofissure for Cancer of the Larynx," respectively.

KENTUCKY

Bills Passed—H. 662 has passed the house, proposing to repeal the laws regulating the possession and sale of narcotic drugs and to enact the uniform narcotic drug act. H. 318 has passed the house and the senate, proposing to discontinue the registration of assistant pharmacists. Assistant pharmacists who are now registered may be, until October 1938, examined for registration as pharmacists. S. 151 has passed the senate and the house, proposing to abolish the office of state supervisor of chiropractors. H. 388 has passed the house, proposing to forbid the possession or sale of marihuana except on the prescription of a licensed physician.

Bills Introduced—S 278 proposes to make the records of any public hospital admissible in evidence and prima facie proof of the statements made therein without the personal testimony of the persons making the records. S 303 proposes to repeal the laws relating to narcotics and to enact the uniform narcotic drug act. S 341 proposes to authorize the sexual sterilization of insane, feeble-minded or epileptic inmates of state institutions and of habitual criminals. S 352 proposes that in the distribution of the assets of an insolvent decedent's estate the hospital bills and the doctors' bills incurred in the last illness have an equal priority with burial expenses and costs of administration and that until these charges have been met no other claims may share in the assets. S 353 proposes to accord to hospitals treating persons injured through the negligence of other persons liens up to \$200 on any rights of action, claims, judgments or settlements accruing to such injured persons by reason of their injuries. This lien, however, is not to attach to any recoveries had under the workmen's compensation act.

MARYLAND

Thayer Lectures—Dr James B. Murphy of the Rockefeller Institute for Medical Research delivered the William Sydney Thayer and Susan Read Thayer Lectures in Clinical Medicine, March 8-9, in the Hurd Memorial Hall of Johns Hopkins Hospital. "Four Important Phases of Cancer Research" and "Avian Tumors in Relation to the General Problem of Malignancy" were the individual titles of Dr. Murphy's discussion of the "Experimental Approach to the Cancer Problem."

Health Conditions in 1933—Fewer deaths in the state from all causes (20,596) in proportion to the population than at any time since these records have been kept in the state were noted for Maryland in 1933. There were 27,633 births reported during the year in comparison with 28,740 in 1932, but there were fewer deaths among infants under 1 year old, in proportion to the number of births, than at any time since the state has been keeping records of births and deaths. Of the total deaths, 3,707 were of persons under 25 years of age, 2,872 between 25 and 44, and 14,017, or more than two thirds of the total, more than 45 years of age. Diseases of the heart were responsible for 4,324 deaths, diseases of the kidneys for 2,439, cancer for 2,005, cerebral hemorrhage for 1,607 and diabetes for 398.

MASSACHUSETTS

Dr Landsteiner Gives Cutter Lecture—Dr Karl Landsteiner of the Rockefeller Institute for Medical Research, New York, will deliver the Cutter Lecture on Preventive Medicine at Harvard Medical School March 16. He will speak on "Immunochemical Specificity."

Clinical Meeting—Dr E. Starr Judd, professor of surgery, University of Minnesota Graduate School of Medicine, will conduct a clinic at the Boston City Hospital, April 16, under the auspices of the department of surgery, Boston University School of Medicine. His subject will be "Surgical Diseases of the Biliary Tract." Taking part in the discussion will be Drs. Horace Binney, Arthur W. Allen and Elliott C. Cutler.

Society News—Richard K. Conant, commissioner of public welfare of Massachusetts discussed "The Doctor and the Departments of Public Welfare" before the Essex North District Medical Society, January 3, among others. Dr. John B. Hayes II has been elected president of the Boston Tuberculosis Association. Dr. Clarence O. Cheney, New York, addressed the Massachusetts Psychiatric Society, February 23, on "Some Activities of the New York Psychiatric Institute and Hospital."

MICHIGAN

Society News—Speakers participating in a program on recent advances in medicine and surgery before the West Side Medical Society, Detroit, March 1, were Drs. Clarence Baker, Louis J. Bailey, Clarence E. Uniphrey, John B. Rieger, David I. Sugar and Samuel A. Flaherty. Dr. Morris Fishbein, Chicago, editor of THE JOURNAL, addressed the Wayne County Medical Society in Detroit, March 5, on "The Doctor and the State."

Bill Passed—S 8-XX has passed the Senate proposing to amend the pharmacy practice act by providing that the members of the board of pharmacy shall receive \$10 for every day actually engaged in the work of the board and their necessary traveling expenses. Under the present law the members of the board serve without compensation but their traveling and other necessary expenses incurred in the performance of their official duties are refunded.

MINNESOTA

Survey of Nutrition of Children—That malnutrition is not a factor in the health of school children of Minneapolis is evidenced in the report of a recent survey of 100 schools. Seventy-seven schools reported absence of noticeable malnutrition, with an occasional case of undernourishment peculiar to the home and family rather than to the economic situation. Fourteen schools reported a noticeable improvement in the nutrition status of the children as compared with the surveys of a year and two years ago. In these schools particular attention is called to the fact that a fair, if not large, percentage of the students come from homes receiving public relief and attribute the favorable conditions to the fact of better food selection.

MISSISSIPPI

Bill Enacted—H 95 has been approved by the governor, amending the law forbidding the sale, barter or giving away of cannabis indica or of commodities intended for smoking which contain cannabis indica, so as (1) to forbid also the keeping or possessing of such commodities, and (2) to permit sale and/or possession on the prescription of a physician.

Societies Merge—The consolidation of the Clarksdale and Six Counties Medical Society and the Delta Medical Society was approved at a meeting of representative committees in Rosedale, December 7, the new organization to be known as the Delta Medical Society. All counties in the delta are encompassed in the two societies, with the exception of Sharkey and Issaquena. It was agreed to hold three meetings a year, at Clarksdale, Greenville and Greenwood in rotation. The Clarksdale and Six Counties Medical Society has already voted for the union, and the Delta Medical Society is expected to act at its April meeting in Cleveland. The new society will probably seek a charter at the May meeting of the house of delegates of the state medical association.

MISSOURI

Mask of John Hunter—A replica of the death mask of John Hunter was presented to St. Louis University School of Medicine, St. Louis, January 11, by Dr. William W. Graves, director of the department of neuropsychiatry. Dr. Graves acquired the mask in 1924, while working in the Hunterian Museum of the Royal College of Surgeons in England. It will probably be placed in the library of the school.

Society News—Dr. Ralph S. Muckenfuss, St. Louis, addressed the Kansas City Academy of Medicine, February 16, on "Practical Clinical and Therapeutic Problems as Related to the Study of Virus Disease."—A symposium on pneumonia constituted the program before the St. Louis Medical Society, February 20, the speakers were Drs. Anthony B. Day, Harry L. Alexander and Edward Lawrence Keyes III. In addition, Henry T. Scott, Ph.D., director of biologic research, Wisconsin University Alumni Research Foundation, Madison, discussed "Irradiated Vitamin D Milk."—Dr. Sidney I. Schwab addressed the St. Louis Neuropsychiatric Society, February 26, on "The Utilization of Freudian Concepts in Neurology and Psychiatry—An Illustrative Case and Episodes."—A joint meeting of the St. Louis Pediatric Society and the Orthopedic Surgeons of St. Louis, February 23, was addressed by Drs. Hugh McCulloch on "Children's Feet and Shoes," James Archer O'Reilly "Posture," Charles A. Stone, "Early Treatment of Poliomyelitis," and Theodore C. Hempelmann, "What Can be Done for Cerebral Palsies."—At a meeting of the Jackson County Medical Society, February 20, speakers were Drs. Carl F. Nelson, Lawrence, Kan., and Charles J. Eldridge, Kansas City, on "Hemoglobin, Its Chemistry, Standard and Clinical Significance" and "Intussusception," respectively.

NEW HAMPSHIRE

Acting Secretary Designated—Dr. Carleton R. Metcalf, Concord, has been designated secretary pro tempore of the New Hampshire Medical Society to act until the next session of the society in May, to take the place of the late Dr. Dennis E. Sullivan.

NEW JERSEY

Bills Passed—The following bills have passed the assembly. A 4, proposing to require a thorough physical examination, including, if necessary, a "stereoscopic x-ray photograph" of the chest, of all students admitted to the state normal schools and teachers colleges, and of persons applying for certificates to teach in the public schools. and A 132, proposing that nothing in the state emergency relief act shall be

construed to prohibit or limit any licensed physician, occupying a position as a state, county, municipal or school physician from being compensated by the state for the care and treatment of emergency relief patients. S 94 has passed the senate, proposing to amend the law providing liens in certain cases for hospitals by raising to 50 cents the fee required to be paid on filing a claim of lien.

Bills Introduced—S 158 and A 314, to amend the workmen's compensation act, propose to make compensable pneumoconiosis contracted in any employment covered by the act. S 162 proposes to authorize the sexual sterilization of "a defective person likely, if not sexually sterilized, to procreate like defective persons," whether an inmate of a state institution or not. S 183, to supplement the medical practice act, proposes to make it a misdemeanor for any one other than a person licensed to practice medicine and surgery to "use in connection with his name the words or letters, 'doctor,' 'Dr,' 'physician,' 'surgeon,' 'M.D.,' 'M.B.,' 'specialist,' 'professor,'" S 184, to amend the workmen's compensation act, proposes to include silicosis as a compensable occupational disease, provided the disability commences within two years after the termination of such exposure. A 201 proposes to accord to physicians treating persons injured through the negligence of other persons liens on any causes of action, claims, judgments, settlements or compromises accruing to such injured persons because of their injuries. A 245, to amend the dental practice act, proposes, among other things, to add to the grounds on which a license to practice dentistry may be revoked a violation of any of the rules or regulations which the state board of registration and examination in dentistry may hereafter adopt with respect to the practice of dentistry. A 255 proposes to provide a fund whereby the state department of health may care for, treat or isolate human carriers of typhoid fever and other infectious and contagious diseases. A 262, to supplement the pharmacy practice act, proposes to require the annual registration of pharmacies and the payment of an annual fee of \$3. A 332, to amend the chiropody practice act, proposes to define chiropody as "the examination, diagnosis or treatment of any ailment of the human foot, by minor surgical local medical (including the use of local anesthetics), mechanical or physical means." "Physical means shall be interpreted to be the use of light, heat, air, water and exercise, but shall not include the use of electricity except as applied to ailments of the human foot." A 339, to amend the nursing practice act, proposes to stagger the terms of members of the board of nurses' examiners. A 303 proposes to create a State Board of Osteopathic, Chiropractic and Naturopathic Examiners to consist of three osteopaths, three chiropractors and one naturopath and to regulate the practice of osteopathy, osteopathy and surgery, chiropractic and naturopathy. Osteopaths licensed under the provisions of this bill would be entitled to practice osteopathy in all its branches as taught and practiced in the legally incorporated schools or colleges of osteopathy, including, apparently, physical therapy, but could not legally prescribe or administer drugs. After 1940, apparently, osteopathic licensees would also be entitled to practice surgery. The bill proposes to define chiropractic as the "diagnosis and treatment of disease by the adjusting by hand only of the vertebral column and tissues." Such a license would not permit a chiropractor to prescribe drugs, practice obstetrics or perform any surgery requiring cutting. The bill defines naturopathy as the "diagnosis and treatment of disease by the use and prescription of use of the following psychological, mechanical and material therapies: psychotherapy, mechanotherapy, physiotherapy, pneumotherapy, phytotherapy, electrotherapy, geo-therapy, hydrotherapy, corrective orthopedics and dietetics."

NEW YORK

Bill Passed—S 297 has passed the senate, proposing to permit any corporation organized under the membership corporations law of the state to establish, maintain and operate subject to the approval of the superintendent of insurance, a nonprofit plan to provide hospital care to its members.

Bill Enacted—S 155, permitting the board of regents to restore a license to practice medicine to a person whose license has been forfeited by conviction of any felony, if such person is pardoned by the governor of the state or by the President of the United States of the felony of which he was convicted, has been enacted as chapter 26, Laws, 1934.

Bills Introduced—S 690, to amend the nursing practice act, proposes to require applicants for licenses to practice nursing to be citizens of the United States. This provision, however, is not to apply to nurses who give their services free of charge through a charitable and/or religious agency. S 890

proposes that whenever expert evidence is necessary in any trial the court may, on its motion or on the motion of either party, appoint one or more experts to investigate and to testify at the trial. The court is to fix the compensation of such experts and may at any time before or during the trial limit the number of expert witnesses to be called by any party. S 926 proposes that no corporation shall hereafter be permitted to do business in the state if the word "Doctor" or "Dr" is a part of its corporate name.

New York City

Disease Among Mendicants—Among 370 mendicants arrested from January 2 to 24 in an effort to end street begging, 150 were found to be suffering from disease, according to a report of the Welfare Council, which sponsored the project in cooperation with the magistrates' courts. Forty of the men had acute venereal diseases, 110 were chronic alcoholics, 25 were chronic narcotic addicts and others were more recently addicted to drugs. Sentence was suspended in 200 cases, these men being directed to institutions where their needs could be cared for. Those suffering from active diseases and chronic alcoholism were given indeterminate sentences in order that they might receive treatment. The presence of these diseased persons on the streets was called a serious public health menace.

Spring Lectures—The spring series of Friday afternoon lectures sponsored by the Medical Society of the County of Kings in its auditorium in Brooklyn was opened by Dr. John B. D'Albora, February 23, speaking on "Colitis—Its Causes and Management." Dr. Edwin P. Maynard, Jr. delivered the second lecture, March 2, on "Management of the Medical Aspects of the Emergencies of Pregnancy," and Dr. Irwin E. Siris, the third, March 9, on "Common Fractures of Childhood." The remainder of the series includes the following:

March 16 Dr. Tasker Howard: Coronary Occlusion.
March 23, Dr. Fedor L. Senger: Endoscopic Resection of Bladder Neck Obstruction.
April 6 Dr. Robert F. Barber: Injection Treatment of Varicose Vein.
April 13 Dr. Harold R. Merwarth: Pain in the Head and Face.
April 20 Dr. Emil Goetsch: Medical and Surgical Aspects of the Gout Problem.
April 27 Dr. George I. Swetlow: Role of the Physician in the Court room in Problems of Exaggeration, Neurosis and Malingering.
May 4 Dr. Thurman B. Givan: Syphilis in Childhood.

Hospital News—Among special lecturers at the New York Polyclinic Medical School and Hospital recently were Drs. Frank H. Lehey, Boston, who gave an address, January 8, on "Esophageal Diverticulum: Its Diagnosis, Surgical Management and End Results," Irving W. Potter, Buffalo, January 20, "The Technique of Version," and Murray B. Gordon, clinical professor of pediatrics, Long Island College of Medicine, "Diagnosis and Treatment of Endocrine Conditions in Infants and Children."—The National Hospital for Speech Disorders has recently moved into new quarters at 126 East Thirtieth Street. The scope of its work, which has heretofore been confined mainly to pathologic conditions affecting speech, will now be broadened to include training in speech for normal persons, according to an announcement. In its sixteen years of existence the hospital has treated more than 30,000 persons. Dr. James Sonnett Greene is medical director.—For the first time in fifty years, St. Mary's Hospital was unable to meet its payroll February 1, covering the wages and salaries of about 300 employees, according to the United Hospital Fund. The hospital's difficulties are said to be further complicated by delay in payment by the city for public charges cared for in the institution. St. Mary's is a general hospital with about 330 beds. Last year 25 per cent of its ward services and 26 per cent of the outpatient services were given free to needy patients.

OHIO

Cleveland's Healthiest Year—The general death rate for Cleveland for 1933 was the lowest in the city's history, 9.7. The infant mortality rate, 45, was also the lowest ever recorded. For twenty-seven consecutive months the city has not had a case of smallpox, the health department reported. The tuberculosis mortality rate has been reduced 37 per cent in the past two years.

Resignation of Dr. Patten—Bradley M. Patten, Ph.D., associate professor of histology and embryology, Western Reserve University School of Medicine, Cleveland, has resigned to become assistant director for medical sciences of the Rockefeller Foundation, New York. Dr. Patten was educated at Dartmouth College and Harvard University and began his connection with Western Reserve in 1914. His research has dealt principally with the development of the heart and vascular system. He is the author of "Embryology of the Pig" and "Early Embryology of the Chick."

Personal—Dr Nathan Wallace Abbott, Cincinnati, observed his eightieth birthday January 31, he has occupied the same office for fifty-five years—Drs Gabriel B Kramer and David H Smeltzer, Youngstown, have recently been admitted to the bar—Dr Samuel E McMaster, Akron, was guest of honor at a dinner recently given by the staff of the People's Hospital on the occasion of his retirement from the consulting staff—Dr Louis Howard Schriver has recently been elected president of the Public Health Federation of Cincinnati—Dr Edgar L Vermilya, Fremont, was recently appointed health officer of the town for the twenty-fifth year—Dr John Dudley Dunham, Columbus, was elected chief of general staff of Grant Hospital, January 17—Dr Charles B Finebrock, Port Clinton, was recently elected president of the Northwestern Ohio Health Commissioners' Association

OREGON

University News—The alumni association of the University of Oregon Medical School will sponsor three days of clinics and lectures at the university in Portland, March 12-14. The guest speaker will be Dr Leo Eloesser, San Francisco, who will discuss surgical treatment in pulmonary tuberculosis and in certain forms of cancer

Society News—Dr Harry V Wurdemann, Seattle, addressed the Portland Academy of Ophthalmology and Otolaryngology, January 16 on "Traumatic Neurosis Following Accidents Affecting the Eyes and Vision"—Dr Winfred H Bueermann, Portland, addressed the Central Willamette Medical Society, Albany, January 5, on chronic appendicitis

PENNSYLVANIA

Graduate Courses in Pittsburgh—The Allegheny County Medical Society opened its seventh series of graduate courses for practitioners, March 1. They are being given at the University of Pittsburgh School of Medicine and at various hospitals. Duration of the courses varies from four to ten sessions. Subjects include cardiovascular and renal diseases, applied biochemistry, periodic health examination, elements of neurology, office gynecology, common ear, nose and throat conditions, and gross pathology

Physicians Address Social Welfare Conference—At a meeting of the Pennsylvania Conference on Social Welfare in Lancaster, February 21-24, speakers included Drs Harold A Miller, Pittsburgh, state director of medical relief, on "Supervision of the Sick", Donald Guthrie, Sayre, president, Medical Society of the State of Pennsylvania, "The Medical Profession Plans for Protection," and Samuel McC Hamill, Philadelphia, chairman, state emergency child health committee, "A Child Health Emergency Exists"

Philadelphia

Hospital News—Dr Edward W Beach has been appointed chief of the department of anesthesia at Wills Hospital. He is professor of anesthesia in the University of Pennsylvania School of Medicine and chief of the department at the Graduate Hospital

University News—Dr Chevalier Jackson has been appointed professor of bronchoscopy at the Woman's Medical College of Pennsylvania in charge of a new bronchoscopic clinic. Dr Emily Lois Van Loon, professor of otolaryngology, has been appointed clinical professor of bronchoscopy and will be associated with Dr Jackson in the conduct of the clinic. Dr Hans Ritter von Baeyer, formerly professor of orthopedic surgery at the University of Heidelberg, Germany, has accepted an appointment as lecturer at the college

RHODE ISLAND

Society News—Drs Herrmann L Blumgart and David D Berlin, Boston, addressed the Providence Medical Association February 5, on medical and surgical aspects, respectively, of "Treatment of Angina Pectoris and Congestive Heart Failure by Complete Ablation of the Thyroid." A symposium on tuberculosis was presented before the association, March 5, by Drs Ubaldio L Zambarrano and James Murray Beardsley, Providence and Robert Glen Urquhart of the Norwich (Conn) State Tuberculosis Sanatorium—Dr Lauretta Bender, New York, spoke on Alcoholic Encephalopathy at the State Hospital for Mental Diseases, Howard, February 26

SOUTH CAROLINA

Bill Passed—H 1309 has passed the house proposing to create a board of co-metic art examiners and to regulate the practice of hairdressing and cosmetology

TEXAS

Health at El Paso—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended February 24, indicate that the highest mortality rate (23.4) appears for El Paso, and for the group of cities as a whole, 12.7. The mortality rate for El Paso for the corresponding period last year was 15.3 and for the group of cities 12.3. The annual rate for eighty-six cities for the eight weeks of 1934 was 12.6, and the same rate appears for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate

VIRGINIA

Bill Passed—H 94 has passed both the house and the senate, proposing to repeal the laws relating to narcotic drugs and to enact the uniform narcotic drug act

Bills Introduced—S 325 proposes that the state commissioner of health shall be an ex officio member of the general board of directors of the state hospital for the insane and the state colony for epileptics and feebleminded at Madison Heights. A bill introduced in the House of Delegates by Mr Bandy February 16, and referred to the committee on general laws proposes to create in the state health department a division of barber examiners and to regulate the practice of barbering

Society News—Dr James Warren Sayre, Newport News, addressed the Warwick County Medical Society in Newport News, January 15, on acute appendicitis in childhood—Dr James Edwin Wood, Jr, University, addressed the Lynchburg Academy of Medicine, January 8, on "Emergencies and Pseudo-Emergencies in Heart Disease"—At a meeting of the Roanoke Academy of Medicine, January 8, speakers were Drs John H Neff and Harvey E Jordan, University, on "Renal Tumors" and "Extramedullary Blood Formation," respectively—Dr Everett C Drash, University, spoke on "Intrathoracic Neoplasms" before the Rockingham County Medical Society, Harrisonburg, January 8

WEST VIRGINIA

Bill Introduced—H 348-XX proposes to impose on every practitioner of medicine an annual occupational tax of \$25

Personal—Dr John F Cadden, formerly health officer of Boone County was appointed director of the division of vital statistics in the state department of health, February 1, succeeding Dr Carl F Raver—Dr Albert H Hoge Bluefield, was elected president of the West Virginia Public Health Council at a meeting, November 16

GENERAL

Neuropathologists Organize—The first meeting of the American Association of Neuropathologists was held in New York, Dec 28, 1933, and the following officers were elected: Drs George B Hassin, Chicago, president, Wilder G Penfield, Montreal, vice president, and Armando Ferraro, secretary. This society, which was organized in May, 1933, in Washington, D C, has for its object the advancement of the science of neuropathology, which is defined as including, first, investigation of the pathologic conditions spontaneously arising in the human or animal nervous system and experimental investigation of pathology, including pathologic anatomy involving the nervous system. Meetings will be held at the same time and place as the annual sessions of the American Neurological Association

Requests for Grants by Ella Sachs Plotz Foundation—Twenty-one grants were made by the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation during 1933, according to its tenth annual report. During the year 136 applications for grants were received, sixty-two of which came from thirteen different countries in Europe and Asia, the other seventy-four from the United States. Twelve of the new grants were made to scientists outside the United States. On account of economic conditions and the fact that many worthy scientists are without positions at present, about one third of the money appropriated was kept in reserve to aid these men. During the present great need of funds, the foundation has deviated from its policy of favoring researches on a single problem or closely allied problems and has given consideration to sciences closely related to medicine without

reference to special fields. Applications for grants to be held during the year 1934-1935 must be in the hands of the executive committee before May 1, 1934, and must state definitely the qualifications of the investigator, the character of the proposed research, the size of grant requested and the specific use of the money to be expended. These should be sent to Dr Joseph C Aub, Collis P Huntington Memorial Hospital, 695 Huntington Avenue, Boston.

News of Epidemics—Outbreaks of measles have recently been reported in newspapers from various parts of the country. In Philadelphia, the health department reported 3,079 cases for the first five weeks of 1934, compared with 144 cases for the same period of 1933. In Newburyport, Mass., 275 cases were reported during the week ended February 3, in Fargo, N. D., 495 cases between the early part of December and February 4, school attendance was seriously affected by a measles epidemic in Canadian County, Okla., centering in El Reno, Brookings, S. D., reported 50 cases in ten days preceding January 18, quarantine restrictions were applied in several sections of Norfolk County, Va., in January because of the prevalence of the infection. Forty-six states reported a total of 22,494 cases to the U. S. Public Health Service for the week ended, February 10, compared with 9,651 for the corresponding week of 1933.

—An outbreak of thirteen cases of typhoid in the Dunmore section of Scranton, Pa., in December was traced to impure raw milk sold by an unlicensed dealer. Another outbreak occurred in Bedford County, Pa., involving seven persons with one death, this was traced to an unguarded well in Riddlesburg. Schools were closed and serum was administered to all students. Forty-seven states reported 169 cases to the U. S. Public Health Service for the week ended February 10.

Society News—The Federation of American Societies for Experimental Biology will meet in New York, March 28-31. Sessions will be held in the Hotel Pennsylvania and demonstrations at Columbia University College of Physicians and Surgeons. The federation includes the American Physiological Society, American Society of Biological Chemists, American Society for Pharmacology and Experimental Therapeutics and American Society for Experimental Pathology. —Dr Paul V. Anderson, Richmond, was elected president of the Tri-State Medical Association of the Carolinas and Virginia at the annual meeting in Charlottesville, February 14 and Dr James M. Northington, Charlotte, N. C. reelected secretary. The 1935 session will be held in Charlotte. —The Catholic Hospital Association of the United States and Canada will hold its nineteenth annual convention in the Cleveland Public Auditorium, Cleveland, June 18-22. —Dr Francis E. Fronczak, Buffalo, was recently chosen president of the International Society of Medical Health Officers. —Dr George S. Stevenson, New York, was elected president of the American Orthopsychiatric Association at the annual convention in Chicago, February 24. Next year's meeting will be in New York, February 21-23. —The thirty-eighth annual convention of the National Congress of Parents and Teachers will be held in Des Moines, Iowa, May 13-19. The subject of discussion will be "The Future of the Forgotten Child."

Northwest Regional Conference—An informal discussion at breakfast opened the annual meeting of the Northwest Regional Conference at the Lowry Hotel, St. Paul, February 25, with Dr Benjamin F. Bailey, Lincoln, Neb., president in the chair. The following program was presented:

Interstate Radio Broadcasting Health Programs and State Office Organization Dr Edward A. Meyerding, secretary, Minnesota State Medical Association, St. Paul.
Public Health Education by the Doctor Dr William W. Bauer, director of the Bureau of Health and Public Instruction, American Medical Association, Chicago.
County Medical Societies Can Conduct Their Own Clinics Dr Philip H. Kreuscher, president, Illinois State Medical Society, Chicago.
Common Abuses in Committing Mental Cases to State Hospitals Dr William H. Hengstler, St. Paul.
Medical Care of the Indigent in Wisconsin Mr J. George Crownhart, executive secretary, Wisconsin State Medical Society, Madison.
Problems Connected with Compensation Insurance Dr Roy W. Fouts, Omaha.

Discussing these various subjects were Drs Robert L. Parker, secretary, Iowa State Medical Society, Des Moines, Harold M. Camp, secretary, Illinois State Medical Society, Monmouth, Rasmus V. Williams, Rushford, Minn., John F. D. Cook, secretary, South Dakota State Medical Association, Langford, and James M. Hayes, Minneapolis. The annual county officers meeting of the Minnesota State Medical Association was held the preceding day, February 24.

Medical Bills in Congress—*Hearings* The Senate Committee on Commerce held hearings beginning February 27, on S. 2800 the Copeland bill to prevent the manufacture, shipment

and sale of adulterated or misbranded food, drink, drugs and cosmetics. The Senate Committee on the Judiciary held a hearing, March 1, on S. 1842, proposing to authorize the dissemination of information relating to the prevention of conception, and articles, instruments, substances, drugs and medicines designated, adapted or intended for the prevention of conception. *Changes in Status* S. 2688 has been reported, without amendment, to the Senate (S. Rept. 356). It provides for the validation of payments for medical and hospital treatment of members of the Reserve Officers' Training Corps and of members of the Citizens' Military Training Camps who contracted disease in line of duty while en route to or from and while at camps of instruction. H. R. 6663, the Independent Offices' Appropriation bill, has passed the Senate, with amendments. As amended, the bill provides that any veteran, not dishonorably discharged, suffering from disability, who is in need of hospitalization or domiciliary care and is unable to defray the necessary expenses therefor shall be furnished such hospitalization or care in any Veterans' Administration facility, within the limitations existing in such facilities, irrespective of whether the disability was due to service. A statement under oath by the veteran on such form as may be prescribed by the Administrator of Veterans' Affairs shall be accepted as sufficient evidence of inability to defray necessary expenses. *Bills Introduced* S. 2892, introduced by Senator Wheeler, Montana, and H. R. 8308 introduced by Representative Ayers, Montana, propose to amend existing laws prohibiting the introduction of intoxicating liquor within the Indian country so as to permit its use as a medicine by practicing physicians for patients of Indian blood. S. 2923 introduced by Senator Hatch, New Mexico, proposes to prohibit the shipment and transportation in interstate or foreign commerce of cannabis and its derivatives and compounds. H. R. 8316, introduced by Representative Boland, Pennsylvania, proposes to prevent the manufacture, shipment and sale of adulterated or misbranded food, drugs and cosmetics, and to prevent the false labeling and the false advertisement of such commodities. H. R. 8341, introduced by Representative Tramm, Ohio, proposes to reenact all public laws granting medical or hospital treatment, domiciliary care, compensation and other allowances to veterans of the World War, and their widows and dependents that were repealed by an act approved March 20, 1933. H. R. 8344 introduced by Representative Tramm, Ohio, proposes to reenact all public laws granting medical or hospital treatment, domiciliary care, compensation and other allowances to veterans of the Spanish American War, their widows and dependents that were repealed by an act approved March 20, 1933. H. R. 8350, introduced by Representative Monaghan, Montana, proposes to authorize an appropriation of \$50,000,000 to provide pensions for the aged

Government Services

Number of Veterans Receiving Benefits

As a result of the changes in laws governing benefits to veterans the number of veterans of all wars receiving some form of pension had been reduced from 1,016,561 on March 31, 1933, to 517,171 on Jan. 31, 1934. The number of pensioned dependents decreased from 279,926 to 261,876. The number receiving hospitalization March 31 was 42,823 of whom 27,892 were non-service connected cases, January 31 these numbers had been reduced to 35,973 and 24,189, respectively. Domiciliary or institutional care was being given to 20,544 veterans in March and to 11,623 on January 31. Analyzed by type of benefit, the reduction in the number of veterans of the World War among the beneficiaries between March and November was as follows: service connected wartime, 338,580 to 307,117, non-service connected, 425,894 to 27,283, disabled emergency officers' retirement pay, 6,037 to 1,505, death pensions, 101,553 to 100,462. Disbursements from March 1933 to February 1934 were reduced from \$44,017,141.90 to \$24,110,324.

Four New Veterans' Hospitals to Be Opened

Four new veterans' hospitals with an aggregate capacity of 963 beds built at a cost of \$3,002,014 are to be placed in commission as a result of liberalization of the veterans' relief regulations promulgated under the Economy Act of 1933. The institutions are in Batavia, N. Y., Cheyenne, Wyo., Des Moines, Iowa, and Fayetteville, Ark. Two other hospitals are under construction, a general hospital at San Francisco, and one for nervous and mental diseases at Roanoke, Va.

Sir Arthur Keith's View of the Man of the Future

Sir Arthur Keith, who has devoted a large part of his life to a study of the evolution of man, which is largely embodied in his great work "The Antiquity of Man," has turned from the survey of man's prehistoric ancestors over hundreds of thousands of years to the man of the future. In a press interview he said "From many points of view, the world of the future is not going to be different if it is to be enjoyable. It used to be said that men of the future were going to have big heads and small bodies. They were to live on tabloid peptonized foods. But I don't believe that. I don't think that any purely intelligent form of humanity would survive long." As to the women, he cannot see the time when "Minervas—great gifted women—will be representative of womanhood." Those who will survive will be "the incalculable type, the emotionally unexpected. Those women who enjoy life will live longer than their bramy sisters. Emotions play a much bigger part in woman's life than reason. Women never have colossal brains, but great intuition. Purely rational women would never be able to exist for long. Men prefer the highly emotional woman, but a little intellect is better for her own sake as well as the man's." In regard to the growth of man's brain, Keith is in contradiction to the usual view. "Nature gave primitive man a big brain so that he could solve the great initial problems and have dominance over all the world. But because it has fewer fresh problems to tackle today our brain has dwindled. Nature evidently realized the dangers of the intellect and saw that if the animal in us should be suppressed the human race would soon cease to exist. Broadly speaking, life's pleasures come to us only through the animal that nature has left in us—sex attraction, senses to find pleasure in beauty, music and art, and the instinct of physical endeavor. The capacity to reason took away much of our animal power of intuition."

Regarding the future, Keith says "Although we do not seem to alter nothing which lives is really steadfast. No race can endure without change. Nor can it thrive without an abiding zest for life, sport, amusement and all outlets for human emotion and passion—save debauchery. From these aspects I see no sign of national decay. There is no limit to the progress man can yet make. Intellectually, he has scarcely scratched the surface of his capabilities. Most of us have ten times as much brain power as we are ever likely to need. One reason that man rarely uses his full brain capacity may be that mankind requires only a certain number of thinkers." Asked how he spiritually pictured tomorrow's world, Keith said "My dream is a warless world with an intermarriage of all races and with the English speaking peoples as the custodians of peace. I want democracy to thrive—with each man and woman to share in managing the community, each not to take more than his share of liberty and not to refuse others theirs."

The Villa System for Mental Hospitals

The last word in mental hospitals is the Mental Hospital of the London County Council, erected at Shenley, Hertfordshire at a cost of \$2,600,000 and containing accommodations for 2047 patients. The 'villa system' in contrast to the barrack-like structures in vogue has been followed. The site covers 500 acres and small villas furnished as closely as possible in accordance with home conditions have been erected. Provision has been made for the treatment of all forms of

mental illness, including patients who desire to enter the hospital voluntarily in consequence of temporary mental breakdown. Verandas are a feature of the architectural design and will be used by patients for rest both by day and by night. There are wooded parts of the extensive estate and a farm where men will be provided with congenial work. A large occupation therapy department will form part of the hospital treatment. There will also be occupation for men in workshops and for women in kitchens, laundry and sewing departments. A variety of handicrafts will be available to meet different interests of patients, such as weaving, rug making, embroidery, toy making, leather work and basket making. Men will also be employed at simple joinery, painting, polishing, printing, book binding and brush making.

The Minimum Diet for a Man

The controversy aroused by the publication of two different reports on the minimum diet necessary for a man—one by an advisory committee of the ministry of health, the other by a nutrition committee of the British Medical Association—has been described. The former estimated 3,000 calories and 50 Gm of first class protein and the latter 3,400 calories and 37 Gm of protein daily. The differences between the two reports are to be explored by a conference between representatives of the committees.

Production of Radium in Canada

The high commissioner for Canada in London states that a steady supply of radium is now being maintained from the refinery established at Port Hope, Ont. Although the output is limited the supplies will increase as ore is being made available from the rich deposits now being exploited in the Great Bear Region in the Northwest territories. It is believed that in time Canada will be able to supply the radium need of the empire. The supply so far produced amounts to several thousand milligrams. A portion has been purchased by Ontario for use in the cancer clinics of that province.

Bill to Restrict the Sale of Contraceptives

The open manner in which contraceptives are advertised and displayed for sale is something of a scandal. Lord Dawson, president of the Royal College of Physicians, has introduced a bill in the house of lords, which has received a first reading, to restrict the sale, display and advertisement of contraceptives. The bill is to make it unlawful (1) to sell in any street or public place any contraceptive, (2) to go to the premises of any person and there offer for sale any contraceptive, unless in pursuance of a previous request or the premises are used by a dealer in contraceptives, (3) to display in or outside any shop, so as to be visible outside, any contraceptive or any box or wrapper purporting to contain one, or (4) to send to any unmarried person who has not attained the age of 18 any circular or other document relating to any contraceptive. Contravention of any of these provisions will render a person liable to a fine not exceeding \$100 for a first offense.

The Black Rat in London

The old English black rat was the only species in England 150 years ago but was exterminated by the more powerful brown rat. From the sanitary standpoint it was a much more dangerous animal because it lived in much closer association with man and, by means of its flea, is regarded as responsible for the epidemics of plague that ravaged the country in former times. Another black rat of foreign origin, has made its appearance in England and is receiving the attention of the ministry of health, which has sent a circular letter to the local health authorities of London containing the following "It would appear that modern methods of construction have resulted to a great extent in exclusion from new buildings of the com-

mon brown rat, but that the black rat, by reason of his superior climbing powers, has found his way into the roofs of modern buildings by way of telephone cables and otherwise, and has thus gained access to the kitchens, which are often situated on upper floors. In view of the risk of the introduction and dissemination of diseases by the black rat, there can be no question of the vital necessity for exercising effective measures of control." So far the number of reported black rats is small, but the replies have been received only from boroughs on the outer edge of the area of inquiry. It is expected that the prevalence will be greater in the center, with its less modern buildings. A third species of rat the Egyptian *Mus alexandrinus*, has also arrived from overseas. It is a subspecies of the black rat. In the seaports of Hull and Liverpool the black rat and the Egyptian rat predominate.

The Use of Narcotics by Midwives

The majority of the labors in Great Britain are attended by midwives, a physician being summoned only in cases of difficulty. The question has arisen, How far can midwives be allowed with safety to use narcotic drugs for the relief of their patients? The difficulty that midwives could not be permitted to administer chloroform in the ordinary way has been overcome by supplying them with breakable capsules containing 20 minims. This method has been claimed by Mr. L. C. Rivett who introduced it, as completely safe and fool proof in relieving the intense pains of childbirth. Correspondence is now taking place between the Central Midwives Board and the General Medical Council as to the administration of drugs by midwives. The board drafted a rule. A midwife must not on her own responsibility use any drug unless in the course of her obstetric training she has been thoroughly instructed in its use and is familiar with the dosage and method of administration or application." The council has suggested that the words "save in great emergency" be inserted after the word "midwife."

A Baby with a Tail

The rare condition of a baby born with a tail has been observed at the Metropolitan Hospital. The tail is about 2 inches long, tapers to a point, and is curly and normally sensitive. Removal is proposed. Prof. Julian Huxley has remarked about the case, that different parts of the body develop at different rates during embryonic life. Usually the tail does not develop at all, but in this case apparently it has grown at almost the same rate as the other parts of the body.

Nonsense About Poison Gas

Addressing a branch of the League of Nations Union Dr. F. A. Freeth, F.R.S., said that more nonsense had been talked about chemical warfare than about any other subject in the world. The first gas used for attack in the late war was chlorine, which was fairly deadly, but its deadliness depended on perfect atmospheric conditions at the right moment—a quiet atmosphere and a gentle breeze in the right direction. The Germans let loose a blanket of gas on unsuspecting troops without any protection against it. Naturally, in such circumstances it was effective. But the value of chlorine was now at an end, for gas masks were completely effective against it. The really killing gases were light and consequently easily dispersed by the atmosphere. The heavy gases were more or less immobile and could not move quickly. The only really useful military gas was mustard gas. If a big railway junction was plastered with mustard gas it would be put out of action for three or four days while the experts dispersed the gas. Chemical warfare had got such a hold on the imagination of the civilian population that its main danger was psychologic. If in a gas raid a man could keep his head sufficiently close to the windows put out the fire and wait until the authorities dispersed the

gas, he would be reasonably safe. The scope of gas in warfare was extraordinarily limited and not to be compared with high explosives and machine guns. The percentage of deaths from mustard gas during the war was to casualties from it under 4. Dr. Freeth was confident that it would not be difficult to devise some simple form of apparatus that would completely protect civilians in time of war.

The Brain in Great Musical Composers

Dr. Raoul Blondel delivered before the Academy of Fine Arts an address on the peculiar type of brain of musical composers, which is the foundation of a talent for music. He first reviewed the articles published by Retzius, Siegmund Averbach, Lutritzky and others. He brought out that the brains of many eminent composers present an unusual development of the superior temporal gyrus and of the middle portion of the inferior parietal lobule, or of the supramarginal gyrus and the angular gyrus. The same conditions have been found in the brain of eminent mathematicians. The two gyri are regarded as the centers of memory for graphic signs. He considered the defects produced in the musical faculty by pathologic lesions affecting the language center. Mental disorders influence only the value of the ideas of composers and do not affect the technique, which remains intact in the centers in which it is fixed by memory. The compositions of musicians who have developed mental disease are correct but have lost all originality, which has its origin in the superior psychic centers. Hypertrophies of the parietal and the temporal lobes are brought about by a congenital condition of the cranium, which explains why a talent for music manifests itself in childhood, long before the complete development of the intellectual qualities, as is attested by numerous examples derived from the biography of illustrious composers. One is born a composer—one does not develop the qualities of a composer unless this preliminary conformation exists. Blondel cited the example of two pupils enrolled at present at the Conservatory of Music. The pupils are twin brothers and have a remarkable and equal talent for music. This special conformation of the cranium of musicians may sometimes be observed externally, owing to the abnormal development of the left temporoparietal protuberance. The origin, like that of all cranial dystrophies, is probably associated with some pathologic heredity, the effects of which often are deplorable but in this instance are exceedingly fortunate. Beethoven was the son of an alcoholic addict, and Mozart's family was tuberculous. It would seem that these pathologic accidents occurring, from time to time, while they derange the normal plan of cranial and cerebral anatomy have been the occasion of anomalies that have given rise to exceptional beings, great inventors, great thinkers and great musicians, whose influence on the intellectual progress of humanity has been of signal importance.

Tubercle Bacilli in Sputum in the Absence of Tuberculous Lesions

At the last session of the Societe d'etudes scientifiques de la tuberculose the subject of "Expectoration of Tubercle Bacilli in the Absence of Tuberculous Lesions" was introduced through a communication of Professor Bezançon and Messieurs Paul Brun and Andre Mayer. Such cases are rare, but they have collected twenty-three typical examples in which tubercle bacilli existed manifestly in the sputum in spite of the fact that radiography did not reveal the existence of any pulmonary lesions. Numerous implantations of these sputums and cultures have been made to make sure that it was not a question of pseudo tuberculous bacilli. The persons observed were in good health.

and the phenomenon did not persist in them for a long time. The interesting point is the prophylactic problem in the presence of these germ carriers, who may prove infectious for others. Mr. Bidermann presented a roentgenogram of a person of absolutely normal appearance, although it was found that his sputum contained frankly genuine virulent tubercle bacilli. Mr. Stefani objected that it is possible for lesions to exist that are not revealed by the best roentgenogram. Mr. Weiller cited observations of excretors of tubercle bacilli who, though apparently healthy, developed pulmonary tuberculosis later on.

Military Service of Medical Students

The year of compulsory military service is performed under conditions that vary with the nature of the studies being pursued by the young men. For the students of medicine, who, once they are in possession of their doctor's degree, must be appointed as military physicians, military instruction is replaced by technical instruction. A new regulation provides that this instruction, instead of being given in the infirmaries and the military hospitals of the region in which the student resides, will henceforth be given at the Ecole de médecine militaire du Val-de-Grace, in Paris, where the new doctors of medicine will spend one year, in association with the physicians who have chosen military medicine as their permanent career and who enter this school on leaving the Ecole spéciale de Lyon.

The Death of Pierre Bazy

The death of Dr. Pierre Bazy, from pulmonary congestion, at the age of 80, is announced. He had served as a surgeon to the "hopitaux de Paris" and had become eminent as a urologist. He was a member of the Academy of Medicine and of the Academy of Sciences. A pupil of Guyon, he was the first, in France, to attack surgically tumors of the bladder and to apply preventive antitetanic serotherapy to the wounded.

The Government's Attempt to Abolish Quackery

The new government is planning to license certain *heilpraktiker*. The question of freedom of treatment is to be attacked vigorously and the present unrestrained situation is to be replaced by a regimentation that will deal justly with the whole situation. Following the first congress of lay practitioners in Munich, Nov. 26, 1933, under the auspices of the national-socialists, Dr. Wagner, the federal "leader" of the medical profession, made an announcement from which the following is taken: "I wish to make it perfectly plain that, inasmuch as I, as the leader of the medical profession, am alone responsible for the conduct of medical affairs, I cannot allow any interference or even criticism from persons who, by their attitude, clearly prove that they are not national socialists and that they, furthermore, did not consider it necessary to inform themselves, even superficially, concerning the question that was up for discussion. I wish to emphasize also that, in view of the disturbances that have occurred during the last few days, the affair is not a matter that concerns merely the medical profession but that such machinations disturb important new regulations affecting state medicine and government policies in general and that therefore I shall take vigorous action against any further disturbances in accordance with the principles and practices of governmental control. In particular, I wish to make this plain to certain university circles that consider it necessary to enlist the sympathies and the cooperation of the medical students in furtherance of their reactionary plans which are inimical to the objectives set by the state." Further statements of Dr. Wagner throw light on the situation as it exists today. He has stated that old school medicine par-

ticularly its representatives and instructors at the universities, has taught medical students to use the most complicated methods for establishing the most subtle diagnoses but that man as a whole has too often been neglected. On the other hand, "nature cure methods" had gained an increasing number of adherents since the war.

The question is regarded by the government as of paramount importance. The present legislation, which permits any person without educational qualifications to practice the art of healing, is to be changed, and in its place, in addition to physicians, a definite group of persons will be given the right to practice. This group, designated as *heilpraktiker*, must comply with certain requirements to obtain the right to practice, and their activity will be greatly limited as compared with that of physicians, since their educational preparation will be inferior. The *heilpraktiker* will be restricted to private practice, they will not participate in the field of health insurance or in governmental public health activities—nor in the treatment of venereal diseases. The practice of obstetrics and surgery, and the prescribing and use of certain potent medicines, will be reserved to licensed physicians.

In contrast with their previous status, the *heilpraktiker* will be subject to rigorous supervision by the federal health administration and will be grouped in a rigid league, which will be under the control of the reich. All *heilpraktiker* must be approved by the minister and must belong to the league, those who do not join will not be entitled to practice and, if a member is expelled, he must abandon all forms of practice. Only German citizens of Aryan extraction, and not married to a person of non-Aryan extraction, will be recognized as *heilpraktiker* provided they have completed at least the course in the *volksschule* (eight years) and have incurred no penalties for dishonorable acts. Furthermore, the applicant must have served for one year as an attendant on the sick in one of the hospitals to be designated for that purpose. There will follow an inquiry as to the applicant's general suitability and adaptability for the calling. The examining board will consist of a jurist and two *heilpraktiker*. Then will follow a three-year course in a professional school recognized by the federal minister of the interior the curriculum of which will be established in agreement with the Reichsärztekammer (federal chamber of physicians) and the Heilpraktikerbund. Following the completion of this three-year course, candidates will be examined, especially for their ability to recognize epidemic and infectious diseases. The examining board will be composed of two physicians, three *heilpraktiker* and a chairman. After passing this examination, the candidate must serve for a year as an intern in a hospital or under a physician or a *heilpraktiker*.

It is not the plan to recognize all lay practitioners as *heilpraktiker*. On the contrary, the requirements mentioned above for the training of *heilpraktiker* must be fulfilled, and examinations must be taken by those who have not practiced as *heilpraktiker* continuously since Jan. 1, 1930. The testing as to German citizenship, Aryan extraction, type of education and imposition of previous penalties must be applied in every case.

The further provisions apply important principles of professional medical service to the activities of the *heilpraktiker* and eliminate the disadvantages under which the physicians had to suffer because of their strict professional requirements as compared with those of lay practitioners. *Heilpraktiker* will not be permitted to act as itinerant practitioners or in the service of societies or firms (other than in hospitals and the like). All forms of solicitation or advertising in newspapers and journals and particularly through personal activity in public gatherings, are prohibited. *Heilpraktiker* may designate themselves by no other term.

After five years of uninterrupted activity as a *heilpraktiker*, a person may aspire to a university medical course, if a special

committee, on which the Reichsarztekammer must be represented, shall give its consent. The differentiation lies in the different training received preceding the premedical course. In the government examination, the same performances and the same knowledge must be demanded of the *heilpraktiker* as of the ordinary medical student.

The new regulations here discussed exist, as yet, only in the form of a bill. It is learned, however, from authoritative sources that the enactment of the bill into law is a question of the immediate future. According to the official organ of the Deutscher Aerztevereinsbund and the Verband der Aerzte Deutschlands the principles of the proposed law may be regarded "as acceptable also to the medical profession." Nevertheless, it is said that there is strong opposition to this law in medical circles.

The hopes based on this new and more favorable status of the *heilpraktiker* are shown in statements made at the Essen session of the national-socialist *heilpraktiker* to the effect that their endeavors would be directed toward the elimination of all unqualified elements and the establishment of better educational qualifications within their profession. The number of *heilpraktiker* in Germany does not exceed 4280 and they are ardent opponents of quackery. The regrettable conditions that have existed in the past is shown by an order just issued prohibiting popular health lectures in Prussia. In recent months the order states handbills and posters have been employed to urge attendance at public lectures that deal with attempts to enlighten the public on health problems. Following the lectures consultations on the health of individuals and even applications of treatment are resorted to. Also certain remedies for the healing or prevention of diseases are sold at prices entirely out of proportion to the value of the remedies. This form of solicitation has become a great evil. In order to prevent further damage to the health of the German people meetings of this nature are to be prohibited. Dr. Wagner has issued a further statement to the effect that "quackery will, in the future, be more vigorously combated than heretofore but with this difference that the physicians will no longer oppose the *heilpraktiker* but will make common cause with them against the charlatans." In any event, the proposed legislation offers to the large group that practices the art of healing outside the bounds of regular medicine a way in which to propagate their doctrines in the form of a recognized "school." In the course of time it will be revealed to what extent they are able to establish a worthy school and to create a uniform system. It is not impossible that in this manner valuable forces will be released that have been slumbering for ages in the minds of the common people. The whole undertaking is an experiment, and it is only to be hoped that it will not prove dangerous to the public health.

ITALY

Nov 30, 1933

Studies on Leishmaniasis

At a meeting of the Societa medico-chirurgica, in Catania papers were presented pertaining to leishmaniasis which investigations have shown to be fairly widespread in Sicily. Redaelli reported the results of his investigations on spontaneous visceral leishmaniasis in the dog, calling attention to the relation with similar types occurring in man. On the basis of ten personal observations, the speaker traced the clinical and the anatomohistopathologic aspects of this type defining the disease as a morbid disorder of the reticulo endothelial system.

Baserga discussed his research on the hematopoietic organs of dogs, which served Adler and Theodor in their research on the causative agent of Mediterranean leishmaniasis. He found in leishmaniasis a complete myeloid aplasia which

explains the leukopenia and the lack of pigmentation and is to be associated with the characteristic reticulo endothelial hyperplasia.

Sorge reviewed recent investigations that reveal that sand flies are carriers of Leishmania. *Phlebotomus papatasi* and *Phlebotomus sergenti* are the transmitting agents of Oriental boil, and *Phlebotomus argentipes*, *P. chinensis* and *P. mongolensis* are the transmitting agents of Asiatic kala azar. Mediterranean kala-azar is transmitted by *P. perniciosus* and *P. major*.

Baserga reported that, on a few occasions, he succeeded in finding Leishmania in a disintegrated form within megakaryocytes.

Paradiso and Fiorentino described a method of treatment for kala azar in children, which is more practical than intravenous injections of antimony and potassium tartrate. In twenty-two cases they used aminophenylstibiato diethylamine injected intramuscularly, which had already been successfully employed by Napier in the treatment of kala azar in India. They effected a recovery in 90.9 per cent of the cases in which this treatment was employed.

Zangri reported his use of Guadin in the treatment of leishmaniasis in children. The limited number of cases does not justify any definite conclusion, nevertheless, he states that Guadin is a preparation that has the advantage of being employed subcutaneously, and that in some cases it no doubt has an effective action. But its high toxicity appears to be a serious objection to its habitual use.

Prizzra observed that with intensive treatment of infantile leishmaniasis with antimony preparations, often the disappearance of the fever and of the other morbid symptoms is not observed until several days after the interruption of the treatment. He investigated therefore to discover whether, under such conditions, it is possible to find a deposit of antimony in the organism. He found that to be the case, particularly in children with lesions of the internal organs.

Lecture of Professor Kahn

Professor Kahn of the University of Michigan Medical School delivered a lecture in the great hall of the Clinica medica di Roma, on the serology of syphilis. The speaker demonstrated the technic of the Kahn test for syphilis applying it to eleven serums supplied by the Clinica dermosifilopatica, to which the Meinicke test had previously been applied. The results of the two tests were similar, except that two serums that were negative by the Meinicke test were positive with the Kahn test. Since the two serums were of syphilitic persons who had already been treated, proof was furnished that the Kahn test is more sensitive.

The speaker discussed the Kahn test in relation to the Wassermann test. It is not advisable to rely absolutely on a single method but rather to compare the results of at least two methods employing a different mechanism.

Professor Kahn did not deny the possibility of errors in the Kahn test arising from the preparation of the antigen but added that once in possession of an exact knowledge of the method of preparing the standard Kahn antigen, every analyst would be able to prepare it without great difficulty.

Research on the Etiology of Goiter

At the International Conference on Goiter, at Bern, Prof. G. Pighini of Reggio Emilia reported on research on the etiology of goiter. There are many substances that may modify the structure of the thyroid. Calcium, boron, fluorine and selenium exert on the thyroid a stimulus the effects of which depend on the duration the intensity and other factors. In the etiology of endemic goiter, many factors are involved among which are substances contained in certain plants (cab-

bage, fennel), and probably radioactive substances. Such substances give rise in the organism to a summons throughout the circulation for iodized hormones, and may, up to a certain point, be neutralized by iodine or by thyroidin introduced from without. Such treatment transforms the parenchymatous goiter into a colloidal goiter. According to the modern conception, the lack of iodine is not in itself the cause of goiter. The deficiency of iodine or of thyroid hormone is induced in the organism by a positive goitrogenic agent. A small quantity of iodine, such as is found in regions near the sea and in the plains, appears to favor the prevalence of the basedowian or colloidal types of goiter, whereas a conspicuous lack of iodine, such as is noted in mountain regions, seems to favor the adenomatous and the nodular types.

Professor Cerletti presented the results of his research on the etiology of goiter. He discovered that rats transported from Genoa to a mountain region where there are foci of goiter all became goitrous. But rats raised in a goiter zone do not present goiter if they are kept in boxes, or cages, supplied with filtered air. Rats propagated in Genoa and given regularly water from a goitrogenic zone and scraps from the homes of goitrous persons do not become goitrous. Hence there is no support for the assumption that an infectious factor is involved.

Ancylostomiasis Day

In celebration of the centenary of the birth of Barbardo Ramazzini, the creator of occupational medicine, special meetings were held at the universities of Milan, Pavia, Modena and Padua. Representatives of nine nations were present at Milan, and one feature was the so called ancylostomiasis day, which was under the chairmanship of Professor Perroncito. Quarelli referred to the discovery of *Ancylostoma duodenale*, the common hookworm, by Angelo Dubini (1843). Mazzitelli described the worldwide prevalence of ancylostomiasis. Infestation in Italy is no longer confined to laborers working in subsoils but is spreading to dry soils through the practice of flooding fields with sewage. Professor Devoto, director of the Clinica delle malattie professionali in Milan, spoke on the mode of entrance of *Ancylostoma* into the human body. The enormous number of parasites found at necropsy, and in the feces of patients, after the administration of anthelmintics awakens doubt as to whether so large a number of larvae might have penetrated the skin and followed the course described by Loos. Professor Cavagliano has applied the duodenal tube to many patients and found ova of *Ancylostoma* and young larvae. Penso recommended that these larvae be cultivated in order to determine whether they are truly *Ancylostoma* and to remove the suspicion that other parasitic infestations are involved, such as *Strongyloides* and *Oxuris*.

Verneti brought out that certain subjective symptoms involving the heart are always present. Anemia in such patients is characterized by a notable diminution of hemoglobin. Eosinophilia is present.

Preti studied the toxins produced by *Ancylostoma duodenale* and found that this parasite produces a substance that has a lytic action on red corpuscles.

Penso of Rome explained the means for the protection of the soil against *Ancylostoma*. While it is simple to protect a small workyard or to disinfect it by means of sodium chloride, iron sulphate, lime water and the like, it is more difficult to combat *Ancylostoma* in the open fields. The carriers must first be treated and larvicidal substances should be added to human excrement. One of the most effective larvicidal agents is calcium cyanamide to be sprinkled on the ground, and iron sulphate to be added to cesspools. These measures will prevent also the infestation of persons who eat green foods grown on contaminated fields.

Dr Andreatti's Scientific Challenge

Dr Andreatti has challenged Professors Valagussa and Mancini with respect to the treatment of tuberculous patients. The two professors publicly declared that, on treating tuberculous patients with a polyvalent vaccine proposed by Dr Andreatti, they had found it harmless but ineffective. The challenge suggests that Dr Andreatti treat by his method fifty tuberculous persons of the first degree and fifty persons of the second degree, while a like number shall be treated by Professors Valagussa and Mancini, by the most modern means of treatment, mutual control to be provided and the results of the treatment to be measured within six months. The challenge has been accepted, and the experiment has been begun in the Ospedale riuniti of Rome.

NETHERLANDS

(From Our Regular Correspondent)

Dec 27, 1933

Goiter in the Netherlands

In 1924 Pennink, director of the water supply system of Amsterdam, attempted to prove that the increasing number of companies engaged in the distribution of drinking water had brought about a reduction of the iodine content of the drinking waters by passing them through natural or artificial filters. As a result the central committee for the distribution of drinking water decided to appoint a commission of physicians, hygienists and chemists, to make an investigation of (1) the frequency of goiter in the Netherlands and the concomitant clinical signs and (2) the iodine content of the water and of food products. From the medical point of view, several investigations on goiter in the Netherlands had previously been made. In 1907 it was found that there were more goiters among the enlisted men from Utrecht than among the recruits from the rural districts. In 1916 Kappenberg reported that field rats present no goiters, whereas many semidomesticated rats, raised in Utrecht, are affected. A little later, Potter carried out an experiment on rats. Those fed drinking water from the city of Utrecht presented a goiter, others fed spring water remained exempt. In 1918 an inquiry instituted in different cities on the frequency of goiter yielded the following results: Utrecht 66 per cent, Leeuwarden 35 per cent, Middelburg 17 per cent, Breda 84 per cent.

The principal conclusions of the investigating commission are as follows. The goiter observed in the Netherlands is of the same nature as the goiter existing endemically in Switzerland, Tyrol and elsewhere, but it differs from the quantitative point of view. It appears chiefly in the localities in which the drinking water and the food products have a low iodine content. In many cases, waters near the earth's surface contain more iodine than the waters from the deeper strata. Waters from just under the surface of the earth collected by water distribution companies have a low iodine content. These two facts may serve to explain the greater frequency of goiter arising since the increase in the number of water distributing agencies.

The prophylaxis of goiter consists in the use of table salt containing iodine or in the iodization of the drinking water. Most persons with goiters are not aware of their disorder. Only a few persons with goiter present associated disturbances: nervousness, digestive disorders, and the like. From this last point of view, the commission's report has deficiencies that should be remedied by a more complete report, for it is of great importance to know whether the goiters observed in the Netherlands are of a simple nature or toxic.

The Netherlands Society of Tropical Medicine

The Netherlands Society of Tropical Medicine was founded twenty-five years ago, when tropical medicine began to reap

the fruits of the discoveries of Manson, Ross, Laveran, Koch, Schaudinn and others Sept 27, 1907, on the occasion of the fourteenth International Congress of Health and Demography, held in Berlin, the International Society of Tropical Medicine was founded as a result of the initiative of Manson, Celli, Ross, Nutall, De Vogel and others. The countries that had no society of tropical medicine were asked to establish one, and this task in the Netherlands fell to Dr Van Der Scheer, who called a first meeting of the Netherlands Society of Tropical Medicine for Dec 8, 1907, at The Hague. Since then, this society has amply fulfilled the tasks imposed by its constitution. It was this society that defended the interests of tropical medicine at the time of the creation of the Colonial Institute, demanding complete training in this branch of medicine for physicians chosen for the colonies. It furnished also the detailed government report on the epidemic of plague in Java. But its principal task consists in maintaining the relations between the physicians of the Netherlands and those of the Dutch East Indies, and one need only inspect the reports rendered to the society to become convinced of the diversity and high scientific content of the subjects treated.

Resolution Concerning Surgical Tuberculosis

The Netherlands Association of Phthisiologists has passed the following resolution:

The care of patients affected with surgical tuberculosis constitutes a branch of the crusade against tuberculosis. Hence it is desirable that the organizations aiding in the crusade against tuberculosis in general pay more attention to such patients than they have done heretofore. The present organization of the crusade against tuberculosis in the Netherlands is fully competent to take care of the interests of these patients.

The association decided to bring this resolution to the knowledge of the general commissioner of health and of certain associations named:

Mutual Aid Societies

Last year an inquiry was instituted concerning the status of the mutual societies furnishing medical aid in the Netherlands. Nearly all the societies gave the information requested. In general, they expressed a preference for mutual societies. They do not agree with the suggestion that possibly the introduction of uniform contributions would be desirable. The opinions of the societies are divided with respect to the minimum tariff to be applied and to the family contract, both as regards ordinary medical care and attendance by specialists, and the amount to be paid for hospitalization.

Marriages

FRANK F THWEATT, JR., A Surg, U S Public Health Service, to Miss Hallie Lee Farrar of Arrington, Va., in New York, Dec 22, 1933.

ELIZABETH MAPELSDEN RAMSEY, New Haven, Conn., to Mr Hans Alexander Klagsbrunn of Washington, D C, January 27.

EDWARD GORDON ABLE, Newberry, S C, to Miss Mary Elizabeth Dowling at Lancaster, Dec 16, 1933.

RICHARD A STREET, JR., Memphis, Tenn., to Miss Catherine Noble of Fayette, Miss., Nov 25, 1933.

WILLIAM A HART, Columbia, S C, to Miss Elizabeth Trice of Federalsburg, Md., January 1.

LEWIS G CRAWFORD to Miss Anna K McBride, both of Harrisburg, Pa., Dec 20, 1933.

JENNINGS CRAWFORD LITZENBERG to DR OLGA S HANSEN, both of Minneapolis, recently.

HOWARD E WILEY to Miss Edith Katherine Wahlbom, both of Rockford, Ill., January 10.

OSCAR L ZESCHIN, Seattle, to Miss Lorene Westby of Auburn, Wash., recently.

JOSEPH L DAMOND to Miss Alice Alpert, both of New York, February 25.

Deaths

George Bright Young ♂ Senior Surgeon, U S Public Health Service, Charlottesville, Va., University of Maryland School of Medicine, 1887, entered the U S Marine Hospital Service as assistant surgeon in 1890, in 1905 was promoted to surgeon, in 1920 to senior surgeon and in 1924 retired on account of age, during the prevalence of cholera in Europe in 1893 he was sent to take charge of the shipment of emigrants and cargoes from various ports, during the yellow fever outbreak in 1897 he had charge of interstate quarantine in portions of Tennessee, Mississippi, Alabama and Arkansas, at which time he established the first extensive system of train inspection, medical officer in charge of the U S Marine Hospital at Chicago, 1905-1908, member of the House of Delegates of the American Medical Association, 1908-1911, formerly associate professor of preventive medicine, University of Virginia Department of Medicine, health commissioner of Chicago, 1911-1915, health officer of Charlottesville, Albemarle and University, Va., aged 73, died, February 13, of hemiplegia.

Walter James Highman ♂ New York, Columbia University College of Physicians and Surgeons, 1905, secretary of the Section on Dermatology, American Medical Association, 1918-1920, and chairman, 1920-1921, member of the American Dermatological Association, formerly clinical professor of dermatology and syphilology, University and Bellevue Hospital Medical College and associate professor of dermatology, New York Post-Graduate Medical School of Columbia University, served during the World War, dermatologist to the Mount Sinai Hospital, associate dermatologist to the Lenox Hill Hospital and pathologist to the University and Bellevue Medical College Dispensary, author of "A Textbook on Dermatology", aged 54, died January 24 of cerebral hemorrhage.

John Elliott Boyd ♂ Jacksonville, Fla., Medical College of the State of South Carolina, Charleston, 1894, past president of the Duval County Medical Society, fellow of the American College of Surgeons, veteran of the Spanish American and World wars, aged 64, for many years on the staffs of Duval County Hospital, St Luke's Hospital and St Vincent's Hospital, where he died, January 26, of acute encephalitis.

Albert Vernon Phelps, Westerly, R I, Medical College of Ohio, Cincinnati 1885, formerly adjunct professor and demonstrator of anatomy at his alma mater, at one time professor of anatomy at the Laura Memorial Woman's Medical College, Cincinnati, Cincinnati College of Dental Surgery and the University of Cincinnati College of Medicine, aged 75, died, February 12 of carcinoma of the bladder and prostate.

Albert Martin Farrell ♂ Two Rivers, Wis., State University of Iowa College of Medicine, Iowa City, 1898, fellow of the American College of Surgeons, served during the World War, past president of the city council, surgeon to the Holy Family Hospital, Manitowoc and the Municipal Hospital, aged 57, died January 12, at Hongkong, China, of myocarditis.

Clyde Clement Bohannon, Daytona Beach, Fla., Homeopathic Medical College of Missouri, St Louis 1902, member of the Florida Medical Association, past president and secretary of the Volusia County Medical Society, on the staff of Halifax District Hospital, aged 58, died, January 29, of myocarditis.

Augustus Keefer Boom ♂ Adams, Mass., Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1888, past president of the Berkshire County Medical Society, on the staff of the W B Plunkett Memorial Hospital, aged 67, died, January 24, of lobar pneumonia.

Wilmer Brinton, Baltimore University of Maryland School of Medicine, Baltimore 1876, member of the Medical and Chirurgical Faculty of Maryland, formerly professor of obstetrics, Baltimore Medical College, aged 79, died, February 12, of chronic endocarditis, arteriosclerosis and diabetes mellitus.

Norton Eugene Winnard, Eugene, Ore., Chicago Homeopathic Medical College, 1890, Rush Medical College, Chicago, 1892, member of the Oregon State Medical Society, on the staff of the Pacific Hospital, aged 69, died, Nov 30, 1933 in Portland, of arteriosclerosis, myocarditis and chronic nephritis.

Joseph Bringham ♂ Felton, Del., University of Pennsylvania School of Medicine, Philadelphia, 1898, formerly secretary of the Kent County Medical Society, served during the World War on the staff of the Milford (Del.) Emergency Hospital, aged 62, died, February 6 of cerebral hemorrhage.

Robert Eugene Doern, Stockbridge, Wis., Milwaukee Medical College, 1909, veteran of the Spanish-American and World wars, aged 57, died, January 27, in the Edward Hines, Jr., Hospital, Hines, Ill., of angiosarcoma of the skin of the Abdomen with metastasis to the left axilla and lung

George Henry Humphrey Smith, Little Falls, N. Y., Albany (N. Y.) Medical College, 1903, member of the Medical Society of the State of New York, for many years county coroner, on the staff of the Little Falls Hospital, aged 54, died, January 7, of cerebral hemorrhage.

George Macdonald, Calgary, Alta., Canada, McGill University Faculty of Medicine, Montreal, Que., 1889, formerly registrar of the College of Physicians and Surgeons of Alberta, served during the World War, on the staff of Colonel Belcher Hospital, aged 70, died, Nov. 4, 1933

Charles Richard Reaves, Greensboro, N. C., University of the South Medical Department, Sewanee, Tenn., 1906, member of the American Academy of Ophthalmology and Otolaryngology, on the staff of St. Leo's Hospital, aged 49, died, February 6, of pneumonia

Charles Spurgeon Warwick, Santa Barbara, Calif., University of Oregon Medical School, Portland, 1929, member of the California Medical Association, on the staff of St. Francis Hospital, aged 39, died, January 27, as the result of an automobile accident

Augustus Adelbert Young, Newark, N. Y., Syracuse University College of Medicine, 1879, member of the Medical Society of the State of New York, formerly mayor and health officer, aged 84, died, January 21, in a local hospital, of pneumonia

George D. Butler, Pulaski, Tenn., University of Louisville (Ky.) School of Medicine, 1876, at one time member of the state board of medical examiners, formerly county health officer, aged 77, died, January 16, at Wales, of cerebral hemorrhage

James Alexander Albright, Somerville, Tenn., College of Physicians and Surgeons, Baltimore, 1882, formerly secretary of the state board of health and state senator, aged 73, died, February 2, in the Methodist Hospital, Memphis, of uremia

John Schafer Schneller, Catasauqua, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1910, fellow of the American College of Surgeons, on the staff of the Sacred Heart Hospital, Allentown, aged 48, died, February 6

Charles Walter Frink, Elkhart, Ind., Rush Medical College, Chicago, 1887, member of the Indiana State Medical Association, on the staff of the Elkhart General Hospital, aged 71, died, January 27, of carcinoma of the sigmoid

Samuel Cummings, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1888, University of the City of New York Medical Department, 1888, member of the American Roentgen Ray Society, aged 67, died, Dec. 18, 1933

Thomas W. Brockbank, Philadelphia, College of Physicians and Surgeons, Baltimore, 1885, for many years on the staff of the Germantown Dispensary and Hospital, aged 73, died suddenly, February 8, of coronary thrombosis

George Arthur Ings, Fort McMurray, Alta., Canada, L.R.C.P., L.R.C.S., Edinburgh, 1890, and L.F.P.S., Glasgow, 1890, served with the Canadian Army during the World War, aged 73, died, Oct. 11, 1933, in Edmonton

Otto Frithiof Johnson, St. Paul, Minneapolis College of Physicians and Surgeons, 1902, formerly coroner of Sibley County and member of the school board of Winthrop, aged 59, died, January 8, of carcinoma of the liver

James Hugh McCort, Sag Harbor, N. Y., University of Buffalo School of Medicine, 1889, served during the World War, aged 69, died, January 14, of coronary occlusion, coronary sclerosis and diabetes mellitus

George Marshall Watson, Manchester, N. H., Baltimore Medical College, 1893, served during the World War, formerly member of the school board, aged 65, died, Dec. 13, 1933, of carcinoma of the larynx

Henry N. Hess, Fryburg, Pa., College of Physicians and Surgeons, Baltimore, 1882, member of the Medical Society of the State of Pennsylvania, bank president, aged 80, died, January 7, of diabetes mellitus

Medicus Emmett Ellis, Hampton, S. C., North Carolina Medical College, Charlotte, 1914, member of the South Carolina Medical Association, aged 44, died, January 31, in the Es Dorn Hospital, Walterboro

Elbin Jordan Johnson, Claysville, Pa., Western Pennsylvania Medical College, Pittsburgh, 1895, member of the Medi-

cal Society of the State of Pennsylvania, aged 65, died, Dec. 31, 1933, of heart disease

William James Baird, Boulder, Colo., University of Maryland School of Medicine, Baltimore, 1881, member of the Colorado State Medical Society, aged 72, died, February 2, of pernicious anemia

Mack Hickman, Indianola, Iowa, Keokuk Medical College, College of Physicians and Surgeons, 1906, member of the Iowa State Medical Society, aged 57, died, January 26, of osteomyelitis of the femur

David Lisle Conway, Syracuse, N. Y., Syracuse University College of Medicine, 1909, on the staff of St. Joseph's Hospital, aged 50, died, February 2, in St. Petersburg, Fla., of chronic nephritis

John Mabie Hasbrouck, Garnerville, N. Y., Bellevue Hospital Medical College, New York, 1884, aged 71, died, January 12, in the Vassar Brothers Hospital, Poughkeepsie, of chronic myocarditis

William Josiah Thomas, Charleston, W. Va., College of Physicians and Surgeons, Baltimore, 1892, member of the West Virginia State Medical Association, aged 61, died, Dec. 2, 1933, of angina pectoris

Jefferson Lee Atkinson, Campbellsville, Ky., University of Louisville School of Medicine, 1887, formerly secretary of the Grant County Medical Society, aged 70, died, January 29, of heart disease

Crittenden Augustus Hawley, New Paris, Ohio, Miami Medical College, Cincinnati, 1891, formerly county coroner, health officer and member of the school board, aged 78, died, February 4

Max Culbertson Barrett, Knightstown, Ind., Indiana University School of Medicine, Indianapolis, 1913, aged 44, died, February 5, in a sanatorium at Martinsville, of mesenteric thrombosis

William John Wilkinson, Sellersville, Pa., Jefferson Medical College of Philadelphia, 1891, formerly on the staff of the Grand View Hospital, aged 67, died, January 2, of uremia

John Harris Orbison, Hoshiarpur, Punjab, India, University of Pennsylvania School of Medicine, Philadelphia, 1886, formerly a medical missionary, aged 74, died suddenly, January 4

Robert Benjamin Chastain, Calhoun, Ga., Emory University School of Medicine, Atlanta, 1920, aged 39, died, Dec. 14, 1933, of chronic nephritis, heart disease and hypertension

Johannes George Arthur Weiss, San Antonio, Texas, University of Zurich Faculty of Medicine, Zurich, Switzerland, 1891, aged 71, died, January 25, of chronic myocarditis

Louis Dunster Becker, Colon, Mich., University of Michigan Medical School, Ann Arbor, 1925, member of the Michigan State Medical Society, aged 35, died, February 20, of tularemia

Anna Johnston, Pittsburgh, Cleveland Homeopathic Medical College, 1898, aged 72, died, January 21, of carcinoma of the mediastinum with metastasis to the right lung and abdomen

Carl Hempel Reed, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1882, aged 73, died, February 6, of bronchopneumonia and prostatic obstruction

Emma M. Higginson, Nashville, Tenn., University of Nashville Medical Department, 1901, aged 66, died, January 25, of chronic valvular heart disease, and pulmonary embolism

John Carrol Etherton, Chicago, St. Louis College of Physicians and Surgeons, 1894, aged 77, died, January 29, of carcinoma of the prostate and chronic myocarditis

Nathan Hall Blakeley, Lincoln, Neb., John A. Creighton Medical College, Omaha, 1910, member of the Nebraska State Medical Association, aged 64, died, Dec. 29, 1933

Metius M. Eckelman, Elkhart, Ind., University of Pennsylvania School of Medicine, Philadelphia, 1894, aged 64, was found dead in bed, February 5, of heart disease

Walter Karl Hoover, Lovington, Ill., Rush Medical College, Chicago, 1888, aged 77, died, January 15, in the Peoria (Ill.) State Hospital, of pulmonary abscess

Samuel Binz Hays, Columbus, Ohio, Kentucky School of Medicine, Louisville, 1892, served during the World War, aged 68, died, January 19, of pneumonia

Mary Ozias Cromer, Union City, Ind., Miami Medical College, Cincinnati, 1904, aged 66, died, February 2, in a hospital at Greenville, Ohio, of pneumonia

Byron Stone, North Oxford, Mass., Jefferson Medical College of Philadelphia, 1877, member of the Massachusetts Medical Society, aged 83, died, Dec. 28, 1933

William Lemos Stone, Homer, La., Louisville (Ky.) Medical College, 1893, served during the World War, aged 64, died, Dec 27, 1933, of coronary thrombosis

Aaron E. Armstrong, Knoxville, Tenn., Hospital College of Medicine, Louisville, Ky., 1889, aged 80, died, February 11, of a fractured hip received in a fall

Samuel Franklin De Vore, Sioux City, Iowa, Chicago Homeopathic Medical College, 1895, aged 66, was found dead, January 26, of coronary thrombosis

Walter Harry Abbott ⊕ Warner N. H. Dartmouth Medical School, Hanover, 1892, aged 64, died January 10 of carcinoma of the lung and liver

Edwin Foster Wakefield, Pasadena, Calif. Rush Medical College, Chicago, 1900, formerly mayor of Chagrin Falls, Ohio, aged 60, died, January 23

Leonard J. Pharr, Conyers, Ga., University of Georgia Medical Department, Augusta, 1901, aged 52, died January 14, in a hospital at Atlanta

William Hughes Cole, Minor, Hill, Tenn. University of Nashville Medical Department, 1906, aged 54, died, February 6 of influenza and pneumonia

George Henry Heald, Takoma Park, Md. Cooper Medical College, San Francisco 1893, aged 72, died January 22 of cardiorenal vascular disease

Joseph P. E. Gamache, Pont Rouge, Que. Canada Laval University Faculty of Medicine, Quebec, 1913, aged 54, died, Dec 10, 1933, in Quebec

Solon William Cameron, Chicago, Rush Medical College Chicago, 1928, aged 39, died February 15 of angina pectoris and coronary occlusion

Alexander Joseph Riopelle, Lawrence, Mass. (licensed in Massachusetts by years of practice), aged 74, died January 25 of pernicious anemia

William E. H. Bondurant, Memphis, Mo. Missouri Medical College, St. Louis, 1885, aged 79, died January 30 of cerebral hemorrhage

Simeon Madison Wilhite, Decatur, Ala. Memphis (Tenn.) Hospital Medical College, 1891, aged 72, died, Dec 29, 1933, of bronchopneumonia

Ernest LaFayette English, West Asheville, N. C. University of Georgia Medical Department, Augusta 1916, aged 47, died, January 11

William J. Hunt, Lake George, N. Y. College of Physicians and Surgeons, Baltimore, 1891, aged 70, died, January 2, in Richmond, Va.

Jacob E. Longacre ⊕ Weaversville, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1894, aged 63, died January 15

Thomas Morgan Mitchell, Fort Smith, Ark. University of Tennessee Medical Department, Nashville, 1892, aged 76, died, January 23

Benjamin Franklin Tubergen ⊕ Chicago, Chicago College of Medicine and Surgery, 1916, aged 52, died, February 18 of myocarditis

John Peat Mackie, Toronto, Ont. Canada, Queen's University Faculty of Medicine, Kingston 1922, aged 53, died, Dec 15, 1933

William Wesley Baker, St. Paris, Ohio, Toledo Medical College, 1885, aged 72, died, February 3, of cerebral hemorrhage

William French Thurston, Santa Monica, Calif. L.R.C.S., England, and L.R.C.P., Edinburgh 1866, aged 91, died Dec 30, 1933

William Weaver Stewart, Columbus, Ga. Bellevue Hospital Medical College, New York, 1890, aged 68, died, Dec 24, 1933

William W. Wilkins, Eastville, Va. College of Physicians and Surgeons, Baltimore, 1874, aged 86, died Dec 16, 1933, of senility

Anton Biankini ⊕ Chicago, University of Vienna Faculty of Medicine, Wien, 1888, aged 73, died February 8 of gastric ulcer

Harry Loyd Emmett, Fonthill, Ont. Canada, University of Toronto Faculty of Medicine 1908, aged 52, died Dec 16, 1933

Ralph W. Strong, Denver, Hahnemann Medical College and Hospital, Chicago, 1890, aged 76, died Dec 27, 1933

Martin L. Foster, Los Angeles (licensed in Kansas in 1901), aged 88, died January 23 of pneumonia

EXAMINATION FOR AMEBIASIS

To the Editor—The special articles on the outbreak of amebiasis in Chicago are most commendable. In a recent one you suggest that the stools should be examined one month after cessation of treatment, the inference being that if the results are negative the patient is cured and parasite free. In my experience with this disorder I have found that one cannot be sure that the patient is parasite free (which condition should be accomplished if possible) without this being judged by examinations made four times in the year after the cessation of treatment. At one month after active treatment the stools usually are free from the vegetative forms and so few cysts are present that they are not found. For each of these three month examinations (in the absence of symptoms) the gravitation or sedimentation methods for cysts are the most important and these will often disclose the carrier. Such carriers should have courses of active treatment after every positive finding of cysts. Briefly, one cannot be sure of a parasite free cure by an examination carried out one month after treatment but at least three specimens of stool should be examined at each three months interval.

ANTHONY BASSLER, M.D., New York

NIGHT BLINDNESS

To the Editor—The case report of Drs. Wilbur and Eusterman on the subject of night blindness (THE JOURNAL, February 3, p. 364) is of more than ordinary interest.

I entered the navy when all the sailing ships had not yet disappeared from active commission. In fact, my first cruise was on such a ship and there I listened in the ward room to remarkable stories of night blindness and moon blindness alleged to have appeared among the crews of merchant ships. At the time I swallowed these stories with a grain of salt but later as I became more familiar with the writings of the ancients I was struck with the more or less common occurrence of descriptions of this disease among the earliest Greek, Arabic and Latin writers.

Hippocrates describes the disease in the second book of *Protrhetics*. He says:

It is most apt to attack the young of either sex and passes off spontaneously on the fourteenth day or in seven months and in some cases it lasts the full period of a year. Its duration may be estimated from the strength of the disease and the age of the patient. They are relieved by deposits that determine downward but these rarely occur in youth. Married women and virgins that have the menstrual discharge rarely are subject to the complaint. Persons having protracted defluxions of tears who are attacked by nyctalopia are to be questioned whether they had any previous complaint of the head.

Back of these observations of this earliest medical observer is the suggestion that it was a disease not uncommon. Such Byzantine physicians as Alexander of Tralles and Paul of Aegienta writing a thousand years later than Hippocrates devote a chapter to the disease. The latter says:

The disease called nyctalopia the patient sees during the day but at sunset his vision becomes dimmer and when night comes on he does not see at all. We must affect a cure by bleeding from the arm and the angle of the eye then purging or evacuating by a clyster and afterward ordering masticatories or sternutories. Before food we give hyssop to drink or rue but if the disease do not yield we must again administer the purgative medicine formed from scammony and castor anoint with clarified honey and make the patient close his eyelid so as to retain the fluid application. Or of burnt alum p. ii of fossil salt p. i triturate with honey and anoint. Another: Having roasted the liver of a goat collect the ichor during the roasting and anoint but give him the liver itself to eat or boil and direct the vapors to be received with open eyes.

If some of the foregoing seems silly on the surface there is at least a grain or so of ancient experience, in the observa-

tion alike of the antiquity of the disease and of the antiquity of a dietetic treatment

Among the Arabs, Rhazes (chapter $\lambda\lambda\lambda\lambda$, tract ν , De nictolopis, λ qui post solis occasum non vident) divides the disease into no less than three varieties

The introduction of lime juice in the British navy as a prophylactic against the scurvy came about in a curious way, and not entirely on medical recommendation. After its introduction, scurvy was regarded as a disgraceful disease, not lightly mentioned, and, although lessened, it appeared during the long voyages, particularly of the Australian prison ships. There was a tendency to write about the scurvy diseases under other names. Thus, another thousand years after the Byzantine physicians mentioned may be noted the appearance of nyctalopia in the British Black Fleet in 1854. The acting deputy inspector of the fleet John Rees, gives an account of an epidemic of twenty-five cases of nyctalopia and nineteen cases of scurvy. He had little faith in the efficiency of lime juice. The first case of scurvy appeared in May after fifty days on salt provisions, without fresh food. Twenty-five cases of nemeralopia (night blindness) were coincidentally reported from five ships.

His testimony on nyctalopia is summed up in the following

Symptoms of that disease [scorbutus] and indeed these conclusions are arrived at, notwithstanding that in many instances fresh provisions being issued the hemeralopia disappeared before any more palpable symptoms of scurvy developed. *This frequently happens in the Navy.* The ship arrives in port in the nick of time, fresh provisions are issued, the hemeralopia cases are cured and the presence of scurvy never suspected.

With regard to lime juice as a prophylactic I shall not enter into that question believing it would only be to add another instance to the many that already exist of the failure of an absolute preventive of scurvy. On May 21 fresh provisions were produced consisting at first of indifferent beef and onions but soon afterwards a good beef and a mixture of onions and fresh vegetables, causing the rapid disappearance of all traces of scurvy.

The symptom of nyctalopia has frequently appeared in Russia with the lenten fasts. For a long time it was attributed by seamen to sleeping on deck in the moonlight, and various works have attributed it to strong light and glare of the sun. I may simply add that during many years of service in the navy, much of it on board of hospital ships serving with large fleets, thousands of men in the glare of the sun all day, no case of night blindness has ever come to my attention. The modern supply of fresh food in the fleet is the condition that has changed for the sun and the moon continue to shed their beams as of yore.

ARGYRIA FROM USE OF SILVER PROTEIN PREPARATIONS

To the Editor—In view of the timely remarks emphasizing the lurking danger in the indiscriminate use of neosilvol, a colloidal silver preparation, in disorders of the upper respiratory tract, as recently reported in THE JOURNAL (January 20, p 202) by H K Berkley of Los Angeles, I am constrained to add my experience with another equally widely used and advertised silver salt, viz, argyrol.

My personal unfortunate experience with argyrol covers two cases and knowledge of a third. Briefly, the case of marked argyria is that of a spinster, aged 60, who has for years had argyrol in 10 per cent solution in her possession as a constant household remedy. This patient has been subject to frequent colds and at every such provocation has been in the habit of instilling a few drops of the silver solution in both nostrils. She now has the unmistakable and of course indelible facial stain of argyria. A similar case in this city is known to me both these women finding themselves under the necessity of wearing veils when appearing in public.

A second case of my own concerns a man who has long been instilling argyrol into the eyes because of ectropion and chronic

conjunctivitis. His bulbar conjunctivae now have a negroid stain, and his skin is just beginning to exhibit a faint dusky hue.

That neosilvol and argyrol are valuable therapeutic agents, when in proper hands, is not to be denied, but their indiscriminate and prolonged use by the lay public is here shown to be dangerous. One has but to be confronted with a single case of pigmented skin so characteristic of argyria to realize how great a disaster this really is. That these cases enjoy a comparative rarity is doubtless true, but I venture the assertion that the publicity here given will uncover many others thus far unreported (one such from the use of neosilvol has already come to my notice).

It is to be hoped that the manufacturers of these useful silver preparations will take steps to combat the danger that may follow their prolonged and indiscriminate use, and by publicizing this information safeguard the buying public without, at the same time, endangering unduly their financial interest in these drugs. And it is to be hoped too, that physicians will take cognizance of the harm that may result if they fail to give fair warning of danger lurking in the too free use of these silver salts.

BOVINE TUBERCULOSIS

To the Editor—Referring to the editorial in THE JOURNAL, January 6, on bovine tuberculosis, I may be able to add something of interest as I was in the thick of it twenty-three years ago when health officer in this city. On my arrival here from Chicago in 1902 I was amazed to see the large number of children, estimated at about 15 per cent, from 1 to 15 years of age, afflicted with what is now known to be bovine adenitis. This condition continued to increase until 1911, as the etiology had not been definitely settled. I began the search at once on my appointment as health officer, and having seen many cattle with lumpy necks and recalling Dr Jenner's experience with smallpox, I had a veterinary surgeon give tuberculin tests to the cows and they proved to be positive. The crucial test solved the enigma and the milk was charged with carrying bovine bacilli, and the respiratory pathologic changes in the cows confirmed the diagnosis. This was before settlement from the laboratory abroad.

According to observations here, the bovine tuberculosis did not cause a high mortality. The morbidity was principally in the adenitis, in which the lymph glands in the neck were markedly involved. There were some bone and joint tuberculous cases as well as also a few cases of tuberculous meningitis. There were many cases of scrofuloderma, rickets and malnutrition, doubtless in latent cases of cachexia as sequelae.

The milk was ordered pasteurized and the cows slaughtered and pandemonium reigned supreme. There was a perceptible falling off in the number of enlarged lymphatic glands in three years, and in five years not a vestige of it remained and not one case has developed in the last sixteen years. New sanitary measures were instituted, the milk standardized and the testing of the cows continued until six years later, when the state of Michigan enacted laws governing it.

The testing of the cows and the pasteurizing of the milk are undoubtedly the greatest factors in the reduction of the mortality of pulmonary tuberculosis. We cannot, however, brag particularly in the state of Michigan as the number of cases of tuberculosis reported in 1933 was 7,094, just nine less than recorded in 1932. The evaluation of treatment in the preventorium under the present regimen is not meeting with the success anticipated. The fact of the latency of the disease is too largely overlooked and a false hope entertained that too many children can be reconditioned without observation when the disease is in the state of arrest. It certainly must be that

dietetics and hygienics have not met the approval of the close observer. I incline more toward medicine year by year.

The world has waited fifty years for the production of a vaccine, serum or something to immunize, and although the laboratorians have been working faithfully, none have materialized. However, physicians must keep on attacking the disease in its incipience and not wait until "the water has all gone over the dam" and a respiratory pathologic condition has developed.

S M JAMES, MD Marquette Mich

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

TREATMENT OF EARLY SYPHILIS

To the Editor—In the early part of October 1933 a man aged 30 unmarried appeared at my office with a chancere of the right thigh of three weeks duration. It was situated about 6 inches from the genital region and he was unable to explain its origin even after detailed questioning and careful survey of contacts. Darkfield illumination revealed the presence of spirochetes and both Wassermann and Kahn reactions were 4+. Treatment was instituted immediately—nearsphenamine weekly starting with 0.3 Gm and increasing to 0.6 Gm at each injection. Mercuric salicylate in oil 1 grain (0.065 Gm) in 1 cc, was also given weekly alternating with the nearsphenamine. In all fourteen injections of nearsphenamine totaling 6.8 Gm have been given twelve injections of mercuric salicylate and three injections of iodobismuthol. It is planned to give two intravenous injections of sodium thiosulphate (0.5 Gm) and no further nearsphenamine for the next ten weeks during which time bismuth will be given twice a week with iodide by mouth. Thereafter I plan to resume the first course—nearsphenamine and mercury—alternating again after twelve weeks with bismuth until at least a full year's treatment without any rest has been given. A spinal Wassermann test will be made after the present bismuth course as will also a blood Wassermann. As yet no secondary manifestations have appeared and the patient is in excellent health. At the first injection of nearsphenamine he reacted with a nitritoid crisis relieved by epinephrine which has never reappeared. The young man is engaged to be married. 1. Is this course of therapy adequate and would you recommend any modifications? 2. Are secondary manifestations likely to appear considering the early and intensive treatment given? 3. Is kissing to remain interdicted and for how long? 4. Apart from the question of transferring the infection (the chancre having healed completely) is protected coitus harmful to the patient? 5. When may he be permitted to marry? 6. Can a nitritoid crisis be expected with the resumption of arsphenamine? Please omit name and address.

MD New York

ANSWER—The system of treatment for seropositive primary syphilis suggested by the inquirer is a fair example of a combined nearsphenamine-mercury-bismuth technic of treating early syphilis. It might be criticized in that the least effective and worth while of all available mercurials is being used at the most critical period of the disease, namely, the first course of combined arsenic and heavy metal treatment. It would be preferable to give the bismuth compound with the nearsphenamine and to postpone the mercurial until the interval between courses of arsphenamine. Moreover, it is to be noted that the ten weeks interval between the two nearsphenamine courses is longer than necessary and subjects the patient to very definite risk of recurrence under the heavy metal. This would be even more true were mercury used between the arsphenamine courses instead of bismuth, an additional reason, in view of the suggestion just made, for shortening the interval between the nearsphenamine courses to something approximating six weeks.

Mention is made of a spinal Wassermann test, which of course is a totally inadequate procedure if literally taken; the examination of the spinal fluid, when done, should include a quantitative Wassermann test, an accurate cell count on a blood-free fluid, a colloidal test on the fresh fluid (preferably mastic or benzon), and a protein estimation. The total of nearsphenamine injections in a routine such as this should approximate thirty to thirty-five, and if a maximum dose of heavy metal is employed each time it will be necessary to watch the kidneys closely to guard against accumulative effect and to give the injections of the nearsphenamine with extreme slowness. The dosage of nearsphenamine should not exceed 0.6 Gm. If a mercurial salt is to be employed, mercuric succinimide corrosive mercuric chloride or red mercuric iodide is suggested in place of mercuric salicylate. The interval between injections of the soluble mercurial salt should be shortened to two days.

The risk of appearance of secondary manifestations as a recurrence is greater in seropositive primary syphilis than in the seronegative phase of the disease. For this reason it is doubly important that treatment should be continuous and without complete rest intervals for one year from the time of disappearance of all clinical and serologic signs.

With reference to the specific numbered items, kissing on the lips should be interdicted for an indefinite period, determined by the course of the case, and should be especially avoided after the course of treatment is completed and the patient is placed on probationary observation. Protected coitus while not harmful to the patient, should be restricted to the periods when he is under treatment control with an arsenical. The question of marriage cannot be determined without reference to the clinical course of the case, the tendency to relapse, the reactions of the prospective marital partner, who should be fully informed of the facts, and so on. In general, delay in marriage should be sought by every possible means for time is a vital element in reducing risk of infection in syphilis. Whether or not a nitritoid crisis will occur with the resumption of nearsphenamine treatment it is impossible to say. If the injections are given very slowly, the solution properly prepared, and the patient in a quiet and undisturbed frame of mind the risk of recurrence of nitritoid reactions will be greatly reduced.

RHEUMATIC CARDITIS

To the Editor—I have under my care a man aged 32 single who in his early youth was nicknamed Dragg by his companions because of apparent lack of physical activity. His parents inform me that he was never active. He was rather a sickly child. Six years ago he contracted syphilis which remained untreated. Last December he noted a persistent swelling of his ankles and consulted a nearby physician who gave him a 6 ounce bottle of tincture of digitalis and told him not to worry. His condition gradually became worse. Edema became more extensive and vesicles developed. He consulted other physicians and eventually had a goodly collection of digitalis in its various forms. I first saw the patient last April. He was hysterical. His last physician told him to go home and die as there was no further hope. Examination revealed marked dyspnea, severe cyanosis, massive edema of the lower extremities, a distended abdomen and bilateral hydrothorax. The heart was markedly enlarged and displaced downward. The apex beat was visible in the mammary line below the costal margin. There was complete obliteration of the heart beats. Systolic and diastolic murmurs were audible at the apex and the base. The heart action was strong forceful and rapid (110). There was no irregularity. The heart was trying hard to keep going. Other observations of significance were a 4+ Wassermann reaction and a mouthful of decayed and abscessed teeth. The right side of the mandible was necrotic as the result of tension of an abscess from the molars. There was no osteomyelitis. Immediate relief measures were instituted. Surgical drainage of both legs relieved the congestion of the extremities but failed to diminish the abdominal distention. Abdominal paracentesis was necessary and considerable fluid (serous) was removed. At the earliest opportune time all the abscessed teeth were removed together with some necrotic jaw bone. Antisyphilitic therapy was instituted. At present the Wassermann reaction is negative. During all this time the patient has continued to fill up so that it is necessary to perform an abdominal paracentesis about every two or three weeks. Digitalization has been tried on several occasions but the heart will not respond perhaps because of too much digitalis during the earlier treatments. I have abandoned this measure of therapy for the present. Several days ago I began to discern an indistinct rather muffled systolic beat at the apex. This was not present at any previous examinations. Percussing the heart's outline also revealed a slight diminution in size. My early diagnosis of the case was a specific endocarditis and myocarditis. Now I am beginning to believe that there was no endocarditis but that the murmurs were secondary to the extreme dilatation. If a way existed whereby I could strengthen the heart wall and decrease the size of the heart the valves would be brought closer together with resultant increased compensation. Your comments and suggestions in the treatment of this case will be greatly appreciated.

L E DENKE MD Mercedosia Ill

ANSWER—It is probable that the heart condition present is the result of a rheumatic carditis and not of syphilis, although a syphilitic basis is remotely possible. The fact that the patient was inactive as a child and "sickly" is suggestive of a rheumatic fever, even without the history of joint symptoms. Cases of rheumatic fever characterized by only "minor manifestations" are more frequent than has been realized. Vinberg has recently called attention to this group characterized by only indefinite symptoms. The high degree of passive congestion would be much more probable with a rheumatic lesion than with a syphilitic lesion.

One should consider the possibility that the heart shows the valvular changes consequent on a rheumatic carditis, with an adhesive pericarditis, and possibly either a Pick cirrhosis, or a cardiac cirrhosis.

Digitalis is of value in a normal rhythm frequently enough to warrant its trial. In many cases it is not of value and may do harm by decreasing the volume output. In this case it has apparently been given at least an adequate trial.

It is stated that the pulse is regular and the rate 110. The question arises as to the possibility of an auricular flutter being present. If auricular flutter is present the rate will show a noticeable constancy and will not change on change of posture or exertion, or it may be exactly double. Should auricular flutter be present, digitalis should be given in full dosage in an attempt to change the rhythm to an auricular fibrillation. If fibrillation does occur, the digitalis should be discontinued temporarily. In some cases the rhythm may return to normal and no digitalis may be necessary. If the auricular fibrillation persists, it should be controlled by resuming the use of digitalis. Should auricular flutter be present and the digitalis not alter the rhythm, the use of digitalis will at least increase the degree of block and slow the heart, although this may not result in any clinical improvement.

It is suggested that the patient be given ammonium nitrate, 2 Gm, four times a day, and from 1 to 2 cc of salyrgan every third day. On the second day after the salyrgan, a saline cathartic will help to eliminate the mercury compounds re-excreted into the bowels and will remove further fluids. The patient should be on a salt-free and preferably neutral diet, and a moderately limited fluid intake. One of the purine-base diuretics, such as caffeine, theobromine or theophylline compounds, may be tried.

It is probable that the anatomic changes in the heart are permanent. In any case they will take care of themselves with rest and time and there is no direct medication possible or advisable.

THINNING OF FINGER NAILS WITH PURPURA BENEATH

To the Editor—A white woman aged 24, a school teacher, has had a progressive thinning of the nails for the past three years. Growth is apparently normal as to length. There have been no symptoms until the past two weeks when 0.2 cm dark areas developed under the nails these spots being exceedingly painful. Routine physical and laboratory work has given negative results. Kindly omit name. M D Wisconsin

ANSWER—Thinning of the nails is usually due to some slight disturbance of the general health, though it might in some cases result from local interference with nutrition. Dark spots under the nails are commonly the evidence of petechial hemorrhage, which sometimes is seen nowhere else. It may be due to any one or more of the many causes of purpura, of which only those in which other symptoms might be absent need be considered here.

1 Trauma may be ruled out, for it would be indeed unlikely to cause many very small spots of approximately equal size.

2 Are the blood platelets normal in number? If below 100,000 a thrombocytopenic form of purpura may be suspected, such as morbus maculosus of Werlhof, lymphatic leukemia, splenic anemia or pernicious anemia.

3 Are coagulation and bleeding time normal? If not, the toxic condition due to liver disease should be considered.

4 What is the condition of the gums? Is mild scurvy possible?

5 Has the patient taken any drug liable to cause petechial hemorrhage, such as antipyrine, iodine, quinine, mercury, the salicylates, ergot, potassium chlorate or hyoscynamus, arsenphenamine gold salts or chloral hydrate? Has she received any injections of foreign protein lately?

6 Is she sensitized to any food? Purpura due to sensitization to wheat and eggs has been recorded.

7 Is there a possibility of focal infection, particularly endocarditis?

8 Hemorrhages under the nails have been observed in the early stage of Raynaud's disease, but this should be shown by paleness and coldness of the fingers with pain, followed by cyanosis, in attacks brought on by exposure to cold.

9 Reports are found in the literature of hemorrhages under the finger nails of a woman who suffered with dysmenorrhea, the spots appearing at the menstrual periods, and of a few idiopathic cases.

On transillumination of the finger, hemorrhages appear as dark spots.

Metastatic tumors are rarely seen under the nails. Melanomas would appear bluish. Syphilitic papules under the nails have been known to be hemorrhagic, but papules as small as these would be follicular secondary syphilids and other skin or mucous membrane lesions as well as positive Wassermann and Kahn reactions would be inevitable.

Treatment depends on the diagnosis. If petechiae, the pain is caused in all probability by pressure and can be relieved by drilling a small hole through the nail at each spot and then using surgical precautions against infection. Rest in bed

general exposures to ultraviolet rays, calcium therapy if jaundice is present, and autogenous vaccine from a focus of infection if such is found, may be beneficial. If sensitization is suspected, diet should correct the condition and it should recur on resumption of the guilty food. Suspension of injurious medication should give prompt relief except perhaps in the case of iodine, the effect of which may wear off slowly. Injections of whole blood or blood serum, or repeated small transfusions may be considered advisable. Iron, arsenic, ergot, the salicylates or quinine may be used as indicated, but only after they can be excluded as etiologic agents.

DERMATITIS HERPETIFORMIS IN VACCINATION

To the Editor—A woman aged 20 was vaccinated for smallpox on the right thigh seven years ago. Every winter since then she has had a recurrence of a pustule at the site of the vaccination accompanied by small pustules in the surrounding area and intense itching. Later there is scab formation and the lesion gives the appearance of a typical vaccination. The lesion usually persists throughout the winter months and clears up the following spring. Are there similar cases on record? Please suggest etiology and treatment. Kindly omit name.

M D Kentucky

ANSWER—The description leads one to picture fairly good sized pustules on nonreddened skin, and therefore not a simple dermatitis. Vesicular and bullous eruptions following vaccination have been noted by many observers. They occur in children or adults without regard to sex and last from months to a number of years. Most of them have been reported as dermatitis herpetiformis, although some cases of erythema multiforme and some of pemphigus have been recorded. These three diseases are related and the etiology in all of them is obscure.

The case described is not clearly any one of these three but may be a mild, atypical example. If eosinophils are numerous in the contents of the pustule or in the differential count of the white blood cells, if the eruption is cleared up by solution of potassium arsenite pushed to the physiologic limit, or if a 50 per cent ointment of potassium iodide applied over night to an area in which the eruption has cleared up produces a recurrence, the probability of its relation to this group of diseases is increased. Even though the internal administration of arsenic clears up the eruption, it is advisable to keep it for an emergency, because the danger of pigmentation and arsenical keratoses, which sometimes end as malignant epithelioma, is too great to warrant long continued use of the drug for so slight a disorder. Applications of sulphur either as ointment, 5 or 10 per cent, or as a lotion containing 1 per cent sulphurated potassa in water may alleviate the itching, or it may be checked better by opening the pustules under surgical precautions. Ultraviolet rays on the affected area strong enough to cause a decided erythema often benefit the eruption. Mild foreign protein therapy may be tried, as intramuscular injections of the patient's own blood, from 5 to 20 cc every fifth day for five doses. Vaccines may be made from the organisms isolated from the patient's stool, tested to determine which ones cause reactions in the patient, and these chosen for therapeutic use. Such eruptions yield but slowly at the best.

TRANSMISSION OF SYPHILIS BY HYPODERMIC NEEDLE

To the Editor—Another doctor made a Wassermann test on my left arm for insurance with a dirty needle and hand without sterilizing the needle, my arm or his hand. All that he did was to take the hypodermic syringe from a dirty medicine case with unclean hands and rub my arm with his dirty fingers making two attempts before getting into the right vein. After drawing blood he cleansed the needle and hypodermic syringe in cold water and put it back in the case. How long can a needle remain infected for syphilis if any was on it from previous case? Kindly omit name.

M D, Michigan

ANSWER—If the outside surface of the needle, when introduced, was and had been completely dry for a period in excess, say, of thirty minutes, the presumption is that spirochetes, at least on the outer surface of the needle, would have been destroyed. The problem arises with the bore of the needle and its content. In this case since the needle was evidently patent at the time the blood was drawn, the presumption is that it contained no clot or blood serum from the previous patient. Pertinent observations suggesting the possible state of affairs in the bore of the needle are these:

In order to make the transmission of syphilis at all likely, the person from whom the last preceding blood was drawn would have to be in the spirochetemic stage of the disease. While this cannot be exactly defined, it might be estimated as covering the first two years of the infection, with especial emphasis on the period of the primary lesion and secondary eruption. The bore of the needle except for the fact that the needle is made of metal instead of glass, approximates the con-

dition of anaerobiosis in the studies of Finger and Mahoney and Bryant, who have demonstrated the prolonged viability of *Spirochaeta pallida* in secretions from the primary lesions when contained in sealed capillary tubes. Contact of these secretions with metal, however, can be expected to have a marked, though unknown, destructive effect on the organism. Gaston and Commandon showed that *Spirochaeta pallida* was still recoverable from the edges of glass tumblers, washed in cold water, thirty minutes after washing. Zinsser and Hopkins found that the spirochetes in dark-field preparations at room temperature and exposed to daylight lived for approximately eleven and one-half hours, and that this was also approximately the life of the organism in secretions contained in moist handkerchiefs. Whether or not the organism remains infective for this entire period is not known. One might estimate, then, that in a needle through which spirochete-containing blood had passed, cleansed only with cold water, and remaining moist the viability of the organism, disregarding the metal wall of the container, might range from thirty minutes to eleven hours. Under favorable conditions, such as the presence of body secretions, strict anaerobiosis, protection from light, and optimal temperature, *Spirochaeta pallida* has been recognizable morphologically and its motility has been preserved for as long as fifty-eight days (Lacy and Haythorne). It is however highly improbable that such conditions would be reduplicated in the bore of a hypodermic needle under the usage described in this question.

As to whether it would be necessary actually to inject material from the supposedly infected needle bore into the subcutaneous tissues of the blood stream, no clear cut answer can be given, but Brown and Pearce have shown that the mere passing of an infected needle (external surface infected of course) through the testicle of a relatively resistant animal such as the rabbit is sufficient to produce infection without the actual injection of material.

CHRONIC SINUSITIS

To the Editor—I am suffering from a chronic condition of the nose and throat dating from an attack of scarlet fever in March 1932. Previous to that time I practically never had a cold, sore throat or any other form of respiratory disease. I had a well developed form of scarlet fever the acute symptoms lasting for about eight or nine days. Following acute symptoms I began to have a profuse thick purulent discharge from the nasal passages. There was no other complication. I continued to have a rather profuse purulent discharge for about two months after which it still continued in a more watery form to a lesser or greater degree varying at intervals up to this time. After about four or five months I began to be plagued by a constant gathering in my throat necessitating a constant clearing of this in order to be able to carry on a conversation. At times the condition is such as to make contact with my patients quite embarrassing because of inability to carry on an uninterrupted conversation. There seems to be a constant discharge in the nasopharynx which seeps down into the laryngeal region and interferes with speech. For the first three or four months no medication was used but since then various forms of ephedrine in oil neosilvol and so on have been used with apparently no benefit. Last March I began the use of Lilly's autolytate vaccine containing the lysed bodies of bacteria normally present in the respiratory tract. Marked improvement resulted for about four months which may have been affected by the summer weather. With the sudden changes of temperature this fall the condition has been worse than formerly at times and has been little affected by medication such as ephedrine antiseptics or the autolytate vaccine. I have consulted an eye ear nose and throat specialist who states that it is a chronic catarrhal infectious condition. He found some deviation of the septum and swelling of the turbinates and mucous membrane but only moderate obstruction to breathing. He states that the sinuses and tonsils are normal but suggests that possibly removal of the tonsils or cauterization of the turbinates might have a beneficial effect but that he doesn't know. I am a general practitioner in a city of 2000 population in a farming community and am 29 years of age. I have always had good general health. I smoked a pipe quite steadily until I discovered that smoking intensified the condition, when I quit it entirely. Could you suggest some method of treatment that would control this condition or cure it? I find that there are many patients in my practice in this locality who suffer in a similar manner and who I find improve quite remarkably well with the use of the autolytate vaccine. Please omit name and address. M D Wisconsin

ANSWER—No answer can be given until it is absolutely certain that no suppurative sinusitis is present. The history of a purulent nasal discharge in the course of a scarlet fever is highly suggestive of nasal sinusitis. Neither the appearance of the nose on occasional examination nor roentgen examination alone is sufficient to rule out the presence of pus in the accessory nasal cavities. Both antrums should be punctured and diagnostic lavage performed several times if necessary. The rhinopharynx should be examined carefully with a view to determining the condition of affairs in the sphenoid sinuses. On occasion without any operative intervention it is possible to perform diagnostic lavage of the sphenoid sinuses. Until it is determined by these methods and until observation of the ethmoid and frontal sinus areas gives satisfactory evidence of

the absence of a purulent process, no diagnosis of a catarrhal condition should be made. In the absence of pus, judicious cauterization of the inferior turbinates may be beneficial. Vaccines are occasionally helpful but their benefits are probably not specific and are due in all likelihood to a foreign protein shock mechanism. The removal of the tonsils in this particular instance will probably not help the nasal condition.

PIMENTO PEPPERS

To the Editor—With interest I have read the editorial on Pimento Peppers in THE JOURNAL Dec 16 1933. I am now asking for information regarding authority for the name. The Funk & Wagnalls Standard Dictionary states that pimenta or pimento is the allspice of the tropics. It also gives pimiento. In this country we have the pimiento or sweet pepper if it may be so called, but we do not apply the name pepper to pimiento which I take it is the fruit which your editorial means. To say pimiento pepper is superfluous. One might say Rio Grande river in the same way. When in markets we speak of or call for pimentos. We use this fruit freely and I am glad to have the information given in the article in THE JOURNAL.

KNOX BACON M D, San Diego Calif

ANSWER—Two points should be made clear: the justification for the use of the word 'pimiento' instead of 'pimienta' and the authority for the term 'pimiento pepper'. The distinction between 'pimiento' and 'pimienta' has been frequently made, the former meaning the sweet pepper and the latter referring to allspice, the dried fruit of *Pimenta officinalis* or Jamaica pepper. Furthermore in the Weekly News Letter of the U S Department of Agriculture dated July 21, 1915, it is stated that the sweet pepper, also called the "pimiento" is incorrectly referred to as pimiento. On the other hand in the Century Dictionary and Cyclopedia appears the following: Pimiento (also pimienta). Sp. pimiento, the pepper plant, capsicum, pimienta, the fruit of this plant applied also to Pimenta officinalis Jamaica pepper (allspice, the berry of Pimenta officinalis). Furthermore, Mr Vizetelly, the distinguished lexicographer of Funk and Wagnalls, states "Our pimiento however, is one of two things (1) allspice, (2) capsicum." Artemus Ward in the 'Encyclopedia of Food' gives "Pimiento or Pimento or Pimienta is large fruited Spanish capsicum yielding, when dried Spanish paprika. It appears, therefore, that the distinction between 'pimiento' and 'pimento' is gradually disappearing.

Pimention is large pepper otherwise Cayenne or red pepper', piment is pepper, specifically black pepper', pimiento is 'capsicum or pepper—as the fruit of the pepper'. In view of the confusion between pimiento (allspice) and pimento (sweet pepper) it makes for clarity to designate the Spanish sweet pepper as the pimiento pepper. From a practical horticultural point of view there are hot peppers, mild peppers and the mild sweet peppers containing more sugar, which have been referred to as pimento peppers. In the U S Department of Agriculture, Departmental Bulletin 669 dated 1918, on pages 26, 27, is mentioned a study of "the influence of pimiento peppers upon the keeping qualities of pimiento cream cheese." Also in the Farmers Bulletin 960, 1918 page 13 it is stated that "pimiento peppers cost about 40 cents a pound." In the current catalogues of each of two well known and reliable seed houses the term 'pimiento peppers' is used to distinguish this fruit from the other kinds of peppers offered for sale. The term 'pimiento' or 'pimienta' has become commonly used as a designation of variety among practical horticulturists.

PARACENTESIS VERSUS SPONTANEOUS PERFORATION IN OTITIS MEDIA

To the Editor—I should like to know the present consensus regarding paracentesis of the ear drum versus spontaneous perforation. Does the delay in waiting for resolution and absorption and the permission of a spontaneous rupture resultant therefrom compensate for the often needless paracentesis of a drum and the resultant danger that infection will follow that procedure? I am aware that an incised drum may heal more nicely than a torn one but does this difference in healing compensate for the possibility that resolution may take place? Just what harm is there in the laissez faire policy of waiting for perforation? The opinion seems to exist of the hasty and promiscuous opening of ear drums with the need less exposing of the middle ear to infection. I should like to know the consensus among pediatricians and general practitioners as well as otologists. Please omit name. M D New York

ANSWER—There is still considerable difference of opinion with reference to paracentesis of the drum membrane as opposed to spontaneous perforation. The Vienna school was long of the opinion that a myringotomy was preferable to spontaneous rupture. It would seem that the same principle should be applied in cases of otitis media that is used when there is a collection of fluid under pressure in any other part of the body.

In other words, it is preferable to relieve pressure by well planned opening rather than permit the spontaneous rupture, which may destroy a considerable portion of the drum membrane and lead to a permanent perforation, whereas a fine incision or puncture with a sharp instrument usually heals rapidly without damage to the drum membrane.

Furthermore, it is a fair assumption that an early evacuation or the promotion of escape of fluid would carry with it less tendency to injury to tissues in the middle ear and mastoid antrum than the damage that often occurs when waiting for a spontaneous rupture, especially through a thickened drum membrane.

While we are not aware of any statistics which definitely prove that cases of otitis media in which early myringotomy was performed show fewer instances of mastoiditis than those in which spontaneous rupture was awaited, we feel, in line with the principles stated, that it is a better policy to puncture the drum membrane when definite signs of pressure from contained fluid are present.

TOXICITY OF SHOE DYE PREPARATIONS

To the Editor—Can you give me any information regarding a preparation called Checker Shoe Dye Primer manufactured by D F Brown and Company Boston? A shoemaker since using this preparation to prepare shoes for dyeing has noticed a diffuse erythema on both hands. I should appreciate any information you can give me regarding the constituents of this product so that I may determine whether or not it is the cause of the trouble. Kindly omit name. MD Chicago

ANSWER—We have no specific information concerning the preparation mentioned. Without reference to any specific types of shoe dye or primer, it may be stated that all are believed to contain constituents capable of inducing skin lesions among some of the total number of those exposed.

Recent examinations have failed to disclose the presence of nitrobenzene in shoe dyes, even when the odor that is more or less characteristic of this substance was present. A widely used solvent for shoe dyes is orthodichlorobenzene. This is an irritant both to the skin and to mucous membranes.

Methyl alcohol, along with various other alcohols, is in some use in products of this type.

Aniline black, if used as the dye, may in itself constitute a skin irritant apart from any of the solvents mentioned.

UNDULANT FEVER

To the Editor—A man aged 36 married has been ill for the past two years. In December 1932 his condition became worse and in April 1933 he was forced to go to bed. He has lost 20 pounds (9 kg). His present weight is 155 pounds (70 kg). The patient is a tall blond with a phthisical chest and slightly stooped posture of typical neurasthenic type. The temperature has never been above 101 F. Hemoglobin is 55 per cent. The urine is negative for red blood cells pus or blood. The Wassermann reaction is negative. The tuberculin test is negative. A roentgenogram of the chest shows considerable peribronchial thickening around the hilar regions. The blood pressure is 108 systolic 70 diastolic. Examination of the heart lungs and abdomen grossly gives negative results. Blood agglutination shows positive for undulant fever in a dilution of 1:160. Treatment has consisted of iron in adequate dosage in the form of iron and ammonium citrate. The hemoglobin has risen to 78 per cent. Neocarsphenamine in 0.6 Gm doses was given four months ago at weekly intervals for six doses but was discontinued because of severe subjective symptoms. Three weeks later an Alcaligenes abortus vaccine or antigen was tried with almost complete remission for six weeks. This case has undoubtedly gone on for more than a year. Does undulant fever usually continue that long? I attribute the peribronchial density to the present infection. Am I right? Why has the temperature not gone above 101 F? In addition to the symptoms mentioned the patient has a mild conjunctivitis which has persisted and which was present before the administration of arsenic. Can you suggest any form of chemotherapy or specific therapy which I have not yet tried? The patient is particularly sensitive to intravenous medication for which reason I have not tried acriflavine or similar substances. Any suggestion as to further treatment would be greatly appreciated. Incidentally the patient's wife also has a positive blood agglutination and evidently had a mild form of the disease but has recovered. Please omit name and address. MD North Carolina

ANSWER—Many cases of undulant fever have been reported in which the disease has persisted for several years. The peribronchial thickening at the root of the lung may be due to the lymphadenitis that frequently accompanies this infection. In the low grade chronic infections it is not unusual for the temperature to exhibit mild fluctuations for many months. Many observers have found the Alcaligenes melitensis (abortus) vaccine an effective therapeutic measure. In the chronic cases larger doses may be required than are ordinarily used for acute or subacute cases. I F Huddleson Michigan State College, East Lansing Mich (*Am J Trop Med* 13:485 [Sept] 1933) has obtained good results with brucellin which apparently exerts a specific influence on the disease.

PSYCHIC REACTIONS TO MENSTRUATION

To the Editor—My patient is a friend of my family, a woman aged 30 married. She has one boy of 7. She had another child but it was born dead as the result of strangulation by the cord during delivery. She is of rather a nervous type intelligent and socially active. She complains of frigidity. She was examined by the most efficient gynecologists but they found her in normal condition. All the tests for the blood and urine were made by an expert including a Wassermann test. A metabolism test was negative. She has a blood pressure of 140 systolic 70 diastolic. Her mother died of arteriosclerosis and hemiplegia. Her sisters also have a blood pressure of 140 systolic 70 diastolic. There is a tendency in the family toward nervous conditions but no insanity or severe nervous diseases. Otherwise the family history is negative. About three days before menstruation the patient is seized with a peculiar attack. She complains of cold finger tips and numbness in both arms the numbness extending rapidly to her back. Her upper lip gets numb and then she commences to cry severely for an hour insisting that she is going to die as she is numb all over. She usually faints during this attack but she has no convulsion. A hypodermic injection of morphine or lately sodium amytal and bromides relieve this attack within a few days. The numbness disappears within twenty-four hours. Nervousness and weakness persist for days until she gets her scanty menstruation and then she is totally relieved. Kindly let me know what you could suggest in this condition. Please omit name. MD, Pennsylvania

ANSWER—The symptoms enumerated here are most likely vasomotor responses to a hormonal stimulus. However, there is undoubtedly a large psychic factor involved. There is visible nervousness in the patient and a family history of the same condition. The slight elevation in blood pressure is probably part of the same picture. An effort should be made to have the patient lead a calmer existence. Special emphasis should be laid on giving up some of the most worrisome of the social activities, particularly if they include club work of a character demanding much time, effort and worry. Sedatives, such as the bromides, sodium amytal, elixir of phenobarbital and others should be given in large doses beginning just before the time the symptoms are expected. Furthermore, an effort should be made to have the patient do some interesting work around this time if possible. Morphine should be avoided, but as much psychotherapy as is deemed wise should be used.

RIGHT AND LEFT HANDEDNESS

To the Editor—Please inform me if it is possible to tell definitely whether a child is right or left handed. The child in question 6 years of age appears to be ambidextrous but is very clumsy with either hand. His teacher will not promote him because his writing and drawing are very poor though he is above average physically and mentally in every other respect. His right eye is the dominant eye with normal vision in both eyes. In his home the child has been permitted to use either hand though gently encouraged to use his right hand. He does not stammer or show any peculiarities except at times a suggestion of mirror writing. Both of his parents are right handed. I have been unable to obtain definite information on this subject. Please omit name if published. MD Texas

ANSWER—Tests of handedness consist of observing the use of the hands in various technical procedures, such as throwing a ball or using tools. Reports of such studies, with references to the literature, will be found in an article by Quman in the *Archives of Neurology and Psychiatry* (24:35 [July] 1930) and further information can doubtless be secured by writing to the Speech Clinic, Iowa State Psychopathic Hospital, Iowa City.

VENEREAL PROPHYLAXIS

To the Editor—What are the prophylactic instructions given and the procedure recommended to the personnel of the United States Army and Navy to prevent gonorrhea and syphilis? Are there any other methods superior to these? Please omit name and address. MD Florida

ANSWER—The technic of prophylaxis for the male is as follows. If possible, the patient is not allowed to administer the treatment to himself. He is made to urinate. He is provided with a basin of warm water and a gauze wipe, with which he washes the genitals thoroughly while liquid green soap is dropped on the penis. The washing to be done thoroughly, should consume about ten minutes and should include the penis, scrotum pubis and the adjacent areas of the thighs. Especial care should be observed in washing thoroughly the folds of the frenum and foreskin. After washing, the parts should be dried thoroughly. The washing with soap and water is important, soap is the only part of the treatment effective against chancroid, and it is also of value as a destroyer of the organism of syphilis.

The next step is the injection of 4 cc (1 drachm) of a freshly made up 2 per cent solution of strong silver protein (or a 10 per cent solution of mild silver protein) into the urethra by

the physician. The patient then holds the meatus firmly between the thumb and forefinger for five minutes, from time to time allowing a drop to escape from the meatus, so that all parts of the urethra are in contact with the solution. At the end of five minutes the silver protein is allowed to escape, without pressure or stripping, so that a few drops remain. From 2 to 4 Gm (one-half to 1 drachm) of 33 per cent calomel ointment is next rubbed thoroughly by the patient, under the observation of the physician, into all parts of the penis for five minutes, special attention being paid to the retracted prepuce, the frenum and the glans. The scrotum also should be rubbed with ointment. The genitalia are then wrapped in toilet paper or waxed paper to protect the clothes, and the patient is instructed not to urinate for four or five hours.

TRANSFUSION OF MATERNAL OR PATERNAL BLOOD IN NEW BORN

To the Editor—The question has arisen whether maternal or paternal blood is preferable in the treatment of hemorrhage in the new born. I am under the impression that there is a hormone in the parturient woman which diminishes the clotting time of the blood. Kindly omit name.

MD Arkansas

ANSWER—So far as now known there is no hormone in the blood of the parturient woman that reduces the clotting time of the blood of the new-born. So far as the properties of blood in stopping hemorrhage is concerned, maternal and paternal blood under normal conditions may be assumed to have the same effect, generally speaking.

WEAKNESS OF KNEES IN OLD AGE

To the Editor—Will you kindly tell me what might be the cause of weakness of the knees in a man about 72 years of age? His legs give way under him involuntarily while standing still. The blood Wassermann reaction is negative and physically he appears to be all right. Kindly omit name.

MD, California

ANSWER—With so few data it is of course impossible to offer any opinion in this particular case. On the organic side, such giving way may be due to temporary ischemia in the spinal cord due to intermittent claudication of blood vessels within the cord. The most common functional cause is a fear of falling, so-called astasia-abasia. Unless the patient is obviously psychoneurotic, it would be more reasonable to look for an organic cause at his age.

RESULTS FROM ONE-SIDED SECTION OF VAGUS

To the Editor—A man at present 40 years of age was wounded in the head about 1917. A gunshot entered below the left eye and emerged in the region of the left angle of the jaw, lodging in the left scapular region from which it was shortly afterward removed. About a month later an aneurysm developed in the internal jugular vein at the point where it emerged from the skull. The internal carotid artery communicated with the sac (arteriovenous aneurysm). The carotid artery was ligated subsequently at operation. Both vagus and hypoglossal nerves were found eroded through by the aneurysm or owing to the effect of the original wound. Naturally such an extensive injury created a profound constitutional disturbance. The patient had the usual paralysis of the face and the glottis some difficulty of deglutition for a while and drooping of the eyelids, but almost complete recovery of these functions has occurred. However since that time more remote effects seem to be increasing in severity. He has constant troublesome constipation and has to use cathartics continually. His accompanying indigestion is amenable to neither diet nor drugs. Recurrent severe headaches are becoming more frequent. Associated with these symptoms is a feeling of general weakness. Any exertion leaves him weak and tired so that he is unable to do even the lightest labor on his farm. A recent examination shows his heart enlarged with a systolic murmur although no cyanosis or dyspnea. What are the late results of one-sided section of the vagus? Is it not possible that the gastrointestinal and cardiac complaints may be due to a change in tone of the muscular walls of the bowels and heart respectively? At any rate that is my theory. As the man is a deserving case and I am convinced there is no question of malingering I have advanced this theory to the board of pension commissioners for Canada who refuse to act on it. Previous suggestive history is negative. GEORGE J. CAMERON MD LeRoy Sask. Canada.

ANSWER—Symptoms produced by destruction of the vagus would have appeared early and later decreased in severity. There may be some independent cardiac or gastro-intestinal ailment that accounts for the late visceral symptoms. True, there is evidence to show that unilateral lesions of the vagus may cause visceral symptoms. Thus, Purves Stewart in his "Diagnosis of Nervous Diseases" says "Gastric symptoms have also been observed even in unilateral cases, such as gastric dilation, vomiting, gastric pain and loss of sensations of hunger and thirst. The oculocardiac reflex is abolished on the affected

side, thus is an important evidence of a lesion of the vagus trunk." Russell Brain in his "Diseases of the Nervous System," 1933, says "Little is known concerning the effects of lesions of the vagus upon its visceral functions." Since the man has a claim for compensation, it is of course possible that a functional neurosis may enter in.

USE OF HIGH CHOLESTEROL DIET IN RELATION TO SCLEROSIS

To the Editor—In *Queries and Minor Notes* in THE JOURNAL, January 13, page 150 the question is asked whether a minimum of cholesterol in the diet may be beneficial in retarding the advance of sclerosis. The answer conveys a little too much of the impression that a high cholesterol diet plays little part in the development of arteriosclerosis in man.

Ever since Anitschkow in 1912 produced atherosclerosis in the aorta of rabbits with cholesterol feedings, pathologists and clinicians have wondered whether or not high fatty diets may cause arteriosclerosis in man. Saltykow, Wacker and Hueck, Aschoff and others confirmed the observations of Anitschkow in the rabbit with cholesterol feedings (milk cream, yolk of eggs, brain substance, solution of cholesterol in oil). Cholesterol feeding experiments demonstrated that it is possible to produce fatty deposits in the intima of the blood vessels of the dog (Adler), white rat (Chafetz) and guinea pig (Anitschkow). Aschoff thinks that the fatty deposits in the intima of the aorta of nursing infants are derived from the fatty substances found in the milk. It has been shown that the experimental atherosclerosis and the suckling atherosclerosis disappear if the fatty diets are stopped. The longer the fatty diets are continued, the more marked the blood vessel changes and the less chance for return of the blood vessel wall to normal after stopping the fatty diet. The addition of bile acids to the fatty diet favors the deposit of fat in experimental animals.

The common occurrence of arteriosclerosis in diabetic patients with high blood cholesterol and acidosis has long been known. Recently Shephardson investigated fifty young diabetic patients and found that paralleling a reduction in lipemia the incidence of arteriosclerosis was greatly reduced. Shephardson considers an altered fat metabolism the important factor for the development of vascular disease in association with diabetes.

In lipid nephrosis the blood cholesterol is very high but still there are no striking deposits of fat in the intima of the blood vessels. It would seem therefore that something other than a high lipid content of the blood plasma favors a lipoidosis of the intima. Schmidtman and Huttich teach that in man the blood vessel walls become more acid with age and that this acidity is at least one factor favoring a lipoidosis of the intima. In his last monograph on arteriosclerosis (1930) Aschoff considers arteriosclerosis a wearing out and nutritional problem. Aschoff believes that with age and hard work the muscle and elastic tissues of the blood vessel wall are replaced with fibrous tissue. Through this change in the consistency of the blood vessel wall Aschoff thinks that the intima can now more readily imbibe the fat presented to it by the blood stream.

Chamberlain states that the blood cholesterol is raised in arteriosclerosis but he does not know whether to regard this as cause or effect. Gechtman and Slanskaya found an excess of cholesterol and calcium in the blood of arteriosclerotic patients and recommended therefore, a diet low in these substances.

So much for the consideration of the fat in the diet in arteriosclerosis. I will now in a sketchy manner recall some of the actions of vitamin D in the diet.

Laech found that the oral administration of ergosterol to adults increased the serum calcium and cholesterol in most cases. Mancke produced calcification and dilatation of the aorta in rabbits by feeding from 1 to 50 mg of viosterol daily, the degree of aortic involvement depending on the duration of administration. Similar results to those of Mancke were obtained in rabbits by Huckel and Wenzel with doses of viosterol ranging from 9 to 700 mg. In from one to three weeks, marked calcifications were noted in the media of the blood vessels with necrosed areas in the overlying intima. Nine milligrams of viosterol damaged the media of the kidney arterioles. King and Hall produced hypercalcemia in chickens using massive doses of viosterol. Besides showing the symptoms of hypercalcemia (anorexia, loss of weight, emaciation, death) the kidneys of these chickens contained heavy calcium deposits.

It has been thought that ultraviolet radiation and sunlight by acting on the sebaceous matter of the skin or the fatty substances in the blood protect and cure rickets possibly through the development of vitamin D or its equivalent. Windaus (Nobel prize winner for showing the relations of irradiated sterols to vitamin D) has even gone so far as to suggest that excessive exposure to sunlight might produce so much viosterol in the blood that calcifications are formed in the media of the blood vessels.

In a recent (1932) study of the alimentary factors in arteriosclerosis Raab has summarized the main evidences as follows:

- 1 The administration of cholesterol in animal experiments leads to a lipoidosis of the intima.
- 2 The administration of vitamin D in animal experiments leads to a calcinosis of the media.
- 3 Lipoidosis of the intima and calcinosis of the media represent the basic changes in arteriosclerosis in man.
- 4 Cholesterol and vitamin D are abundantly present in the much used foods such as egg yolk, cream, butter, milk, animal fats and cod liver oil. The suggestion is given that abundant and long continued use of these foods may produce arteriosclerosis in man.

Book Notices

Modern Clinical Psychiatry By Arthur P. Noyes, M.D., Superintendent of State Hospital for Mental Diseases, Howard, Rhode Island. Cloth. Price \$4.50. Pp. 485. Philadelphia & London: W. B. Saunders Company, 1934.

Textbooks on psychiatry will always be susceptible to much criticism, because of the inconstant nature of the subject. The present work brings into the field a textbook that is well written, simple and substantial. It has the usual introductory chapters describing mental mechanisms and motivations, and these are less conservative than those expressed in previous books but more conservative than are the opinions of psychiatrists in general. The tenor of the work is along conventional state hospital lines rather than those of dynamic psychiatry found among teachers, mental hygienists and private practitioners. The classification of mental disorders adopted by the American Psychiatric Association is the determinant of the chapter arrangement. Each psychosis is dealt with systematically, only essential information is given, and there are the usual illustrative case histories. Some of the features that make this book different from former textbooks are a fair bibliography at the end of each chapter, a practical attitude toward therapy, a chapter on the psychobiologic constitution, and the modern attitude toward mechanisms. On the other hand there is a certain looseness of terminology, quotations are made in the text without references in the bibliography, and there is no glossary. The chapters treating of neuroses, psychopathic constitution, mental deficiency and kindred subjects that confront the practitioner—particularly one who does not practice in a state hospital—are too short and they do not present enough aspects of these subjects to introduce them adequately to the student of mental hygiene and allied fields. This work offers little to the practitioner, but teachers of psychiatry who have been looking for a simple understandable textbook may find this to be what they have wanted.

Causal Factors in Tuberculosis. A Report of an Investigation into the Incidence of Tuberculosis in Certain Tyneside Districts By F. C. S. Bradbury, M.D., D.P.H., Medical Commissioner for Tyneside Inquiry. Paper. Price 2/- Pp. 126. London: National Association for the Prevention of Tuberculosis [n.d.]

Any decision of the causal factors in tuberculosis must take into account the fact that tubercle bacilli are the true causative agents, hence the discussion must necessarily devolve into a consideration of the conditions that affect the dissemination of the bacilli. The contrast in the incidence of tuberculosis in two towns in the same county was the impetus that started the present investigation. Jarrow and Blaydon in the county of Durham have a population of 32,000, but the tuberculosis morbidity of Jarrow is much higher than that of Blaydon. Overcrowding is given initial importance. This is a factor that has long been recognized as of importance in the transmission of tuberculosis, yet it cannot be overstressed as long as undiagnosed cases of tuberculosis and carriers of tubercle bacilli are free to infect their associates. "Intimate and prolonged" contact carries a definite meaning to all workers in tuberculosis and overcrowding in tenement buildings insures that just such conditions will be true of the associates of every open case of tuberculosis. From the standpoint of undernourishment, Bradbury concluded that an insufficiency of fresh milk is more important than shortage of other foods in predisposition to tuberculosis. He found some evidence that the incidence of tuberculosis is relatively higher in households where the mother of the family married at an early age, but he is inclined to believe that poverty is more common in such homes and that it is the more important factor. The greater prevalence of tuberculosis in families of large numbers is explained on the basis of more persons at risk when a case of tuberculosis exists in the family. He points out that poverty shows a marked statistical association with tuberculosis and that this association is greater than in case of most of the other factors studied. The chief results of poverty are overcrowding and undernourishment.

While he found a greater incidence of disease in adult males than in adult females the course of the disease was equally

serious in the two sexes. He found only a small proportion of deaths from nonpulmonary tuberculosis, but among those found there was an unusually high proportion from abdominal disease. This was true also among nonfatal cases. He believes that the limited use of fresh milk in Jarrow may be associated with the local peculiarities in the distribution of bovine and human infection and may be responsible for the small number of cases of bone and joint tuberculosis which occur in that area.

The factor of race in relation to tuberculosis is given considerable space. The author points out that there is more tuberculosis in Irish than in English families and that in Jarrow 14 per cent of the population is Irish, whereas in Blaydon the Irish constitute only 3.5 per cent of the population. He is of the opinion that the inferior environmental conditions of the Irish families does not adequately account for the greater prevalence of tuberculosis among them and offers relative lack of immunity as the explanation. These conclusions as to racial susceptibility or immunity do not tally with the more recent studies of the same factor in this country. As Dr. Bradbury points out, poverty and overcrowding are the important factors in morbidity rates, and stage of disease on diagnosis and efficacy of treatment as pointed out by racial investigators here are the important factors in mortality rates.

The Health and Turnover of Missionaries By William G. Lennox, A.M., Sc.D., M.D., Instructor in Neuropathology, Harvard Medical School, Boston. Published by the Advisory Committee, J. G. Vaughan, M.D., Chairman, E. M. Dodd, M.D., H. J. Tierling, M.D., and M. H. Ward, M.D., Cloth. Price 70 cents. Pp. 217 with 71 illustrations. New York: Foreign Missions Conference, 1933.

In recent years there has been a curtailment in the financial support and in the number of persons who volunteer for service as foreign missionaries. In 1928 the medical secretaries of four large American boards requested that an analysis of the data in their medical files be made so that their judgments might be based on scientific knowledge rather than on general impressions. The author, who was formerly a medical missionary, was engaged in this study more than two years. He was assisted by an advisory committee of physicians. There have been 75,000 workers, of whom 48,000 were women, in more than a century of Protestant missionary work. Only 25,000 of the total are still active. Of the 50,000 who have left the work, 10,000 died while actively engaged and 40,000 left in order to rest or to enter other employment. The death rate and the resignation rate among the women missionaries were greater than among the men. The average length of the period of service of these missionaries has been twelve and a half years. The average length of service of the married and single missionaries was 13.7 and 8.5 years, respectively. A study of 3,733 missionaries who left the work since the year 1900 shows that 46 per cent of them withdrew because of physical breakdown either of the missionary or of a member of the family on the field. Fifteen per cent of all persons leaving had proved to be misfits. Thirty-four per cent of those who left did so because of unavoidable circumstances. Missionaries have a high death rate from tropical diseases, drowning and violence. The illnesses that interfere with their work are due largely to neuroses and to epidemic diseases. From the study of these records it is estimated that in the next 10,000 years of missionary service (about the annual missionary enrolment of the North American Protestant missionary boards) there will be 168 missionaries lost to the service because of ill health, 82 because of death, and 103 because of being misfits. There will be, it is further estimated, 25 persons lost from smallpox, 13 from typhoid, 56 from dysentery and diarrhea, 37 from tuberculosis, and 104 from neurosis.

The rate of withdrawal of missionaries during the seventy-five years between 1840 and 1915, between 3 and 4 per cent, remained remarkably constant. In the five year period ended Jan. 1, 1930, the average yearly withdrawal rate was 5.74 per cent, but in the next two years it decreased again to 4.85 per cent. The rate of turnover of missionaries since the close of the World War for Protestant missionaries has been consistently upgrade. The death rates among missionaries have progressively declined. Thirty-five missionaries out of each thousand died annually during the period 1825 to 1829, and a hundred years later (1925 to 1929) only five out of each thousand missionaries died annually. The probable cause of death

was obtained by the author of 693 missionaries who died either on the field or within a year after leaving. Tropical diseases accounted for about one fifth of these deaths. While smallpox is widely distributed through the world, all deaths of missionaries from that cause reported occurred in China or India. Among the nontropical infections, the respiratory diseases were most important. A surprising number of missionaries have been drowned (2 per 10,000 for all adults). Drowning was nearly twice as deadly as dysentery.

The author analyzes various other data that are contained in the reports of these boards. The business of foreign missions is a major philanthropic venture. In 1923 there were 826 Protestant societies and committees in the United States, Canada, Great Britain and Europe for the furtherance of missionary work. These organizations at times have supported about 29,000 missionaries in foreign lands.

Nouveau Traité de Psychologie. Par Georges Dumas, professeur à la Sorbonne. Tome III. Les associations sensorimotrices. L'équilibre et l'orientation. L'expression des émotions. Les mimiques. Le langage. Avec la collaboration de André Ombredane, assistant près de la chaire de psychologie expérimentale à la Sorbonne. Cloth. Price 100 francs. Pp 462 with 155 illustrations. Paris: Librairie Félix Alcan 1933.

The third volume of this well known treatise deals with those psychic functions which are ordinarily called sensorimotor and among which are customarily included orientation, equilibrium, expression of emotion, mimicry and language. These differ from the primary sensory and motor functions in that they involve multiple sensory and motor pathways, which have already special functions, and impose on them secondary systematizations. The first section, dealing with equilibrium and orientation, is essentially a detailed summary of the work of the Magnus de Kleijn and Sherrington schools of neurophysiology. The discussion of the emotions begins with a historical account of the work of Spencer, Darwin, Duchenne and others, followed by a detailed description of the external expression of various preliminary and special emotions, with numerous illustrations. One may note the interesting analogy given by the author between the effects of stimulation of the facial nerve and the expression of joy, and the effects of paralysis of the nerve and the expression of sadness. The discussion of the mechanism of emotion follows largely the work of Cannon and Head. In the section on mimicry the author maintains his belief that the cerebral cortex is the original seat of the mimic reactions. The volume terminates with a discussion of language. Language is considered to be the totality of the gestures which the individuals of any collectivity use as signs. In the discussion of language, aphasic troubles are given much attention and the work of Marie, Hughlings Jackson and Head utilized at length. The author concludes that there are no innate or preformed cerebral centers for language any more than there are for dancing or swimming, but he admits that the effect of cerebral lesions on the function of language varies with their anatomic situations. This volume is better printed than the former, the proofs have evidently been carefully read. The discussion is well documented. The volume can be heartily recommended as an authoritative treatise on the sensorimotor functions.

Functional Affinities of Man, Monkeys and Apes. A Study of the Bearings of Physiology and Behaviour on the Taxonomy and Phylogeny of Lemurs, Monkeys, Apes and Man. By S. Zuckerman, M.A., D.Sc. MKCS Research Associate, Yale University. Cloth. Price \$3. Pp 203 with 24 illustrations. New York: Harcourt, Brace & Company 1933.

The subject matter of this book was originally prepared for a discussion on "Primates and Early Man," which took place at the meeting of the British Association for the Advancement of Science in 1932. Monkeys and apes were used as experimental subjects because they are suitable for the investigation of certain diseases or for the analysis of physiologic mechanisms. The evolution of man from the animal world can be traced by the correct classifications of the animals, the apes and the monkeys which most closely resemble him in structure. The author uses facts derived from physiologic and behavior experiments in arranging man, apes, monkeys and lemurs in a systematic series. He shows how the functional evidence supports the evidence of gross morphology. A taxonomic and phylogenetic survey is given of the results of experimental investigations on these animals. The author believes

that a study of the functional characteristics of the Primates from the comparative point of view would not only benefit taxonomy but reveal the gaps in our knowledge of functional differentiation. He endeavors to emphasize approaches to the question of primate phylogeny that have been seldom used and to indicate the proper place of functional investigations in the study of the classification and evolution of the Primates. There are a number of interesting pictures of apes, monkeys and lemurs.

Die Bluttransfusion. Von Prof. Dr. F. Oehlecker. Erweiterte Sonderausgabe der gleichbetiteltten Abhandlung im Handbuch der allgemeinen Hamatologie. Herausgegeben von Prof. Dr. Hans Hirschfeld und Dr. Anton Hittmair. Paper. Price 4 marks. Pp 87 with 43 illustrations. Berlin & Vienna: Urban & Schwarzenberg 1933.

An extensive experience with transfusion, both before and after the introduction of the modern serologic methods of grouping and compatibility, forms the basis for the author's quite definite ideas on various aspects of this subject. His main thesis is the hemolytic phenomenon, the reaction, in vivo, resulting from hemolysis of transfused red blood cells of incompatible donors. Descriptions are given of the clinical manifestations of the phenomenon and emphasis is placed on the efficacy of the biologic test. This test is performed by injecting a small amount of the donor's blood into the recipient's circulation and observing the recipient for a few moments. It is employed as a final check on the compatibility test and is prescribed for almost universal use. The various clinical reactions associated with transfusion are differentiated. The serologic features of transfusion are presented with recommendations to insure the obtaining of adequate grouping and compatibility tests. Various transfusion techniques are described and illustrated. The indications for transfusion are, admittedly, given rather broad consideration, the question of the donor, however, is given practical consideration. The subject of hemolysis recurs throughout the book. In defining his concept of this, the author refutes the statements of his critics and gives clinical descriptions of the phenomenon, its results and treatment.

The Organism of the Mind. An Introduction to Analytical Psychotherapy. By Gustav Richard Hever, M.D. Translated by Eden and Cedar Paul. Cloth. Price \$3.50. Pp 271 with 37 illustrations. New York: Harcourt, Brace & Company 1934.

This is a series of lectures, covering generally the subject of psychotherapy. The class of persons for whom it was designed is not obvious, but the subject matter is treated in a way that would imply that the audiences for these lectures were composed of nurses or educated laymen rather than physicians. The general tone of the book is philosophical, and the specific treatment of disease entities is not discussed. While the author's point of view is a modification of Jung's analytic psychology, mechanisms are drawn from Freud and Adler to develop a somewhat unique system of psychotherapy. Infantism, particularly the inability of the individual to cut the strings binding him to his mother, and sexual maladjustments are particularly stressed. The book is composed of two sections. The first part treats of organic expressions of the conflict brought up in the patient when he is attempting to meet some difficult problem of adjustment. An example of this is the vomiting that occurs in an individual who cannot meet some problem, which would imply the existence of an organic disorder, although no detectable organic disorder exists in the patient. This is shown not only in the sphere of the digestion but also in the spheres of the circulation and respiration. When he discusses the latter, Dr. Hever becomes theoretical and religious. The second part of the book is a rather disconnected discussion of the schools of psychotherapy that are outgrowths of the Freudian doctrines which the author, for that reason, calls schools of psychoanalysis, even though Adler claims that individual psychology is not a school of psychoanalysis. In the hands of Hever, modified techniques from each of the modern schools of psychotherapy have been of value, but what he admits as coming from Freud and Adler he does not find so useful as what he gets from Jung. His discussion is so philosophical and general that its value to the practicing psychiatrist is somewhat doubtful but it does reveal a point of view that is likely to be more

impressive as psychiatry develops, namely, the eclectic attitude, which will encourage the taking of the best from each school of psychiatry. Heyer points out that what we in America call egomorphism, i. e., leaning of the therapist toward schools of therapy which stress his own needs, is an important feature. It is this tendency of psychiatrists which will be likely to bring on the author the most severe criticisms, for any one trained in a specific school of psychotherapy—particularly the Freudian school—will be apt to raise the cry of superficiality and inadequacy. There are a number of rather senseless diagrams scattered throughout the book, and there is a large section at the end showing the drawings of various cases from which the author interprets various mental mechanisms.

Compensation of Physicians Liability of Husband When Credit Extended to Wife—The plaintiff rendered medical services to the wife of the defendant. The plaintiff testified that he entered on his account book a charge against the wife. Two payments were made on the account both by the wife. When the wife made no further payments, the physician sued her husband and secured judgment in the trial court. The husband appealed to the Supreme Court of Ohio.

Medical services are necessities, said the Supreme Court. While in years gone by the courts of Ohio and other States were inclined to hold that the marriage relation created an unconditional liability on the part of the husband for necessities furnished the wife, the law in its wisdom, as women gradually entered man's former sphere, relaxed its requirement so far as the husband was concerned. It shifted some of the responsibility from his shoulders to the shoulders of the wife. In Ohio this gradual process of alleviation has changed the husband's duty to furnish his wife necessities, from an unconditional to a conditional duty. Consequently the liability arising from a breach of this duty is conditional.

The testimony in this case shows said the Supreme Court that if the physician knew that his patient was married he at no time regarded that fact as giving his account added security. He rendered the services to the wife, at her request, he made all charges against her on his account book, and, as he testified he looked to her for his pay. It is only fair to assume that it was not until the physician learned that his account against the wife was not collectible that he proceeded against the husband. Furthermore, said the court, the account book which was admitted in evidence, was not admissible against the husband. If the physician testified that it was his account book, that it was a book of original entries, that the entries were made by him or by some other person under his supervision duly authorized, the account book would then be admissible in evidence, to speak for itself, it could not speak against the husband, for his name nowhere appeared in it. The Supreme Court concluded, therefore, that there was no liability on the part of the husband to pay for the medical services rendered the wife, under the facts in this case and reversed the judgment of the trial court in favor of the physician—*Tille v Finley (Ohio)*, 186 N E 448.

Arteriosclerosis Aggravation by Exposure to Thermic Changes—The employee in this case, in the course of his employment, frequented rooms in which the temperatures ranged from zero F to 22 degrees below zero, F. Often he noticed on leaving these rooms, a numbness in his right foot, which disappeared when he stamped his feet. On Dec 4, 1930, however, the numbness persisted and extended throughout the foot with gradually increasing symptoms. He continued his usual duties until Jan 3, 1931, when he was compelled to quit because of the condition of his right leg. The femoral artery and vein of the right leg were resected, January 5 and the resected portions showed arteriosclerosis Monckeberg's type. The operation did not afford relief, and it became necessary to amputate the leg above the knee. The employee sought compensation under the Longshoremen's and Harbor Workers' Compensation Act, made applicable by statute to employees

generally in the District of Columbia. An award was made by the deputy commissioner, the supreme court of the District of Columbia enjoined its enforcement, and the employee appealed to the Court of Appeals of the District.

The evidence definitely showed, said the Court of Appeals, that exposure to thermic changes, such as occurred in this case, would aggravate a preexisting condition of arteriosclerosis and cause a condition such as that suffered by the claimant. The fact that he was diseased does not bar his right to recovery for accidental injury, notwithstanding the fact that except for his diseased condition the injury would not have occurred. On account of the disease condition of the blood vessels, the frequent, daily exposure to the intense cold set into motion a chain of circumstances that resulted in the amputation of the leg. This constituted an accidental injury within the contemplation of the act under which this proceeding was instituted. The deputy commissioner erred, however, in holding the insurance carrier liable for the physician's and hospital's bills, contracted by the employee. The Longshoremen's and Harbor Workers' Compensation Act requires a physician, when he looks to an insurance carrier for his fee, to report his services within twenty days. This was not done in this case, and there is no provision in the act which permits the deputy commissioner to waive the requirement. Under such circumstances, said the court, the insurance carrier was not liable. The decree of the supreme court of the District of Columbia, enjoining the enforcement of the award, was reversed—*Hoage v Employers Liability Insurance Corporation, Ltd (D C)*, 64 F (2d) 71.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Micromethod for Estimation of Proteins in Plasma—Medes describes a micromethod for the estimation of the protein fractions of plasma in which 0.7 cc of plasma is required for complete fractionation. For fractionation into fibrinogen, albumin and globulin, 0.4 cc of plasma is used. The method depends on fractional salting out with anhydrous disodic sulphate, precipitating the protein remaining in the various filtrates with trichloroacetic acid, dissolving the precipitates in sodium hydroxide and determining the nitrogen in an aliquot part. The error of the determination is not greater than that of the corresponding macromethod. The author checked this method against the corresponding macromethod in which 1 cc of plasma is used for each fraction and found it to check within the limits of error of the macromethod.

Sacrococcygeal Chordomas in Children—During a period of eighteen months, Montgomery and Wolman observed sacrococcygeal chordomas in three children of 3 and 3½ years and 22 months, respectively. They believe that the presence of a pelvic tumor in children associated with signs of obstruction of the bladder or intestine is suggestive of a chordoma. The diagnosis can be made by the finding of characteristic physaliphorous cells in the fluid obtained by exploratory puncture. The ideal treatment is complete surgical extirpation of the tumor with the surrounding tissues. This is almost always impossible, as the growth involves contiguous vital organs such as the nerves the intestine and the bladder. Even when a complete surgical removal has been done as in the patient of Mazzia and Vecchi, the tumor has recurred. However, there

is no question that the lives of some patients have been prolonged many years by the repeated removal of large portions of the tumor as it grew back. According to many authors, irradiation usually causes no subsidence of the tumor, although it may relieve pain. Two of the authors' patients seemed much improved after a course of high voltage roentgen treatments.

Schultz-Charlton and Calcium Tests in Scarlet Fever—Fischer and Kojis observed the results of the Schultz-Charlton test in 486 cases and the calcium tests in seventy-five cases. They found that the Schultz-Charlton test is specific for the rash of scarlet fever. A 10 per cent solution of calcium gluconate will cause slight blanching in some recent cases of scarlet fever in which a mild or moderately intense rash is present. This action, however, is not so constant or so persistent as that obtained with dilute scarlet fever antitoxin. The actions of calcium and of antitoxin on the rash of scarlet fever are totally different. The fact that calcium will blanch a rash does not in any way detract from the validity of the Schultz-Charlton test. Provided its limitations are understood, the latter is invaluable in the early diagnosis of scarlet fever.

The Cat in the Transmission of Diphtheria—Brooks performed the Schick test on seventy cats and kittens with one twenty-fifth minimal lethal dose per cat. None of the animals showed a positive reaction. Injections of a standardized toxin, however, were found to be capable of causing death in these animals, the minimal lethal dose of diphtheria toxin for kittens being five times as great as the standard minimal lethal dose for guinea-pigs. Five cats were killed with diphtheria toxin. Four of five cats into which injections of toxin were made were protected by appropriate doses of antitoxin. It therefore appears that cats react both to diphtheria toxin and to antitoxin in the same way as do guinea-pigs. Diphtheria bacilli survived as long as twenty-four hours on the normal and scarified pharyngeal mucosae of cats and kittens. In symbiosis with the fusiform bacilli and spirochetes of Vincent's angina, diphtheria bacilli lived on the scarified pharynx for four days. The diphtheria organisms were found not to live in the nose and lungs of the kitten and the cat for longer than five days. The author has been unable to confirm the work of earlier investigators by producing in cats any condition suggesting diphtheria and to obtain growth of diphtheria organisms on the trachea of a cat, with formation of a membrane and death. He recovered the organisms from the fur of cats for three days, whereas Remlinger recovered organisms for twenty-four days. The author agrees with Savage that cats, while susceptible to parenteral injections of diphtheria toxin, are not susceptible to diphtheria. He does believe that cats may act as carriers from one to four days after exposure to diphtheria, through contamination of the rhinopharynx or fur, and that cats suffering from an infection of the pharynx with Vincent's fusiform bacilli and spirochetes are more likely to harbor and carry the diphtheria bacilli on the pharynx than are healthy cats.

Spirochetes in Brains of Dementia Paralytica Patients

—Using the Jahnke method, Kopeloff and Blackman found spirochetes in the brains of six of thirty-nine dementia paralytica patients treated with malaria. Degenerate forms of spirochetes were encountered in more instances than normal forms. Three of these patients came to necropsy shortly after malarial inoculation (within six weeks). Spirochetes were found by the Jahnke and Dieterle methods in eight of ten dementia paralytica patients not treated with malaria and none were found in a normal brain. The authors, having thus established the validity of the technical procedure, state that within the limitations of the material at hand it appears that (1) artificially induced malaria is likely to destroy spirochetes in the brain of dementia paralytica patients or (2) that, failing to destroy the spirochetes completely, this form of therapy alters the morphology of Spirocheta pallida to such a degree as to render it degenerate in appearance.

Arsphenamine Encephalitis—Globus and Ginsburg describe two cases of death caused by arsphenamine, one of which occurred in a nonsyphilitic patient. In one case the lesions were mainly perivascular hemorrhages due to rupture of the smaller capillaries, moderate reactive gliosis in response to the toxic substance which had oozed through the injured vessel wall and diapedesis. The other case was one of the acute form of disseminated sclerosis involving the cerebrospinal axis in the typical disseminated fashion. The sclerotic areas presented only degenerative alterations such as demyelination, destruction of axon cylinders and massive accumulation of compound granular cells. The absence of inflammatory lesions excluded even the remote possibility of a syphilitic process. The hemorrhagic lesions were identical with those in the first case and bore no relationship to the underlying disease, which was typical of so-called acute multiple sclerosis. The hemorrhagic lesions were unquestionably provoked by the sulpharsphenamine. In view of the changes in the brain the authors suggest that there is no justification for the use of such terms as 'arsphenamine encephalitis' or 'hemorrhagic encephalitis' and that the term 'pericapillary encephalorrhagia due to arsphenamine' is more appropriate.

Dystrophia Myotonica—Keschner and Davison report two cases of dystrophia myotonica in siblings. One was subjected to a complete histopathologic study, and in the other a biopsy of one of the affected muscles was performed. The principal pathologic observations were changes in (1) the muscles, (2) the endocrine glands (pituitary, suprarenals and testicles) and (3) the nervous system. The lesions in the nervous system consisted of (1) alterations in the ganglion cells of the lateral cell columns (sympathetic) and (2) changes in the nerve cells of the paraventricular and supra-optic nuclei. The neural lesions may possibly be regarded as retrograde degenerations. From a critical review of the necropsy observations in the cases recorded in the literature and in one of their cases it appears to the authors that the disease is one of a primary involvement of the muscles, a true muscular dystrophy (a myopathy). The histologic observations in the cases reported as well as in their case give no clue as to the cause of the myotonia, a clinical manifestation that distinguishes the disease from the other clinical varieties of muscular dystrophy.

Puncture of the Cisterna Magna—The modification by Gilman and Kempf of Ayer's method for puncture of the cisterna magna is as follows. A needle of larger gage (16), which is not very flexible and has a small hilt, with the bevel directed caudally so as to avoid skin tissues from the occiput into its lumen, is inserted into the skin in the exact midline just at the upper border of the first spinous process. If the needle is started in the exact midline at this point and directed at a point in the exact midline at the usual place for the hair line, one can in many cases slowly and steadily carry the needle into the cisterna magna without changing its course. When the needle has been passed through the skin and outer ligaments, the stylet is removed. One then gradually pushes the needle toward the cisterna, never allowing the tip to point below the eyebrows and attempting to keep it pointed as nearly as possible toward the hair line. In order to insure a steady and gradual movement of the needle and to avert its going too far when it passes through the dura, it is best to hold the needle with both index fingers and thumbs, keeping the remaining fingers against the patient's neck and head for support. As soon as the tip of the needle passes through the dura, spinal fluid appears, and with the larger needles even purulent fluid appears at once. When fluid does not appear after the proper distance has been traversed by the needle, and when it cannot

be secured with a syringe, the tap should be called a dry one and the puncture should be stopped. The authors conclude that the important points of their modified technic are (1) to locate the depression below the occiput, the mastoid process and the normal hair line, (2) to start and to keep the needle in the exact midline, (3) to keep the bevel directed caudally and to remove the stylet as soon as the needle has passed through the outer tissues, (4) to hold the needle with both thumbs and forefingers and to steady both hands against the neck and head of the patient and (5) to start the needle low (just above the epistropheus).

*Major Surgical Operation on Case of Myasthenia Gravis G B Fletcher and J S Stell Hot Springs National Park—p 129

Operation on Patient with Myasthenia Gravis—Fletcher and Stell report a case of myasthenia gravis in which a major surgical operation has been performed. The patient, shortly after the birth of her third child, noticed some weakness of the right hand and arm. Later there developed mask-like facies, typical muscular weakness (especially toward the end of the day), mild ophthalmoplegia, difficult deglutition, huskiness of the voice and what she refers to as occasional asthmatic symptoms, which, as a matter of fact, were probably due to involvement of the respiratory muscles. She was placed on ephedrine sulphate from 3 to 8 grains (0.2 to 0.5 Gm) twice a day and showed marked improvement. Three years after the birth of the child the patient stated that she was much better than when she began the use of ephedrine sulphate but still had difficulty toward the end of the day, especially in swallowing, in talking and in the use of the larger groups of muscles. There was a tendency for mucus to accumulate in the throat and she was unable to close the eyelids entirely, there was a mask-like expression, an inability to whistle and to smile and a tendency for the corners of the mouth to turn upward. There was weakness of the right arm and hand power being 30 Kg right and 65 Kg left, the weakness being especially on the ulnar side of the hand, giving somewhat the appearance of the so-called benediction hand. The right mid-arm was about one half inch smaller than the left. Pelvic examination showed the uterus to be in a state of rather marked retroflexion and the cervix showed a deep "alligator mouth like" tear. The vaginal canal showed a tear and the patient complained of marked vaginal discharge. A hysterectomy was performed under spinal anesthesia through an abdominal incision. The intention was to repair the vaginal tear also, but it was thought advisable not to subject her to more than the hysterectomy at this time. She went through the operation well and the ephedrine was increased temporarily to three times a day. Twelve days after the hysterectomy the patient was given 15 Gm of glycine two times a day. Convalescence was uneventful. She no longer complains of the so called asthmatic attacks and feels that these began to disappear shortly after she began the ingestion of glycine. The tendency for mucus to accumulate in the throat is not so much in evidence. The vaginal discharge has almost disappeared.

Late Congenital Syphilis—Smith presents a study of constitutional factors in 462 patients with late congenital syphilis and the results of treatment in 267 of these patients who were observed for more than two years. The data indicate that the clinical arrest of late congenital syphilis, with or without obvious lesions, unless the nervous system is involved may be accomplished with as little as six months of antisyphilitic treatment with an arsphenamine and a heavy metal, that the clinical results are the same regardless of whether the Wassermann reaction becomes negative or not, and that the optimal amount of treatment depends largely on the disappearance of clinical signs and symptoms, varying between six months and three years. The response of the blood Wassermann reaction may be completely disregarded as a guide to the type of treatment or to its duration.

Micro-Organisms in Frozen Pack Foods—Berry presents data showing a decrease of approximately 40 per cent in micro-organisms on blackberries stored in airtight and non-airtight containers for thirteen months at -20°C , of 99 per cent at -10°C and in airtight containers only, of over 99 per cent at -2°C . Also with strawberries a decrease of 60 per cent in micro-organisms has been shown in both airtight and non-airtight containers stored four months at -20°C , of 89 per cent at -10°C and -7°C , and in airtight containers only, of 94 per cent at -4°C . With raspberries stored fourteen weeks the decrease was 61 per cent at -20°C , from 95 to 97 per cent at -10°C and -7°C and 99 per cent in airtight containers only, at -4°C . Possibly the greater respiratory activity of raspberries is reflected in these percentages. No significant microbiologic differences have been noted between sealed containers and partly vacuumized containers stored at the same temperature. Studies on the fate of micro-organisms in artificial mediums at various freezing temperatures have been recorded and indicate that the death rates in such are not comparable to those when the medium is fresh fruit. It has been suggested that carbon dioxide from respiration of the fruit is responsible for the high death rates at -10°C and -27°C and when the container is airtight, at -4°C and -2°C . The author presents the growth of *Cladosporium* species at -2°C ,

and of *Oidium* and torula species at -4°C on small fruit in non-airtight containers and the evidence that lactobacilli and to a lesser extent "colon" organisms persist in peas for at least two years at -10°C and "colon" organisms in string beans and spinach at -10°C for at least nineteen months and ten months, respectively. It has been further noted that bacteria, presumably of the *Pseudomonas* genus, will increase in peas stored at -4°C . The author compared the effect on *Saccharomyces* species of a temperature of -10°C , when the medium remains liquid with the effect at -10°C when the same medium freezes and presents figures showing the destructive effect of the formation of ice on the test organisms.

Variation in Hemolytic Streptococci—Spicer discusses the morphologic, cultural, biochemical and immunologic phases in the dissociative processes, both spontaneous and induced, of seven strains of hemolytic streptococci from scarlet fever and erysipelas cases. These strains are stock strains of known types that have been worked with before and of known physiologic and serologic characteristics (Williams and Gurley, 1927). They are type strains, representative of four scarlet fever groups and three erysipelas groups into which most of the strains fall by the agglutination absorption reaction. Of the seven strains under study, four yielded spontaneous dissociation (two of scarlet fever and two of erysipelas) while, from the remaining three strains variants were obtained by induced dissociation (two of scarlet fever and one of erysipelas).

- *Further Observations on Cultivation of Vaccine Virus for Jennerian Prophylaxis in Man. T. M. Rivers and S. M. Ward. New York.—p. 635

Isolated Human Strains and Poliomyelitis Virus—Paul and Trask confirm the qualitative differences that exist between so-called human and passage strains of poliomyelitis virus by the following observations: 1. The experimental disease induced by two human strains usually failed to protect monkeys against a subsequent infection by a passage strain, and in the few instances in which the reverse experiment could be tried a similar lack of protection was observed. 2. In some human serums the neutralizing power for a human strain differed qualitatively from the neutralizing power for a passage strain. The time interval between the intracerebral inoculation of heterologous strains has been found to be an important factor bearing on the results of the reinoculation experiments reported. Within the intervals used the greater the period between the original infection and the reinoculation with a heterologous strain, the less was the degree of cross immunity observed.

Cultivation of Vaccine Virus for Jennerian Prophylaxis—Rivers and Ward passed a dermal strain of vaccine virus through ninety-nine successive culture passages. This procedure led to a diminution in the pathogenicity of the active agent for the rabbit. By repeated testicular passages in rabbits the virus regained its pathogenicity for that host. New cultures were initiated with the revived virus. A culture strain of virus that has been twice revived in this manner has remained fairly stable for the rabbit through sixty cultural passages and it produces mild, yet effective, vaccinal reactions in man. Virus in early cultures was not attenuated for man, but later cultures of the original strain and cultures of the second and

third revived strains produced mild reactions without fever and discomfort to the patients. Intradermal vaccinations with the culture virus are safe and satisfactory. With the culture virus 118 infants and children have been inoculated, and in 100 of them a positive reaction occurred. The culture virus produced a refractory state to a standard dermal strain of calf lymph and vice versa. Culture virus stored in 50 per cent neutral glycerin at -10°C or at $+3^{\circ}\text{C}$ maintained a considerable amount of its activity for at least one year. Desiccated culture virus sealed in tubes maintained some of its activity when stored at 37°C for five weeks. Fresh cultures can be initiated without difficulty from desiccated virus or from virus that has been stored with or without glycerin.

Radium Dial Painting—Schwartz and his associates examined 242 persons exposed to radium and thirty-one girls who were not exposed to it. There was evidence of the accumulation of radioactive material in the bodies of radium dial painters and other radium workers, not only in those who were exposed to radium for more than two and a half years but also in those who were exposed less than this time. No indication of the presence of radium was noted in the controls. Roentgenograms of the alveolar regions of workers exposed to radium for two and a half years or less did not indicate any bone changes that could not be attributed to dental causes. On the other hand, red cell and hemoglobin determinations showed, on the average, a slight tendency to be lower in this group than among the controls. It is therefore felt that the abolition of pointing the brush with the mouth and other changes in practice which may have been introduced at the same time have not entirely solved the problem of radium deposition in the bodies of radium workers in the dial painting industry. Determinations of radioactivity of the dust in the air of the workrooms and of the radon in the air suggest that the inhalation of radioactive material is a factor as well as the ingestion. In making suggestions for preventing radium poisoning the authors have had in mind extreme cleanliness in the factory, thorough personal cleanliness of the workers and adequate ventilation, both general and local.

Journal of Nervous and Mental Disease, New York

78 453 580 (Nov.) 1933

- Mental Aspects of Brain Tumors in Psychotic Patients. Study of Twenty Six Verified Cases. G. R. Jameison and G. W. Henry. White Plains, N. Y.—p. 500

Encephalography in Abnormal Mental States—Schube reports the cases of three persons presenting neuropsychiatric problems in whom diabetes insipidus was observed after the patient had been admitted to the hospital. One was diagnosed as schizophrenia with diabetes insipidus, one as epileptiform seizures probably organic with diabetes insipidus, and the other as mental retardation probably organic, with diabetes insipidus. Two of the patients were relieved of their diabetes insipidus.

immediately following encephalography. Alleviation of the symptoms of diabetes insipidus has not heretofore been reported as the result of the encephalographic procedure, but there have been reports of the relief of this symptom complex by means of lumbar spinal puncture with the removal of a few cubic centimeters of spinal fluid. Herrick, Graham, Cammidge, Tucker and King each reported a case in which diabetes insipidus was cured by lumbar puncture. The procedure in one of the author's cases alleviated the symptoms of the diabetes insipidus but accentuated the abnormal mental state, in the second case it alleviated both the diabetes insipidus and the abnormal mental state, and in the third case the diabetes insipidus and the abnormal mental state remained unchanged.

Tumors Involving the Gasserian Ganglion—Cohen removed successfully a tumor of the gasserian ganglion in a woman of 32 whose chief complaint was headache and loss of vision, and who under an observation of six weeks began to complain of severe pain in the face and with the pain developed a hypesthesia going on to anesthesia of the fifth nerve. At operation the author removed a meningioma springing widely from the dura of the middle fossa extending from the clinoids laterally. The patient recovered normal sensation and has had no symptoms referable to her fifth nerve in the three years since the operation. In spite of the fact that in the history of the patient's illness pain is conspicuous, it never seemed a prominent feature during her preoperative observation. Sedatives were rarely required. A widening of the sphenoidal fissure as was shown roentgenologically has not, to the author's knowledge, been noted before in such a tumor. It was one of the factors in leading to a wrong preoperative diagnosis. A unilateral exophthalmos was another feature that seemed to point to a meningioma probably arising from the sphenoidal ridge. While an extradural approach would have been made had the nature of the lesion been suspected, the intradural method did not add to the difficulties of the operation. It made, in fact, the exposure of the mesial limits of the tumor easier.

Abdominal Symptoms in Diabetic Acidosis—McKittrick studied cases reported in the literature, reviewed the records of the diabetic coma cases at the Massachusetts General Hospital and observed the large series of cases placed at his disposal through the courtesy of Joslin. The histories of emergency operations in diabetic patients under his own personal observation have been studied in detail. The observations in postmortem examinations of patients who have died in coma have also been utilized. On the basis of these observations the author concludes that one is justified in saying that a history of malaise, drowsiness, vomiting and diffuse abdominal pain associated with widespread tenderness and spasm is so suggestive of diabetic acidosis without demonstrable intra-abdominal pathologic changes that operation should not be done unless the abdominal symptoms persist after three or four hours of adequate insulin treatment. Conversely, a history of

abdominal pain with or without vomiting, when associated with localized and definite abdominal tenderness, usually with spasm, is suggestive of a surgical lesion within the abdomen in the patient with diabetic acidosis, just as it is in the nondiabetic patient, and may be an indication for immediate operation. In that rare case, in which definite differentiation is impossible and yet imperative, it may be safer to open the abdomen under local anesthesia than to suffer further delay.

Benzyl-Methyl-Carbinamine-Carbonate in Treatment of Rhinitis—Byrne treated fifty-one cases of rhinitis with benzyl-methyl-carbinamine-carbonate. The results obtained in the treatment of vasomotor rhinitis (hay fever) and acute rhinitis were encouraging. There was definite proof, in this type of case, that the amount of secretion was diminished, the subjective itching and feeling of fullness relieved and decongestion of the mucous membrane accomplished. The results obtained by using the drug in patients having sinusitis were poor and, in certain instances, increased rather than diminished the severity of the symptoms. The drug should be used after a careful examination of the nose has been made by a competent rhinologist and the character and cause of the rhinitis determined. The drug should be prescribed with careful directions. The ease of administration (inhalation) of the drug recommends itself to the ambulatory patient and tends to make more certain the patient's use of the material.

Treatment of Amebic Dysentery—Strong states that the treatment of amebic dysentery should receive careful supervision. During the acute stages, the patient should be kept in bed. If bowel movements are numerous, only liquid diet should be allowed. In general the diet should be regulated according to the frequency and character of the stools and should be bland in all cases. Emetine, he says, is the standard drug for specific treatment. It should be given during the acute stages of the disease in doses (for adults) of 1 grain (0.065 Gm.) of emetine hydrochloride dissolved in 1 cc. of distilled water, either by hypodermic or by intramuscular injection, this dose being continued for a week to ten days, or even twelve days if special susceptibility to the drug is not manifested. Such treatment in a number of cases does not cause complete eradication of the infection, and if amebas are still present in the feces it should be supplemented by a second course of treatment with the double iodide of emetine and bismuth (emetine bismuth iodide), containing about 26 per cent of emetine. Doses of 3 grains (0.2 Gm.) of this preparation should be given by mouth for ten or twelve consecutive days. In cases of peripheral neuritis occurring after treatment with emetine, the symptoms are usually general muscular pains and weakness, especially in the legs, progressing sometimes to paresis. Wrist drop and toe drop may occur. These symptoms, however, usually disappear gradually with the stopping of emetine. In six of twenty cases of poisoning from the use of emetine collected from the literature, less than 10 grains (0.65 Gm.) was given. All recovered except one patient who received daily subcutaneous injections of 1½ grains (0.1 Gm.) of emetine hydrochloride for twenty days, a total of 29 grains (1.9 Gm.). Diarrhea also may be an important symptom of emetine poisoning. Many cases of amebic dysentery, particularly those presenting advanced lesions, do not yield to treatment with emetine, therefore amebic dysentery should be treated early and symptoms of relapse should have prompt and careful attention.

Sodium Dehydrocholate in Cholecystography—Jankelson and Altman present an analysis of ninety-eight consecutive cases of cholecystography with the aid of sodium dehydrocholate. The technic used is as follows: The evening preceding the roentgen examination, the patient is given a light meal and two hours later the dye (tetraiodophenolphthalein) is given by mouth. If the patient is particularly distressed, sodium bicarbonate may be taken. Ordinarily neither food nor liquids are given to the patient for the next fourteen hours until the roentgen plates are taken, then 10 cc of a 20 per cent solution of sodium dehydrocholate is administered intravenously whether or not the roentgenograms taken fourteen hours after the oral administration of the dye reveal the gallbladder shadow. Further roentgenograms are taken forty-five minutes later. If the gallbladder shadow is demonstrated on the roentgenograms after the intravenous injection of sodium dehydrocholate, the patient is given a fat-protein meal and other roentgenograms are taken two hours later. The radiographic technic used was worked out painstakingly, so that all roentgenograms in the individual case were taken with the same kilovolt peak, the same plate-target distance and the same length of exposure. In the absence of serious pathologic changes of the liver failure to demonstrate an increase in the size of the outline of the gallbladder within forty-five minutes after the administration of sodium dehydrocholate is evidence that the gallbladder has lost its normal capacity to enlarge with the ingress of bile. Some diverticula and adhesions about the gallbladder are better demonstrated after the administration of sodium dehydrocholate. Sodium dehydrocholate seems to be of little value in indicating stones within the gallbladder.

Calcium (Psammoma) Bodies in Fallopian Tubes—According to Wilson calcium (psammoma) bodies are not infrequently present in chronic inflammatory and neoplastic diseases of the fallopian tubes and ovaries. The bodies occasionally form serosal tubercles, which are macroscopically indistinguishable from those commonly observed in tuberculous salpingitis. They also form microscopic lesions which are erroneously thought by some clinicians and pathologists to be tuberculous or posttuberculous in character. This error may explain the high incidence of tuberculous salpingitis reported by some hospitals and clinics. The genesis of psammoma bodies in the adnexa is unknown. The chemical composition of the bodies suggests that they may be explained on the basis of an altered tissue metabolism, which results in a precipitation of the lime salts normally present in all tissue juices. The author reports a case that presents a rare histologic picture (sections of a fallopian tube) which is generally unfamiliar to clinicians and pathologists and does not appear in the current literature dealing with pathologic conditions of the adnexa. Every section of the tube contained numerous concentrically laminated foreign bodies many of which resembled the sectional remains of intestinal parasites.

Chorionic Carcinoma—Salisbury reports a case of chorionic carcinoma, following a hydatidiform mole, in which there had not been recurrence five years after operation. He was of the opinion that the bleeding came from a chorionic carcinoma and not from the retained products, so that he decided not to risk further hemorrhage or dissemination by exploring the cavity but to perform a hysterectomy as soon as the patient's condition permitted. Under a general anesthetic the vagina was swabbed out with violet green the cervix closed with a mattress suture and the abdomen opened by a subumbilical incision. The uterus was about the size of an eight weeks pregnancy, there was no sign of growth on its peritoneal surface or invading the broad ligaments or glands, nor were there any metastases in the abdomen. An ordinary panhysterectomy was performed including the fallopian tubes. Recovery was uneventful and the patient was discharged to a convalescent home on the fifteenth day. The uterus contained a soft, dark red ovoid growth measuring 3 by 1.8 by 1.4 cm, and arising in the posterior wall of the body, its lowest point was 1 cm above the internal os. It protruded into the uterine cavity and was in part covered with mucous membrane at its center it invaded the uterine wall for half its thickness. No vesicles of the preceding mole were present. Microscopic examination showed the structure of a chorionic carcinoma. The muscular wall was infiltrated with large cells from Langhans' layer. There were some small syncytial masses and there appeared to be one formed chorionic villus. There was a large amount of blood among the cell masses. The patient is perfectly well and free from all signs of recurrence five years after the operation and has gained slightly in weight.

Treatment of Fractured Nasal Bones—Watkins describes a method for the treatment of fractured nasal bones based on a splint described by Carter. The author first modified the splint by substituting U-shaped metal splints for Carter's straight intranasal splints one limb of the splint being inserted so that when traction is taken from the part of the limb outside the nose opposite the middle of the nasal bone the effect is the same as if short intranasal splints were used and traction were taken from the middle of them. In order that the splint should not work in farther or work out when tension was applied it was found essential that such tension should be applied exactly at right angles to the axis of the nasal bone. This is obtained by adding a mast the effective length of which can be varied from the forehead to the apex of the splint. Grooves are cut on the mast and a silk thread from each U splint is tied to its fellow on the opposite side over the correct groove in the mast in such a way that the direction of the pull is at right angles to the nasal bones. The bases of the splint are fitted with thick rubber tubing and are used only for counterpressure on the face. When wounds are present

they are avoided by adjusting the distance between these rubbers with a milled screw. If, during treatment, the silk threads need only slight tightening, this is effected by adjusting the screw to narrow the angle between the two sides of the splint. The forehead piece of the splint is padded with a flat piece of rubber and kept in place with a band of adhesive strapping round the head. Nasal respiration is possible during treatment. The splint is left in about four days, though at any time it may be removed (all except the mast) for the dressing of wounds and the use of douches, and it can readily be reapplied. Adjustments may be slackened after this period and recurrence of deformity watched for. If none occurs the splint is removed, otherwise it is replaced. Treatment varies from a few days up to about three weeks.

Physiologic Activation of Insulin—Himsworth investigated the effect of high carbohydrate and high fat diets on hyperglycemia after the ingestion of 50 Gm of dextrose and on the rate of depression of the blood sugar after a standard dose of crystalline insulin. Simultaneous curves in capillary and venous blood have been obtained after the oral administration of dextrose. After an intravenous injection of crystalline insulin, a short latent period occurred in which there was no detectable action of insulin on the blood sugar. This was succeeded by a period in which insulin manifested its action with increasing velocity. After a period on a high carbohydrate diet the oral administration of dextrose was followed by a lower and less prolonged hyperglycemia and an earlier development of the venous step, and the injection of a standard dose of insulin was followed by a shorter latent period and a more rapid rate of fall of the blood sugar than when the subject was taking a high fat diet. The same results were obtained when doses of dextrose were given to a subject prior to investigation. The author concludes that the administration of carbohydrate stimulates the production of the unknown "insulin-kinase" and discusses the association of disease or injury of the liver with the development of insulin activity.

Observations on Angina of Effort—Wayne and Laplace observed for more than a year eleven patients in whom effort alone induced attacks of anginal pain. The amount of such exercise in successive control tests, was found to be constant in any one case. The appearance and disappearance of pain was unrelated to the height of the blood pressure, but in most cases a relation to the heart rate could be shown. In four patients who received atropine it caused a diminution in the amount of exercise required to produce pain and the attack was prolonged. Pressure on the carotid sinus diminished the duration of pain. The inhalation of amyl nitrite reduced the duration of pain but its disappearance showed no relation to the fall in blood pressure. After glyceryl trinitrate, which in all but two cases increased the exercise tolerated, pain often arose at blood pressures no higher than normal. Erythrol tetranitrate increased the amount of exercise tolerated in only three subjects, although the pulse and blood pressure were usually considerably affected. In one, both amyl nitrite and glyceryl trinitrate prolonged the pain. In two of four patients, all of whom had responded well to glyceryl trinitrate, intravenous theophylline ethylenediamine gave only a slight increase in the amount of exercise that could be taken before pain arose. Prolonged rest in bed had a more favorable influence on the amount of exercise tolerated in cases of recent onset than in those of longer standing. The authors' results are consistent with the view that anginal pain is due to a relative myocardial ischemia. The rise in heart rate which is more important than the raised blood pressure, increases the energy

expenditure of the heart without a concomitant increase in the coronary flow. The beneficial action of the nitrites in angina of effort is due to dilatation of the coronary vessels and not to the fall in blood pressure which they produce.

Occurrence of Diphtheria in Immunized Persons—
Saunders discusses the seventy-eight cases of diphtheria that occurred among a group of 8027 immunized children (6,878 fully and 1,149 partially immunized). In thirty-three instances the diagnosis was not confirmed in the hospital (42.3 per cent). In eighteen instances treatment was incomplete or the "latent period" had not expired. In twenty-seven cases the necessary conditions for the development of immunity had been fulfilled. In nine of these the diagnosis was extremely doubtful, and in four others it was doubtful. Of the remaining fourteen cases, twelve had not been Schick tested after treatment. Diphtheria was reported in seven known Schick-negative reactors (two primary and five secondary) but in five of the cases the diagnosis was extremely doubtful. Two negative reactors (both secondary) developed definite diphtheria. With two exceptions, the response to antitoxin treatment in the "immunized" cases was rapid and complications occurred in only one instance (in the form of cardiac irregularity). In all cases recovery was eventually complete.

Partial Thoracic Stomach with Short Esophagus—
Monkhouse and Montgomery report seven cases of partial thoracic stomach with short esophagus of mild degree. In six, the diagnosis was confirmed by esophagoscopy and in one by roentgen evidence alone. These cases fall into two groups, those with and those without dysphagia. Both types have pain that resembles the flatulent dyspepsia of cholecystitis. The dysphagia is not steadily progressive as in carcinoma but is intermittent and for some time often years is not severe. It is due to the presence of an ulcerated stricture. Hematemesis may occur in both groups. The diagnosis rests on roentgen and endoscopic examination. In the former, unless the barium is given orally, the lesion is not seen, and it is essential that the passage of the opaque material should be watched on the screen in order to differentiate from a para-esophageal hernia. In cases with dysphagia esophagoscopy shows a stricture possibly with visible ulceration, and mucous membrane removed from this level is found to be gastric in character. In the second group no stricture is seen, but a dilatation may be observed at a level which is certainly above the diaphragm and from which gastric mucosa is obtained. Dilatation will relieve the symptoms in the obstructive type; those without dysphagia receive some benefit from prolonged medical treatment but do not respond well.

3,5-Diiodothyronine in Treatment of Myxedema—
Anderson and his associates observed that 3,5-diiodothyronine, in doses of from 50 to 75 mg daily, is capable of relieving the symptoms of a high grade of myxedema. Under such treatment the basal metabolic rate is restored to and maintained at an approximately normal level, at the same time there is usually a considerable loss of weight and the pulse rate is slightly raised. Toxic symptoms have never been observed. The diagrams obtained are similar to those which would be obtained in response to the daily injection of 1 mg of thyroxine and there seems no reason to doubt that the 3,5-diiodothyronine is acting as a true substitute for the thyroid hormone. The reason for the qualitative similarity between the actions of thyroxine and 3,5-diiodothyronine is not perfectly clear, but an obvious possibility is that a part of the 3,5-diiodothyronine becomes converted into thyroxine itself, a change that requires only the easy introduction of the iodine atoms into the 3' 5' positions. The drug (3,5-diiodothyronine) is a compound that is readily obtainable by a synthetic method in a state of purity, it is, in fact, the penultimate product in the synthetic preparation of thyroxine. Moreover it is perfectly stable. The advantages of such a product for therapeutic purposes over a biologic material such as thyroid are sufficiently evident. It is true that the standardization of thyroid has recently been improved, but the accuracy of this standardization cannot be said to be securely established. Further with biologic material the uncertain factor of deterioration during storage cannot be entirely eliminated. On the other hand, 3,5-diiodothyronine can be standardized with perfect accuracy by its analysis and physical constants, while it exhibits its physiologic activity with a remarkable degree of constancy.

Relation Between Vitamin D and Calculus Formation

—Saiki points out that animals, when fed a fat-soluble-vitamin-deficient diet for a certain duration, undergo calculus formation in their urinary bladders, kidneys and bile ducts. Among them, stone in the bladder is most easily produced and gallstone the most difficult. If the animals are exposed to ultraviolet rays, the formation of calculus is difficult, even when they are fed a fat soluble vitamin-deficient diet with abundant calcium and an insufficient amount of inorganic phosphorus for a long period. The true factor in the production of calculus in animals fed a fat-soluble vitamin is not the deficiency of vitamin A in food but, perhaps, the deficiency of vitamin D.

Calcium Chloride Treatment of Pleural Effusion—

Foix and Grunwald use a 66 per cent aqueous solution of calcium chloride corresponding to 1 Gm of calcium chloride to a soup-spoonful of solution, of which the patient ingests from six to twelve spoonfuls a day. They have seldom observed symptoms of intolerance (vomiting, diarrhea) they attribute this to the low concentration of their solution. Often they have administered calcium intravenously in addition to that taken orally and injected twice weekly 10 cc of a 1:10 solution of calcium gluconate. In twenty-four of forty-eight patients treated, they obtained a rapid defervescence of the temperature, in thirteen the defervescence was obtained in from six to seven hours and in eleven the defervescence lasted for ten days. Among twenty-four patients in whom the results of this therapy were disappointing three had purulent pleurisy and twelve old pleural effusion. Calcic therapy has its best chance for success when it is begun immediately after the appearance of pleural inflammation. In cases of serofibrinous effusion the effect is much slower and often negative and in purulent pleurisy it is always

negative. On the other hand, in some cases the calcic therapy was without effect although it was started at the beginning of the purely inflammatory stage of pleural effusion. According to Blum's theory, natural or artificial inflammation of the pleura may occur only in the presence of sodium. The exudates are essentially composed of water, protein and sodium chloride. On ingestion of calcium chloride the calcium displaces the sodium and, by eliminating the sodium and water, stops the inflammation. Because this therapy appeared efficacious in 70 cases out of 100, generally speaking, the authors think that it is desirable to use this inoffensive calcic therapy systematically to combat the menace of pleural effusions that occur during the course of artificial pneumothorax.

Determination of Coagulation Time of Blood—Santi

employs a capillary tube 5 cm in length and from 0.7 to 0.8 mm in width, the lumen of which is sterilized with alcohol-ether and completely dry. The tip of the finger or the lobe of the ear is pricked with a sterilized needle. Either end of the capillary tube is placed on the drop of blood, the drop is drawn into the lumen of the tube until it fills half or slightly more than half the length of the tube, and the column of blood is made to occupy the middle part of the tube so that it may be removed from any direct contact with air and dust and from the margins of the tube, to which it might easily adhere. The tube is held horizontal for two minutes, after which it is slanted every minute to show whether the column of blood is moving within the lumen of the tube. If so, the capillary tube is again placed in the horizontal position and the process is repeated every minute until the column does not show the slightest displacement. The period between the exit of the blood from the finger and the moment at which the immobility of the column in the tube is observed in vertical position is the time of coagulation. In experimenting with normal persons, the author found that the time of coagulation varies from five to ten minutes at a temperature of 15 C (59 F). At higher temperatures coagulation is accelerated two minutes for each 5 degrees of temperature. At temperatures lower than 15 C the variations are higher and may double the retardation time of coagulation to approximately four minutes. The method revealed gross changes in the coagulation time in three cases of hemophilia, in which the retardation is generally due to diminution in the formation of thrombin. The author studied other diseases in which the blood changes were slighter. In various cases of chronic and acute hepatic diseases there was diminution of the fibrinogen in the blood plasma, in severe anemia and cachexia the deficient coagulability is due not only to reduction of the fibrinogen but also to a deficiency in thrombinase and to a modification of coagulating factors. The author advocates this method for its simplicity.

Duodenal Drainage in Treatment of Uremia—Patiño Mayer and Israel state that duodenal drainage is of great therapeutic value in the treatment of uremia. The method compares in value with bleeding without having the inconveniences of the latter. The removal of 160 cc (more or less) of duodenal content produces a diminution in the urea content of the blood equal to that produced by bleeding of 200 cc. It

is a simple procedure without any secondary ill effects and may frequently be repeated if necessary. The only precaution to be observed in order to obtain good results is to make sure in checking the drainage that the sound is placed in the duodenum and not in the stomach. The author reports satisfactory results in a case.

Rheumatic Pancarditis in Children—Beretervide and Garay study the treatment and prognosis of the grave forms of rheumatic pericarditis in children, which they consider a selective localization of the rheumatic virus in the myocardium, after having been localized in the pericardium and endocardium. The grave forms may be so from the beginning of the disease or may represent the terminal phase of less grave forms. The initial symptoms are similar in both forms but the clinical evolution of the disease is in relation to the degree of myocardial involvement. The treatment is essentially symptomatic during the onset of the pericardial symptoms, and cardiac, tonic and diuretic once the asthyle has been established. Diet is of importance. If there is fever and the rheumatic symptoms persist, treatment with salicylates is also advisable. Because of the poor condition of the myocardium in rheumatic pancarditis the action of digitalis, ouabain and strophanthus is either slight or negative. Caffeine should be resorted to only in serious cases. In general the treatment either fails or causes a temporary improvement in the symptoms without having any action on the tachycardia. In patients of the last mentioned group there is a recurrent asthyle which becomes graver with every new attack. The authors report four cases of rheumatic pancarditis and conclude by saying that up to the present time a treatment capable of preventing the endomyopericardial localization of rheumatic virus is lacking and that the prognosis is fatal in pericardiac forms. Although in less grave forms the immediate prognosis is not fatal, the children cannot reach the puberal age.

Results of Operative Treatment of Wryneck—Arnold reports fifty-six cases of torticollis in which operation was performed, fifty one of which were followed up. Sixteen patients were operated on between 1919 and 1924 by the Volkmann method of open tenotomy of the lower ends of the sternocleidomastoid muscle. From 1924 to 1931 forty were operated on by the method of Mikulicz, which consists of partial or complete extirpation of the sternocleidomastoid muscle. A number of the patients came at a late stage after the tenth year of life, when irreparable secondary changes have taken place. In forty-three cases in which the obstetric history could be obtained twenty-five had been breech, seventeen occipital and one posterior parietal presentations. Much stress is laid on the postoperative treatment. This consists of massage of the scar, passive and active exercises of the neck and certain special gymnastic procedures. The functional result after the Mikulicz operation was far superior to that of tenotomy. There

were two failures after fourteen tenotomies and only one failure after thirty-five Mikulicz operations. Since 1931 the author has had experience in nine cases with the method advocated by Lange and by Tillaux. It consists of sectioning the upper end of the sternocleidomastoid muscle just below the mastoid process. The advantages claimed for it are (1) a scar that can be concealed by the hair, (2) preservation of the contour of the neck and avoidance of a depression just above the clavicle, (3) better functional result, and (4) a smaller operation without accidental injuries (jugular vein, the accessory nerve). Of the nine cases, seven presented excellent results, one was improved and one was a failure. The author feels that in the future he will prefer the Lange-Tillaux procedure for the cases belonging to the group 1 of Lorenz as well as for the milder cases of the group 2 of Lorenz up to the age of 15 years. Past this age the choice of the procedure must depend on the severity of the case. For the more severe cases, partial or complete extirpation of the sternocleidomastoid muscle holds out the prospect of a better functional result. Better results may be expected with individualization of the operative method rather than by adhering to any one scheme.

Subphrenic Abscess—Janz reports the incidence of subphrenic abscess in the Frankfurt University clinic for the last nine years. The etiology is variable, the most common cause being some inflammatory intra-abdominal process. In about 10 per cent of the cases the etiology remains obscure. There is little to support the hematogenous infection in the case of a history of furuncle or other distant inflammatory process. In their material appendicitis gave rise to relatively few cases of subphrenic abscess, five after 2,452 operations, or 0.25 per cent. The incidence of abscess in the pouch of Douglas was likewise lower than that given in most statistics. The author ascribes this to the accepted principle of the Frankfurt clinic of immediately operating in appendicitis at every stage. In cases complicated by abscess formation, perforation of the appendix or total gangrene of the appendix, extensive drainage was resorted to. The lapse of time between the original disease and the development of the subphrenic abscess is a matter of months or years. The interval in one of their cases was seven years. The diagnostic difficulties are many and are due to the presence of various symptoms, none of which are pathognomonic. In obscure cases the history is important. Roentgen study plays the most important part. The high position and partial or total immobility of the diaphragm with slight displacement of the cardiac shadow is quite suggestive. In gas-forming abscesses, which constitute about one fourth of all cases, the roentgenogram is even more pathognomonic. It shows a collection of gas under the cupola of the diaphragm with a fluid level below. The existence of a basal pleurisy on the same side renders the roentgen differentiation impossible. Diagnostic puncture carries with it the danger of puncturing and infecting the pleura and is therefore, to be regarded as the last measure to be undertaken only just before the operation. Many authors prefer operative exposure of the subdiaphragmatic space. The treatment is always surgical. One should be governed in the choice of the operative method by the indications in the individual case. Dogmatic adherence to any one method to the exclusion of others is not justified. The author does not share Nather's categorical rejection of

the transdiaphragmatic transpleural approach. Generally speaking the method that offers the best opportunity for efficient drainage is best suited for the individual case. They have lost only one patient of fifteen who were operated on. Contrary to the general view spontaneous healing of the subphrenic abscess may take place, as proved in one of their cases. The author is inclined to regard the principle of an immediate operation in every stage of appendicitis as of prophylactic importance in the incidence of this form of subphrenic and other residual abscesses.

Histologic Differences in Healing of Fractures—Goetze and Brackertz demonstrated histologically in animal experiments that the mere operative act of exposing the fracture, without an attempt at reduction and fixation, regularly interfered with the process of normal consolidation. The rapid metaplasia of the early fibroblastic tissue in temporary osteoid and chondroid callus is much delayed. The wound developed an increased acidity. These disturbances in consolidation are increased by injury to the periosteum. Postponement of the time of operation to a later date when sufficient temporary callus is present diminishes the disturbance in metaplasia. The author demonstrated in histologic studies that the ends of the fragments in every fracture undergo a necrosis and a breaking down of the bony structures. The histologic studies of the closed healing and operative healing of fractures furnish a basis for preference in favor of the conservative methods. These can act as guides when the advantages of exact anatomic reduction require osteosynthesis. The not too early nor too late operation is of great importance. The operative procedure should be limited to a few essentials. One should avoid making an exposure or, if necessary, be content with the least exposure. One should further avoid injury to the periosteum, periosteal callus and periosteal blood vessels. It is preferable not to leave a foreign body in the wound and, if advisable only the smallest foreign body susceptible of being removed through a small incision.

Hematogenous Tuberculous Infiltrates—Held maintains that the tuberculous pulmonary focus no matter whether of bronchogenic or of hematogenous origin is highly inflammatory at the beginning of the reinfection but he considers it an unproved generalization to assert that every tuberculous focus begins (independent of the phase of infection) as an "infiltrate" (he considers this as merely a roentgenologic term). The mode of dissemination indicates only that hematogenous infections produce as a rule acute manifestations while the bronchogenic disseminations may produce highly inflammatory new foci (daughter infiltrates) or chronically granulating acne-nodose foci. The author shows that the hematogenous infil-

trates are not of a uniform character and that they should be estimated not on the basis of the inflammatory character but on the immunobiologic basis. They can be differentiated into those that present a manifestation of hypersensitivity (round infiltrates) and those that are the result of a disturbance in the defense action. The author illustrates the two groups with case reports.

So-Called Tuberculous Rheumatism—Raschewskaja and her associates call attention to the fact that a number of investigators have advanced evidence that relations exist between certain forms of polyarthritides and tuberculous infections, but they do not agree on the points on which a definite diagnosis can be based. The authors report three cases. They do not agree with Poncet who considers tuberculous every polyarthritides in a patient having tuberculosis. On the contrary, in rheumatic or arthritic disorders, in which bacteriologic and histologic proofs of a tuberculous nature are absent, they consider the diagnosis tuberculous rheumatism justified only if the following points are fulfilled: (1) absence of other infections, (2) the development of a polyarthritides in connection with the acute flare up of the primary, specific tuberculous process or the further development of a fungus or a white tumor, (3) refractoriness to treatment with salicylates, (4) absence of endocarditis, and (5) to a certain extent the positivity of the tuberculin reaction. The authors realize that objections may be made to their cases because of the absence of histologic and bacteriologic proofs, but they hope that their report will draw the attention of physicians to this form of polyarthritides. They think that, if this form is recognized early enough, suitable therapeutic measures will be resorted to, such as climatic cures, roborating treatment, quartz lamp irradiation and, occasionally, tuberculin therapy.

Exudative Pleurisy and Allergy—Furlan shows that two factors are of primary importance in the development of exudative pleurisy: the allergic condition of the organism and the quantity of bacilli that reach the pleural cavity. Both factors may exist in various degrees and thus numerous combinations are possible, which explains the great diversity in the clinical picture of exudative pleurisy. Other factors may also play a part, such as the virulence of the bacillus and the constitution of the patient.

Symptomatology of Persistent Bronchial Fissures. K. H. Link. p. 171.

Surgical Treatment of Exophthalmic Goiter—Von Haberer has operated on 103 patients suffering from hyperthyroidism. He is convinced that in some cases of exophthalmic goiter thymus hyperplasia is an important factor, which explains why some patients are not cured by a most extensive thyroidectomy. Geographic variations undoubtedly play a part. The general picture of exophthalmic goiter in the Rhineland is much graver than in the Austrian Alpine territory. The author observed that the thymus plays a much less important part in Rhine Province than in the Austrian Alps, particularly in Tyrol. Considering his mortality figures in cases in which thyroidectomy alone was performed the author emphasizes that, with the exception of one purely cardiac death, all showed on postmortem examination a large hyperplastic thymus which was considered by the pathologist to be the cause of death. Of four patients who died after the combined operation of thyroidectomy and thymectomy, it was established on postmortem examination that considerable amounts of the thymus were left behind in three. The author summarizes his surgical indications as follows: 1. When the symptoms point mainly to the disturbance of the thyroid he performs a radical thyroidectomy. When palpation in the region of the jugular notch reveals fatty tissue in the place of the thymus, nothing further is done. 2. When palpation in the region of the jugular notch reveals a

hyperplastic thymus rich in lymphoid tissue, he removes as much as possible of the thymus. 3 Thymectomy alone is done in the rare cases of exophthalmic goiter in which no enlargement of the thyroid gland is present and in which the thymus acts as the stimulating agent.

Anatomy of Cervical Portion of Vertebral Column—According to Rathcke, the normal physiologic configuration of the cervical portion of the vertebral column is one of lordosis. Deviations from this configuration are the result of disintegration or of fibrous transformation of the intervertebral disks. The lordosis is due to the disks being wedge shaped, with their nuclei placed considerably forward. The cervical vertebrae differ in form from the rest of the vertebrae. Their surfaces up to the seventh year are almost flat. Past this age, the lateral segments of the vertebrae begin to rise so as to surround the lower aspect of the vertebra above. The lateral ligaments do not run along the lateral protuberances but about the base of the vertebra. The author was not able to recognize on macroscopic and microscopic examination the existence of lateral joints described by Luschka. After the second decade there appear fissures in the lateral segments of the vertebrae. This was erroneously construed by Giraudi as spondylosis deformans of the lateral articulations. Cartilaginous rests of disintegrated intervertebral disks are to be found in the epistropheus up to an advanced age. This is regularly observed up to the seventh year and was observed in a child aged 11. The absence of a nucleus is the peculiar feature of such a disk. Calcifying intervertebral disks are likewise seen in the sacral bone. These cartilaginous rests probably favor the occurrence of fractures. The intervertebral spaces in children appear in the roentgenogram as slits. The most frequent alteration observed in the intervertebral disks of the cervical portions of the vertebral column is disintegration. This affects with the greatest frequency the fifth and sixth disks. The process may be so pronounced as to lead to osteochondrosis. Crumbling leads to spondylosis deformans. In high grade spondylosis deformans the lateral eminences of the superior aspect of the vertebrae spread so as to become flat.

Anterior Hypophysis and Calcium Content of Blood—Hoffmann and Anselmino demonstrate in experiments on dogs and rats that the calcium content of the blood of these animals increases under the influence of extracts from the anterior lobe of the hypophysis. They detected also that the substance is thermolabile. In parathyroprival rats, however, extracts of the anterior lobe of the hypophysis did not produce an increase in the calcium content of the blood. On the basis of these observations and of the formerly reported histologic changes in the parathyroids, the authors conclude that the increase in the blood calcium effected by the extracts of the anterior hypophysis is due to an activation of the parathyroids and to an increased secretion of parathyroid hormone.

Parathyrotropic Action of Extracts of Anterior Lobe of Hypophysis—Anselmino and his collaborators describe the

action of extracts of the anterior lobe of the hypophysis on the histologic picture of the parathyroids of rats. They found that by means of extracts of the anterior hypophysis it is possible to produce characteristic morphologic changes in the parathyroids. These changes are evidenced by an enlargement that amounts to from two to three times the original size, by a predominance of the clear cells over the dark cells, by absence of the oxyphil cells, by the disappearance of the intracellular fat granules and by a strong vascular reaction. These changes are interpreted as signs of an activation of the parathyroids. The authors are as yet unable to decide whether these changes are the result of a specific parathyrotropic substance of the anterior lobe of the hypophysis.

Anesthesia, Particularly in Abdominal Operations—Kirschner in abdominal operations has found it helpful to combine spinal and local anesthesia. He adds the local infiltration anesthesia to the spinal girdle anesthesia. For the administration of the local anesthetic he recommends a high pressure apparatus that introduces the anesthetic under a pressure of three atmospheres. Within a few seconds a large area can be infiltrated. The anesthetic fluid saturates the interstitial tissue and is brought into close contact with the finest nerve elements, and the anesthetic is effective at once. The author illustrates the entire procedure of the combination of spinal girdle anesthesia with high pressure local anesthesia as it is done in a case of gastric resection. He recapitulates the advantages of high pressure local anesthesia over the usual administration by means of the hand syringe. He employed the method in approximately 5,000 cases without experiencing a single serious impairment, and now he uses it in all abdominal operations.

Cerebral Tumors—Pette differentiates between extracerebral and cerebral tumors. In discussing the extracerebral tumors he reviews particularly the symptomatology of meningiomas but also discusses tumors of the hypophysis. He reviews the symptoms of malignant gliomas. There is generally a change in the personality of the patient, which becomes manifest as a shallowing of all psychic reactions. Unnatural drowsiness is another symptom. The causal factor of these manifestations is probably cerebral swelling. The local symptoms are dependent on the site of the tumor. There may be jacksonian attacks, or if the internal capsule and the basal ganglions become involved, spastic or flaccid hemipareses may develop. The fact that the malignant glioma does not tolerate interventions but rather reacts to them with acute exacerbations of the sympathetic disorders induced the author to refrain from operative interventions. The patient should be left to his fate and the treatment should be limited to symptomatic measures. Even a lumbar puncture may have disastrous results. If the severity of the general symptoms necessitates a depressive intervention which, however, is only rarely the case, trepanation should be done at the site where the tumor is suspected. Should an operation be decided on, which is often the case in the event of doubtful diagnosis, the soft tumor should be removed as extensively as possible, so as to make room for an eventual postoperative edema. The author thinks that in cases in which the centers of the intellectual sphere are involved a surgical intervention should be dispensed with, for a successful intervention would mean only a prolongation of suffering for the patient. After discussing benign gliomas, infratentorially developing tumors and growths of the cerebellum, he evaluates various methods of physical examination, including ventriculography and arteriography, but he emphasizes that the clinical methods of examination are of primary importance.

Benign Tumors of Breast and Cancer—Control examinations of forty-five women, in whom a benign tumor of the breast had been removed, convinced Hogenauer that the solid tumors are hardly ever the cause of cancer development. The cystic formations, that is, diffuse fibrosis and cystic breast, likewise have no tendency to carcinoma formation. However the author considers it inadvisable to group cystadenoma in this respect with the other cyst formations, because of four patients, in whom a cystadenoma had been removed, two developed a malignant growth in later years. From this the author concludes that the cystadenoma has to be judged carefully in regard to its tendency to malignant degeneration. Since the entire gland apart from the palpable tumor is often diseased, amputation of the breast is advisable but, if only the nodule has been extirpated and the histologic examination proves it to be a cystadenoma, the patient should be kept under constant control. Since there are transitional forms between the cystic formations of the breast and the examination does not reveal the exact character of the neoplasm the author considers it advisable to adhere to the rule that in doubtful cases extirpation should be resorted to.

Specific Therapy of Erysipelas—Neuber employed convalescent serum in thirty-six cases of erysipelas and gained the impression that the defervescence and the disappearance of the toxic and of the local symptoms are effected more rapidly and completely than was the case in patients who received non-specific treatment. Only one of the thirty-six patients who received the specific treatment died, and this one had sepsis and phlegmon and was moribund when he arrived at the clinic. The author asserts that the administration of the convalescent serum produced no fever reaction, at least, the existing fever was not increased. The serum was administered by intragluteal and occasionally by subcutaneous injection. The usual dosage was from 20 to 40 cc, depending on age, weight and other factors. In the majority of cases two administrations were sufficient (from 50 to 80 cc), and in mild cases sometimes one. The author thinks that convalescent serum should have a leading place in the treatment of erysipelas. He ascribes the favorable results to the action of the specific protective substances that are present in the convalescent serum. Undesirable secondary manifestations, such as shock or delirium, were never observed.

Radium Treatment of Menopausal Hemorrhages—Martius gives the following reasons that induced him to replace the roentgen treatment of menopausal hemorrhages by radium treatment: the more prompt hemostatic effect, the greater simplicity of the method and the fact that the intoxication and the deficiency symptoms are less severe after radium. He con-

siders from 1,800 to 2,000 milligram element hours administered in from twenty to twenty-two hours with 90 mg of radium element the best mode of application. The use of smaller amounts of radium is inadvisable because the radium must remain longer in the uterus, a factor that increases the danger of infection. The author proceeds generally as follows: After curettage or exploration of the uterus, the curetted material is examined under the microscope and from three to four days later the radium is introduced, usually by means of a brass container of 13 mm wall thickness and 35 cm length. This method of application was employed by the author for eighty-seven women between the ages of 40 and 57. It was successful with all but three and in one of these cases the diagnosis had been erroneous in that a small submucous myoma had been overlooked. That the effects of the treatment are permanent is evidenced by the fact that in all but two of the eighty-four the amenorrhea still persisted, after the treatment had been completed for more than eighteen months.

Elective Therapy of Carcinoma of Uterine Cervix—Von Mikulicz-Radecki points out that, since the elective therapy employs both surgery and irradiation, the old dispute about the advisability of the one or the other is avoided. Many patients are surgically treated, however, not all for whom a surgical intervention would be possible but only those for whom the operation promises favorable results. The patients who have been operated on receive roentgen treatments, or, eventually, the operation may be preceded by irradiation. Other patients are treated only with radium and roentgen rays. The author illustrates the results of the elective therapy of carcinoma of the uterine cervix in a statistical report comprising 5,500 cases. Combined surgical and ray treatment was given in 34.8 per cent of the cases, and the other patients were treated only by radiation, with the exception of 5 per cent of the cases that were entirely incurable. Complete cure was obtained in 24.5 per cent of the cases, that is, about every fourth patient recovered. This is a rather favorable rate in such a large material, although some clinics have obtained 36.5 per cent of complete cures. The author concludes that the elective therapy is the method of choice. To obtain these results from 20 to 40 per cent of the patients should be subjected to radical operation, in the course of which it is advisable to remove considerable portions of the parametric, paravaginal and pararectal tissues, together with portions of the vagina, for these are the regions to which cervical cancer spreads first. This extensive resection presents the main advantage of the radical operation over exclusive ray treatment. Simple extirpation of the uterus is entirely inadequate and therefore inadvisable. The removal of the iliac and the hypogastric lymph nodes is of minor significance. Abdominal or vaginal radical operations give about the same final results, but the primary mortality rate is lower in case of vaginal radical amputation, and consequently the author considers this method the better one. Surgical treatment should be limited to the cases that are still well operable, because an incomplete operation does more harm than good. As a routine measure, the operation should always be followed by roentgen treatment. Radium treatment is advisable in cases in which complete surgical removal of the cancer is not certain. Preoperative irradiation can be resorted to in cases that are to be made operable, while in carcinomas that are operable in the beginning, valuable time may be lost by preoperative irradiation. Intensive radium and roentgen treatments should be administered in all inoperable cases.

Blood Pressure Reducing Action of Cancer—Feldweg kept records of the blood pressure of more than 300 patients having cancer and found that the blood pressure is lower than in those who have been cured. Following successful treatment, the blood pressure increases on the average about 15 mm of mercury, and this increase persists if no relapse sets in. However if the cancer continues to grow, the blood pressure remains low or decreases still further. The blood pressure reducing action must be effected by the cancer as such, for observations revealed that it is not dependent on the factors of age, the menopause or cachexia. The author thinks that in cancer patients the regular measurement of the blood pressure is a valuable aid in prognostication and in the recognition of a relapse.

Annual and Mensual Morbidity Rate at Ophthalmologic Clinic in Helsingfors from 1912 to 1926 S Werner —p 1126

*Mycosis Fungoides Nine Cases N E Wilen —p 1144

Papilloma of Pelvis of Kidney—Jansson says that pyelography may be of greater importance in the diagnosis of papilloma of the renal pelvis than in tumors of the renal parenchyma, in which it frequently merely confirms a certain clinical diagnosis. Further, since papilloma of the bladder may be a secondary manifestation of a papillomatous primary tumor in the renal pelvis and can be successfully treated only if the underlying cause is recognized, the importance of improved roentgen diagnosis in this field is evident.

Mycosis Fungoides—Wilen states that seven of his nine cases are of the classic Alibert-Bazin type, one is perhaps an example of primary mycosis fungoides, and one is regarded as a fungoid granuloma.

*Simple Hemorrhagic Proctitis and Proctosigmoiditis T E H Thaysen —p 1181

*Acromioclavicular Luxation H K Lassen —p 1196

Simple Hemorrhagic Proctitis and Proctosigmoiditis—Thaysen says that this ailment, while confused with other forms of proctitis and particularly with ulcerative, suppurative colitis, is rectoscopically, microscopically and clinically characteristic. In simple hemorrhagic proctitis and proctosigmoiditis the mucous membrane, when the inflammation is fully developed, is bright red, moist, glistening and finely granulated. Hyperemia and hemorrhages in the tissues stamp the microscopic picture. The graver cases seem often to start with a mild proctitis as the only symptom and maintain this stage for years, until a sudden spread of the inflammation in the rectum possibly into the sigmoid flexure, causes symptoms that send the patient to the physician. Certain diagnosis can be made only by rectoscopy, which also shows the extent and degree of inflammation. In chronic ulcerative colitis the course is afebrile except in the few cases with acute onset, the general condition is little affected, anemia rare, constipation the chief functional intestinal disturbance, and prognosis good. Treatment is partly local, partly general. The immediate results of treatment in nineteen cases were excellent, the late results, observed up to four years, relatively good, recurrence usually mild, was seen in most cases but as a rule disappeared after a short treatment. Three cases are described in detail.

Acromioclavicular Luxation—Lassen's after-examination in thirty-one cases of certain acromioclavicular luxation treated from 1920 to 1931 (twenty-seven conservatively, four surgically) showed that sixteen patients were free from symptoms, four of these without any abnormality, and that in the fifteen with subjective symptoms objective changes were noted. About 16 per cent of the patients were unable to do their previous work. Comparison is made with forty-nine similar cases from the Workman's Insurance Commission treated during the same period. Both materials indicate that in pronounced luxation operative procedure is called for. The question, the author finds, is how to treat the cases of luxation of about 1 cm in some of which conservative treatment gives unsatisfactory results.

*Clinical Investigation on Symptoms of Intoxication in Lacquering with Duco M Ellermann and J Jakobsen —p 1213

Removal of Intrathoracic Neurofibroma of Size of Fist in Girl Aged 9 J Gravesen —p 1221

Symptoms of Intoxication in Duco Lacquering—Following a case report Ellermann and Jakobsen discuss the acute and chronic symptoms due to working with duco lacquer, the former consisting of sudden sleepiness, tired feeling, dizziness, irritation of the mucous membrane and sometimes, dyspeptic symptoms, and the latter of irritability. In prophylaxis strong ventilation and possibly, intermissions to be spent in the open air are advised. The intake of milk and daily use of eye wash and nose ointment are subjectively effective against the irrita-

tion of the mucous membrane. The quality of the thinner is believed to be of especial importance, as certain thinners are more disturbing than others, and systematic analysis of the available thinners with withdrawal from the market of the inferior sorts is suggested.

76 1237 1252 (Dec 28) 1933

*Disorder of Nervous System After Serum Injection F Wulff —p 1237

Disorder of Nervous System After Serum Injection—During the serum sickness following prophylactic injection of antitetanus serum in the first case reported, paralysis of muscle of the arm appeared. In the second case, treatment of tetanus with antitetanus serum was followed by serum sickness and four weeks later, by myelitis with paralysis of the lower extremities. The neuritis in the first case is definitely ascribed to the serum and it is assumed that the involvement of the central nervous system in the second case was due also to the serum or the serum sickness. Wulff emphasizes that this disturbance of the nervous system is so rare that it does not limit the indications for the use of serum.

Cod Liver Oil Lesions and Their Healing Tendency—Andersson followed the development and the healing of the lesions produced in white mice by giving 3 cc of cod liver oil per kilogram of body weight daily. Pigment and vacuole degeneration, transformation of muscle cells into connective tissue and sometimes degenerative fatty infiltration and calcareous incrustation were found in the heart. In the diaphragm, there were pigment degeneration and sometimes waxy degeneration and calcareous incrustation in four cases of diaphragmatic hernia. Conglomeration and pigmentation degeneration of the cells of the medulla appeared in the suprarenals, parenchymatous degeneration and calcareous incrustation were sometimes seen in the kidneys and pigment degeneration, sometimes stasis and degenerative fatty infiltration and, in four cases, necrosis in the liver. The lesions usually appeared independently of the diet but more rapidly with incomplete diet. Some lesions healed well, healing of pigment degeneration, calcic incrustation and degenerative fatty infiltration were not observed. There was never complete restitution.

Diet and Regeneration of Injuries to Heart Muscle—Agdahl's electrocardiographic and histologic studies in white mice with heart lesions produced by cod liver oil treatment seem to him to show that regeneration and restitution of the muscle cells of the heart can occur with more conspicuously practical results if a complete diet is given during the period of healing. The results of healing are especially notable if an incomplete diet is used during the time of cod liver oil treatment and a complete diet after the end of the treatment.

Nerve Fibers in Roots of Spinal Nerves—Arnell's results confirm Ranson's observations that nerve fibers free from myelin sheath are present in the roots of the spinal nerves in man and show that such nerve fibers appear in the roots of all spinal nerves, being numerous in all dorsal roots. In a rather slight man the number of nerve fibers in the roots of the spinal nerves on the left side was 952,777 in the dorsal roots and 197,256 in the ventral roots. In the same right-handed person the number of nerve fibers on the right side, both in dorsal and in ventral roots, was greater than on the left side.

THE INCIDENCE AND PATHOGENESIS OF DEGENERATIVE ARTHRITIS

CHESTER S. KEEFER, M.D.

AND

WALTER K. MYERS, M.D.

BOSTON

In determining the incidence of chronic degenerative arthritis, three general methods may be used: 1. The various joints may be examined post mortem. 2. Roentgen examination of the joints may be made. 3. The number of patients having symptoms referable to their joints may be determined. Of these three, the first is by far the most satisfactory. It is generally known that anatomic changes may be present with few symptoms and, unless there are evidences of irregularities at the margin of the joint surfaces or a decrease in the joint space, roentgen examinations of joints may fail to demonstrate changes. In order to gather more precise information regarding the incidence of degenerative arthritis, we have examined approximately 150 knee joints obtained from patients dying of a variety of diseases. Aside from these observations, we have compiled from the literature the results of anatomic studies of the joints as found at necropsy by a number of observers.

In a previous paper, we pointed out that in 100 knee joints anatomic changes were observed in 81 of the cases. Lesions were observed increasing in frequency with advancing age and the areas showing the most striking lesions were those subjected to the greatest pressure, movement, weight and trauma. The following parts of the joints were involved in the order of frequency: the patella, the intercondyloid areas of the femur, the condyles of the tibia and finally the condyles of the femur. Similar observations have been made by Heine,¹ Rimann-Clark,² Beitzke,⁴ Bauer and Bennett-Meyer⁶ and Keyes.⁷ Figure 1 illustrates the prevalence of the changes observed in the knee joints (A) by ourselves and (B) by Heine. It is seen that the curves are similar in form. That of Heine is smoother in outline owing to the wider scope of observations. It is obvious that in both instances, the extent

of the condition increased with advancing age. Rimann recorded changes in 67 per cent of 100 patients ranging in age from 15 to 80 years. Beitzke found changes in the joints of 178 of 200 bodies examined. He studied the knee, metatarsal, hip and shoulder joints. He observed that the frequency of arthritic changes increased with age, so that between 20 and 40 years 60 per cent of the cases showed defects, between 40 and 50 years 95 per cent, and 100 per cent of older persons.

What has been said of the knee joint applies to other joints and, particularly, to the joints of the spine. The most exhaustive and thorough anatomic study of the range of degenerative arthritis of the spine (spondylosis deformans) is that of Schmorl and Junghans,⁸ who examined 4,253 spines at necropsy. We have constructed a chart from their data, and it requires little comment (fig. 2). It is seen that the changes increased with age. Heine has made similar observations on 1,000 cadavers. The incidence of degenerative arthritis of the spine as recorded by him was somewhat lower than that recorded by Schmorl and Junghans and is due to a difference in the number of cases and to the criteria used in recording the presence or absence of exostoses. Similar observations on the extent of spinal changes have been made by roentgen examination by Gantenberg⁹ and Garvin.¹⁰ They all agree that the condition increases with age.

Aside from the knee and spine, other joints such as the sternoclavicular joint, acromioclavicular and sacro-iliac joint have been studied by Ely,¹¹ Sievers,¹² Zollner¹³ and Smith-Petersen.¹⁴ Heine has examined, in addition to the joints mentioned, the hip, shoulder, elbow, metatarsal and sternoclavicular joints. The results of the observations of Sievers on the acromioclavicular joint of seventy-seven patients and of Zollner on the sacro-iliac joint of sixty patients are shown in figures 2 and 3. Here again it is seen that the curve rises with age. In figure 4 the results of Heine's studies are recorded for all the joints examined, and the results require special comment. While it is accepted that the percentage of cases showing changes in the joints increases with age, there are differences in the

frequency with which these changes are observed in the different joints. The knee, the metatarsal the acromioclavicular, the elbow and hip, and the spine showed changes more frequently than the sternoclavicular and shoulder joints. These differences are probably accounted for in part, at least by the variations in weight, pressure and trauma. Thus the knee is subjected to more or less constant movement, weight and pressure and is therefore traumatized more frequently than other joints. Thus, from our own observations and those of others it is sufficiently

Fig. 1—Incidence of anatomic changes in the knee joint with advancing age. A authors' series of 100 cases. B Heime's series of 1 000 autopsies.

Fig. 2—Observations of Schmorl and Junghans on the incidence of spondylosis deformans with advancing age and of Sievers on the incidence of changes in the acromioclavicular joints. 1 female patients with spondylosis deformans. 2 male patients with spondylosis deformans. 3 patients with changes in the acromioclavicular joints.

clear that degenerative arthritis increases in frequency with advancing age. It is true regardless of the movable joints examined and must be considered in any study of the prevalence of the condition.

Since this fact has been established, it is necessary to consider factors other than age which influence its frequency. A few of the more important ones are occupation, static deformities and trauma.

It has been long appreciated that occupation is of the highest importance in determining the site and extent of degenerative changes in the joints. Lane¹⁵ emphasized this point of view in 1886 and since then his observations have been repeatedly confirmed and amplified. In a most interesting study of the relationship between occupation and degenerative arthritis, Fischer¹⁶ and other continental investigators have shown that arthritis of the elbow, shoulder and metacarpophalangeal joints is extremely common in men who use compressed air hammers. This was especially true of workers using such tools after a period of from three to ten years. Dr. Joseph L. Miller has informed us that he has observed similar cases and that many of these patients develop Raynaud's syndrome. Gntenberg has likewise pointed out that, while spondylosis deformans increases with age, it is commoner in laborers subjected to heavy work, such as miners and farmers, than it is in factory workers and mechanics. In his observations women showed fewer changes than men. It is essential, there-

fore, to consider the patient's occupation in the evaluation of joint changes that are seen in degenerative arthritis.

Aside from occupation, it has long been known that static deformities are commonly followed by degenerative changes in the joints. Preiser¹⁷ was one of the foremost advocates of this view, and degenerative changes are seen frequently in the hip, knees, ankles and feet of persons with flat feet, bow legs, knock knees, or coxa vara or valga. The unequal distribution of weight, together with the increasing amount of trauma to certain parts of the joints invariably leads to degeneration of the cartilage and damage to the underlying subchondral bone.

Another factor for consideration in evaluating degenerative changes is gross trauma. Injury to joints with hemorrhage into the joint cavities, as in hemophilia, is frequently followed by degenerative changes.¹⁸ Fractures extending into the joints and repeated injuries to the joints in patients with disorders of the central nervous system and loss of pain sensation, such as tabes dorsalis and syringomyelia, are the cause of alterations in the joints giving the picture of degenerative arthritis.

Since the incidence of degenerative arthritis will depend on the factors mentioned, the question arises: What is the sequence of events in the evolution of the gross and histologic changes that are observed in these joints? As a result of our observations, we believe that the evolution of the process is as follows: As a result of the aging of the cartilage or gross trauma, it loses its

Fig. 3—Observations of Zollner showing incidence of anatomic changes in the sacroiliac joints of sixty-six patients at different age periods.

Fig. 4—Observations of Heime giving the percentage of cases showing anatomic changes in the various joints with advancing age.

elasticity and becomes split or fibrillated in the vertical plane. Following this change the damaged cartilage no longer protects the subchondral plate of bone from pressure, weight and impacts, in the same way as does

normal cartilage. This leads to compression of the subchondral bone, so that the normal joint line is distorted and the subchondral bone appears thickened (fig 5). When the cartilage has been completely lost over the surface and pressure and movement of the exposed bony surface continue, the bone becomes very dense and the surface highly polished. Actual fractures of the bony trabeculae may occur, and when it does there is an attempt on the part of the bone to repair the damage. In some cases new bone is formed in these fractured areas, and islands and nests of cartilage and small cystlike areas are seen to appear in the medulla of the bone.

Fig. 5—Section from the patella showing fibrillation of the cartilage and alteration in the contour of the normal subchondral bone with compression and thickening

At the margins of the joints, so-called exostoses are seen. It is commonly stated that these bony excrescences arise from the subchondral bone. In other words, they are bony outgrowths. From our observations we have not been able to convince ourselves that this is true. In some instances the periosteum may show bony proliferation covered by new cartilage at the insertion of tendons, but the usual projections at

Fig. 6—Section from femoral condyle showing projection of bone and cartilage over the edge of the condyle—a so-called exostosis or lipping

the joint margins which are so common have a different origin. In our experience, we have not observed evidence in the histologic sections that these areas are overgrowths of bone. They appear to arise as a result of changes in the joint line, and in some cases the normal joint line has been depressed and flattened so that the edge projects over the margin of the bone like a mushroom. In other instances they simply represent the remnants of joint margin which have been forced outward by constant pressure. This change is best illustrated in figure 6.

SUMMARY

The incidence of degenerative arthritis increases with advancing age. It is more prevalent in certain occupations, when there has been injury to the joint surfaces, and when static deformities are present. The anatomic changes can be explained on a basis of injury to the cartilage and bone, which follows the wear and tear of the joint structures, and are not due to any particular disease process.

ACUTE APPENDICITIS IN PHILADELPHIA

A REPORT OF THE PROGRESS MADE IN THE
CAMPAIGN FOR ITS REDUCTION

JOHN O. BOWER, M.D.

PHILADELPHIA

The reports of the original and subsequent surveys with a description of the plan for the reduction of the mortality of acute appendicitis, as carried out in Philadelphia, were published in 1927,¹ 1931,² and 1932.³

Dr. J. Norman Henry, director of the department of public health, with the cooperation of Dr. W. G. Turnbull, superintendent of the Philadelphia General Hospital, made this year's survey possible. The Philadelphia County Medical Society, the College of Physicians, the staffs and superintendents of the various hospitals and the Philadelphia Association of Retail Druggists cooperated with the department of public health in the campaign to reduce the time between the onset of symptoms and hospitalization and to prevent the administration of laxatives.

The sticker warning was not distributed to the physicians of Philadelphia as in previous campaigns but, with the help of Drs. E. C. Broom and W. S. Cornell of the board of education, arrangements were made to place them directly in the hands of high school students, with the request that they affix them to the cover of a book they use daily. Appendicitis occurs most frequently between the ages of 10 and 20 years, which explains our reason for selecting the high school group. Short talks explaining the dangers of delay in hospitalization and the giving of laxatives were given to several thousand students. With the cooperation of Dr. Borzel, chairman of publicity of the Philadelphia County Medical Society, an attempt will be made to extend this publicity to both junior and senior high school students.

MORTALITY

Table 1 shows the total number of clinical records reviewed in the past five years, with the number of deaths and the percentage of mortality.

In 1931 the decrease in mortality percentage was 0.42, the surgeons of Philadelphia contributed largely to the diminished mortality by their improved management of spreading peritonitis, in which there was a decrease of 1.81 as compared with 1930 (table 2). The percentage of peritonitis cases admitted each year was practically the same, but the delay in hospitalization in 1931 was 4.63 hours longer. We expected little or no progress during the past year, because it was impossible to carry out as intensive a campaign as in previous years.

From the Philadelphia General Hospital		
1	Bower, J. O.	Am. J. M. Sc. 174: 225 (Aug.) 1927
2	Bower, J. O.	Acute Appendicitis, J. A. M. A. 96: 1461 (May 2) 1931
3	Bower, J. O.	Mortality of Acute Appendicitis, J. A. M. A. 99: 1765-1767 (Nov. 19) 1932

During 1932, however, six factors entered into the diminished mortality

- 1 A marked increase in the number of cases over preceding years
- 2 Earlier hospitalization
- 3 A diminished number of cases of peritonitis
- 4 A diminished number of cases of spreading peritonitis
- 5 An improvement in the management of spreading peritonitis by the surgeons of Philadelphia
- 6 Less frequent administration of laxatives

INCREASE IN THE NUMBER OF CASES

The clinical records of the same hospitals examined in previous years were analyzed. While there was a change in the personnel of those abstracting the charts, the supervision of the abstracting, the segregation of the pathologic observations and the compilation of the statistics were carried out by the same persons.

The marked increase in the number of cases was in the ward group. In one of our public institutions the

TABLE 1—Mortality Record for Five Years

Year	Number of Cases	Deaths	
		Number	Per Cent
1928-1929	5,121	306	5.97
1930	3,093	149	4.81
1931	3,142	178	5.66
1932	3,546	122	3.44
Totals	14,904	715	4.79

increase was 44 per cent over 1931. In hospitals in which both private and ward patients were operated on, however, the increase was decidedly less. The economic situation no doubt made it easier for the family physician to hospitalize patients earlier, especially the unemployed, who were admitted as ward patients.

EARLIER HOSPITALIZATION

There is a varying relationship between the time that elapsed between the onset of symptoms and operation and mortality. For example, the reduction in time in the 1930 series over the 1928-1929 was 23.92 per cent, and the mortality was reduced 24.1 per cent. Earlier hospitalization undoubtedly has a bearing on the decreased mortality, but the close relationship between the aforementioned series does not always exist. For

TABLE 2—Diminished Number of Cases of Spreading Peritonitis

Year	Number of Cases of Appendicitis	Number of Cases of Spreading Peritonitis	Per Cent of Cases Admitted	Number of Deaths from Spreading Peritonitis	Mortality
1928-1929	5,121	608	11.87	237	38.9
1930	3,093	412	13.32	124	26.2
1931	3,142	491	15.62	170	24.4
1932	3,546	457	12.89	101	22.1
Totals	14,904	2,118	14.21	582	27.47

instance, in 1931 the reduction in time and mortality as compared with 1928-1929 was 12.23 per cent and 26.46 per cent, respectively, in 1932 19.16 per cent and 42.7 per cent as compared with 1928-1929.

From table 3 it will be noted that there is an increase in the mortality of those admitted within twenty-four

hours. This is due in part to the increase in catastrophes, ten in number, six of these patients were admitted to the hospital within the first twenty-four hours. This group included one anesthetic death, two deaths from acute cardiac dilatation, one from auricular fibrillation and one each from coronary and pulmonary embolism.

TABLE 3—Relation of Time of Hospitalization and Mortality

	Admitted Within 24 Hours			Admitted Within 48 Hours			Admitted Within 72 Hours			Admitted After 12 Hours		
	Recoveries	No.	Deaths	Recoveries	No.	Deaths	Recoveries	No.	Deaths	Recoveries	No.	Deaths
1928-1929	1,643	42	2.49	1,648	104	5.93	628	74	7.92	896	106	10.8
1930	963	24	2.49	1,143	47	3.05	414	31	6.97	451	47	9.44
1931	930	12	1.27	1,117	48	4.12	403	28	6.49	554	50	8.93
1932	1,149	18	1.54	1,191	50	4.01	518	18	3.44	563	36	6.4
Totals	4,660	96	2.06	4,102	249	4.88	1,963	131	6.67	2,464	239	9.4

Two patients died from internal hemorrhage, one in the seventy-two and one in the ninety-six hour group. The catastrophe is always a factor in mortality. In most instances it is unavoidable. Other factors that have a bearing are the number of surgeons operating (306 in the 1932 group) and the constant change in personnel.

The forty-eight hour group is by far the most interesting to study—interesting because the percentage of mortality has been almost constant. The average mortality for the past three years has been 4.03 per cent, in 1932 it was 4.01 per cent. If one looks for the cause of this it is not necessary to go far. The mortality of spreading peritonitis in the forty-eight hour

TABLE 4—Diminished Number of Peritonitis Cases

Year	Number of Cases	Clean Cases		Average Number Time of Onset of Symptoms and Operation	Number of Cases of Spreading Peritonitis	Number of Local Peritonitis	Mortality per Cent

group over a period of four years has been practically the same. The decrease in mortality is in the groups admitted after the second day and is due to the better management of spreading peritonitis.

DIMINISHED NUMBER OF PERITONITIS CASES

Table 4 shows earlier hospitalization, an increase in the number of clean cases, a decrease in the number of peritonitis cases and a lowered mortality.

Of 14,904 patients admitted to Philadelphia hospitals, 2,118 had spreading peritonitis and 582 died, a mortality of 27.47 per cent. It is fair to assume not only that these figures, to be of any real significance, must represent the results of an accurate analysis of the clinical records reviewed but also that the analysis must be identical each year. In our own behalf we wish to call the reader's attention to the third column in table 2 under "per cent of cases admitted." During the five years the average percentage was 14.21, the greatest

variation from this average occurring in 1932 (1 32), the least, in 1928-1929 (0 67) This I believe is a legitimate variation The segregation of the clinical group spreading peritonitis is so important that I am including a brief abstract of how it is done

The segregation of the spreading peritonitis death is not difficult Frequently the autopsy records are attached and invariably the residents' notes are complete When a surgeon definitely states in his operative observations that spreading peritonitis is present, the case is classified as such Notation is made of the presence or absence of drain, temperature pulse, rigidity, leukocytosis, the time between the onset of symptoms and operation and administration of laxatives When the surgeons' or interns' notes are incomplete or indefinite, the notations on the abstract sheet are consulted and used to arrive at a decision as to whether the patient was treated according to the method of Ochsner and whether the appendix was removed or searched for

1931	618	10	1 62
1932	572	5	0 87
	3 817	83	2 50

In the 1931 survey I mentioned that in a definite percentage of patients, diagnosed before or after admission to the hospital as having a local peritonitis, spreading peritonitis developed because of the operation or poor resistance These I have continued to place in the spreading peritonitis group In 1932 the number of cases admitted was approximately 6 per cent less than in the preceding year

IMPROVEMENT IN THE MANAGEMENT OF SPREADING PERITONITIS IN PHILADELPHIA

Prompted by the progress made in the past three years in Philadelphia in the management of spreading peritonitis, I repeat a previous statement with added confidence If a publicity campaign of increasing intensity can be waged against delay in hospitalization and the abuse of laxatives in 1940 spreading peritonitis will be as rare in our Philadelphia hospitals as cases of typhoid fever are today

While earlier hospitalization has played an important part in the reduction of the mortality, diminishing the number of cases of peritonitis admitted, the most prominent feature is the improvement in the management of

spreading peritonitis by the surgeons of Philadelphia During the past two years the mortality has been reduced 4 15 per cent (table 2)

Based on a critical review of the entire group of cases of spreading peritonitis I venture the following explanation for the improvement Surgeons are becoming spreading peritonitis conscious, they are thinking more about it and are approaching the fulminating case of appendicitis more deliberately

Fifty per cent of surgical management is in knowing what not to do and it is because of this that the following suggestion is presented

That the surgical service in our hospitals as it pertains to acute appendicitis be modified to the extent that the

junior members of the surgical group manage the clean cases but that a consultation be held with the chief of service regarding the management of the perforative or suspected perforative case Neither a watchful waiting nor a drastic policy is advocated, but a request that the 12 or 15 per cent of patients admitted to our hospital with spreading peritonitis who have only about one chance in four of living be given the benefit of all that the service affords in the matter of surgical judgment and experience Wisdom in surgery usually increases with experience, but not always The clinical records reviewed showed that a man may spend decades managing spreading peritonitis and still have a mortality of 65 per cent The associate of the surgical service should concentrate on the preoperative diagnosis of spreading peritonitis, his chief should concentrate on management and be willing to pass along to his associates the knowledge he has gained in the managing

Chart 1 shows the mortality curve for 1,661 cases of spreading peritonitis in twenty-eight hospitals of Philadelphia from 1928-1929 to 1931, inclusive The mortality was lowest on the first and seventh days

Chart 2 shows the mortality curve for 2,118 cases of spreading peritonitis in the same twenty-eight hospitals from 1928-1929 to 1932, inclusive, and the seventh day again has the lowest percentage after the first

Of the 9,783 clinical records abstracted during 1930, 1931 and 1932, 4,598, or 47 per cent, gave a definite history regarding the administration of laxatives The percentage for the three years varied slightly, 45, 48 2 and 47 5, respectively Seventy-two per cent of the 4,598 patients, or 3,293, had received a laxative and 202 or one in sixteen, died 1,305, the remaining 28

Chart 1—Mortality curve for 1 661 cases of spreading peritonitis in twenty eight hospitals of Philadelphia from 1928-1929 to 1931 inclusive The mortality was lowest on the first and seventh days

Chart 2—Mortality curve for 2 118 cases of spreading peritonitis in the same twenty eight hospitals from 1928-1929 to 1932 inclusive The seventh day again has the lowest percentage after the first

per cent, did not receive a laxative and twelve, or one in 109, died. Of those who received one laxative, one in eighteen died, of those who received more than one, one in ten died.

Table 5 shows that the number of patients who had not been given laxatives in 1932 was increased by 2 per cent over 1931. The percentage who had received laxatives in 1932 was diminished by 0.71 as compared with 1931.

The number of deaths following the administration of laxatives has gradually decreased. Of those who had been given laxatives in 1930, one in twelve died, in 1931, one in fifteen died, and in 1932, one in twenty died.

Since the time of Hippocrates, people have taken laxatives for the relief of abdominal pain, but even Hippocrates knew, as far back as 400 B. C., that they were dangerous, because he warned that "in sharp disease

and in their beginning, we ought seldom to use a purging medicine."

It is an indictment against the profession to be forced to report that fifty-five physicians prescribed laxatives to fifty-five patients suffering with appendicitis, which resulted in four deaths.

The high mortality of the 1928-1929 group in table 6 is due, as has been previously mentioned, to the placing in this group patients in whom spreading peritonitis actually developed but who on admission were diagnosed as having a local peritonitis. During the past three years these patients have been included in the spreading peritonitis group.

The diminished mortality in 1932 as compared with 1930 and 1931 is due mainly to the actual decrease in the number of cases admitted. In 1930, 20.2 per cent of the patients admitted to hospitals had a local peritonitis, in 1931 there were 19.6 per cent, and in 1932 there were 15.9 per cent. We were unable to find any marked difference in the surgical management of those operated on in 1931 and those in 1932.

2008 Walnut Street

STABILITY OF U S P ETHER AFTER
THE METAL CONTAINER
IS OPENEDHARRY GOLD MD
AND
DAVID GOLD, BA
NEW YORK

While examining a record of the drugs dispensed in one of the hospital pharmacies, we observed that ether was listed under two headings (1) "Ether U S P in 27 pound drums at 11 cents a pound," and (2) "Ether for anesthesia in $\frac{1}{4}$ pound cans at 63 cents a pound." The cost of ether in the small cans was therefore nearly six times as much as that in the large drums, although the latter had been filled with ether which complied with standards for purity set up by the United States Pharmacopeia for ether of anesthetic quality. Our interest was aroused in this matter by the fact that the considerable difference in cost implies essential differences in the quality of the two kinds of ether, and we undertook to look into it further.

The latest edition of the United States Pharmacopeia (U S P X) makes the following statement in italics in the article on ether: "Caution—Ether to be used for anesthesia must be preserved only in small, well-closed containers, and is not to be used for this purpose, if the original container has been opened longer than twenty-four hours." The twenty-four hour clause was not present in the older pharmacopeias and appeared for the first time in U S P IX, although even there the statement was not prefaced by the term "caution," nor was it emphasized by italics. This statement alone would be quite sufficient to justify the almost universal practice in hospitals of using only quarter-pound or half-pound cans for anesthesia. What remains in the can is usually regarded as unfit for anesthesia on the following day and is used for cleansing or other purposes.

Widely divergent opinions prevail as to the effect on patients of ether taken from a container that has been opened any length of time. Some state that it becomes very irritant, some that it becomes very toxic, so that extremely small quantities produce collapse symptoms, others state that they have found it loses some of its anesthetic properties, so that it becomes almost impossible to induce satisfactory anesthesia. One cannot be impressed with the soundness of these opinions, especially when one bears in mind that impurities have on the one hand been charged with most of the disagreeable effects of ether¹ and on the other hand some of them have been held chiefly responsible for the desirable anesthetic properties of ether.² There is, indeed, a question whether the prevailing views regarding the dangers of ether in a container that has been opened for some time are not notions arising chiefly from the numerous reports in the literature on untoward reactions arising during anesthesia with samples of ether which in some cases proved subsequently to have been impure or to have deteriorated. As a matter of fact, adherence to the practice directed by the U S Pharmacopeia has been so general that one does not readily

find an anesthetist who has had sufficient experience with controlled observations to afford a sound judgment regarding the use of U S P ether for anesthesia taken from metal containers of varying sizes after they have been opened several days.

The fact is well established that, when ether is exposed to air, moisture, light or certain chemical substances which may act as catalysts, it undergoes oxidation with the formation chiefly of toxic aldehydes and peroxides. This oxidation appears to be erratic and to depend on factors that are not always in evidence. For example, Nitardy and Tapley³ stated that the formation of peroxides varies widely in different samples of the same lot of ether, stored in what may appear to be the same kind of containers, and suggested that impurities such as dust or soldering flux may be responsible for some of the differences. Small quantities of peroxides⁴ as well as of aldehydes⁵ are said to accelerate the formation of oxidation products, so that an impure ether would tend to oxidize more quickly. The most important question from the practical standpoint is that regarding the rapidity of these changes under the ordinary conditions in which U S P ether is supplied at the present time. The answer to this question in the literature is not satisfactory, although the prevailing impressions are that they occur very rapidly.

Baskerville⁶ made some of the early and very notable contributions to the chemistry of the oxidation of ether. In one of his papers^{6a} he states "In view of the fact that the presence of the products of the oxidation of ether in excessive amounts gives rise to respiratory irritation during anesthesia, it cannot be too strongly urged that the ether be supplied in small containers, of such a size that they need not be opened without being emptied by use [sic], and any remnants in these containers should not be used for anesthetic or analytical purposes without being subjected to purification." Part of this statement was practically paraphrased in the U S Pharmacopeia IX, which appeared a few years later. The reason for this statement is not evident since Baskerville's own experiments^{6b} gave no indication whatever that oxidation is rapid. He found that aldehydes, peroxides and acids formed in ether in experiments carried out under extreme conditions, namely, colorless bottles, poorly stoppered tin cans, exposure to sunlight and heat and storage for periods in most instances of from 193 to 200 days. In one group of nine specimens of ether in tin containers, he found the test for peroxides negative in the five which were properly stoppered, even though the period of storage was 200 days, those not tightly stoppered giving a positive test. In his conclusions he went further beyond the bounds of his results and stated "Finally, there is no doubt but that the chemical and physical tests even improved ones, are insufficient. They may be stated ever so clearly in print and properly serve to eliminate some low grade material, yet clinical experience must have the final word." The intent of this statement which has been quoted in substance on the labels of ether cans, is not clear unless it is to indicate that a specimen of ether may still be

unsatisfactory for anesthesia even though it fulfils all the chemical and physical requirements of U S P ether. There is no evidence in the literature that lends any support to such a possibility.

More recently, Laws⁷ stated that, since in the closed method of administration (Shipway) oxygen or air is bubbled through ether in a bottle impurities are formed in the apparatus during its administration. He therefore urged that the surplus left after the previous operation be discarded to avoid accumulation of impurities. He did not present any proof that such rapid oxidation of anesthetic ether occurs under ordinary conditions. The literature on the speed of deterioration of ether abounds in statements of a similar nature but they are conspicuous by the dearth of evidence to substantiate them.

The present study was undertaken to ascertain the rapidity of deterioration of U S P ether under ordinary conditions after the metal containers in which it is commonly marketed in the United States at the present time have been opened.

METHOD

A series of specimens of U S P ether were collected. In order to obtain samples that were kept under ordinary conditions but as varied as possible, these specimens were gathered from nine different hospitals and ten different laboratories in New York City. The sources of these specimens, according to the labels, were five different and well known manufacturers or distributors. The metal caps had been cut away from every one of the tin cans which were then stoppered with a cork, except in the case of the steel drums, which were always closed with the special metal cap with which they are provided. With few exceptions the cans of ether were used in animal laboratories, they had been opened from time to time and then set aside to be used again for anesthesia. No special precautions were taken against exposure to air or moisture other than stoppering after the required quantity was used. An approximate estimate was made in each case of the number of times a container was opened. This varied from one to more than ten times (in the case of the 5-pound cans) before the tests were made. In many instances the exact date when the can was opened for the first time was known, in other cases only the approximate interval between the date of the first opening and the date of testing was determined and this was stated in weeks or months. The containers were from one-fifth to three-fourths full at the time of testing for deterioration.

In all there were fifty-three specimens in metal containers, labeled either "U S P Ether" or "Ether for Anesthesia." Of the latter, there were twenty-five specimens. Eight additional specimens of ether stored for varying periods of time in various types of containers other than metal cans were also tested for impurities. The size of the containers and the number of each were as follows: 27-pound and 55-pound drums, three of each, fifteen 5-pound tins, twenty-two 1-pound tins, two half-pound tins, and eight quarter-pound tins. From each container a sample was taken and examined by the U S P tests for aldehydes, peroxides and acids, namely, the cadmium and potassium iodide test for peroxides, the potassium hydroxide test solution for aldehydes and the litmus test for acids. These are the essential impurities that form when anesthetic ether undergoes oxidation on exposure to moisture, air or light during storage.^{8b} There are more

delicate tests both for aldehydes and peroxides⁸ in ether than those described in the Pharmacopeia. Eight specimens were tested for aldehydes by the solid potassium hydroxide test as well, which is stated to be sensitive to about 0.01 per cent of aldehydes, about five times as sensitive as the U S P test with solution of potassium hydroxide.^{8b} It was deemed undesirable to depart from the pharmacopoeial tests, as it would not be possible to interpret the results if one tried to detect deterioration with tests more delicate than those used in many cases when the ether was first introduced into the container.

RESULTS

The results of the tests for aldehydes, peroxides and acids were negative in all of fifty specimens of U S P ether in metal containers that had been opened and again stoppered one or many times at intervals during periods of from four days to eight months from the time the container was first opened to the time a sample was tested for deterioration. The distribution of the specimens according to these periods was as follows: twelve specimens of from four days to one week, eight specimens of from eight days to two weeks, seventeen specimens of from two and a half to four weeks, seven specimens of from five to eight weeks, six specimens of from ten weeks to eight months. Positive tests were obtained on specimens in three metal containers of U S P ether, specimen 51, a 1-pound tin, gave a positive test for peroxides a month after the can had been opened but the can had been very poorly stoppered, specimen 52, a 1-pound tin, gave positive tests for peroxides and aldehydes twelve months after the container was first opened. We were afforded an opportunity to examine another interesting old specimen of ether, which was in a half-pound, rusty, tin can (manufacturer D) and was labeled "ether for anesthesia." The can was nearly full, the metal cap having been cut away and the can tightly stoppered with cork about fifteen years previously. This specimen also gave negative U S P tests for aldehydes and peroxides but a positive one for acid. It has been stated that after prolonged storage aldehydes and peroxides may form and then again disappear,⁹ the end-product in the oxidation being an organic acid.^{8b} The heterogeneous group of specimens of ether, specimens 53 to 60, with one exception (55, ether in a dark brown glass bottle), gave positive tests for peroxides, aldehydes or acids. These however, were either U S P ether exposed to sunlight in colorless bottles or very old specimens, or specimens labeled "not U S P" or "not for medicinal use." The results are presented in somewhat greater detail in a table which is included in the reprints of this article. The terms and numbers which identify the specimens are those used in the table.

In a study of the literature in connection with this problem we have sought to ascertain evidence which would justify the statement in the Pharmacopeia that ether should not be used for anesthesia twenty-four hours after the container has been opened and which would explain the widespread belief that ether in a metal container rapidly deteriorates, so that it becomes unfit for anesthesia shortly after the container has been opened. The literature on the impurities in ether, the oxidation of ether, and methods for the purification, preservation and storage of the drug is very extensive and it would not be feasible to review it here. We have

Soc.* **49**: 2655 (Oct.) 1927. (c) Middleton G. The Preservation of Anesthetic Ether. *Pharm. J.* **59**: 130 (July 26) 1924.

been unable to find, however, strange as it may seem, a single study which shows that U S P ether in the metal containers in which it is at the present time supplied by the better known manufacturers in this country deteriorates rapidly under ordinary conditions after the container has been opened. In some of the papers oxidation products found in specimens of ether are charged to deterioration during storage, without proof that the impurities were not present at the start. Rowe⁹ examined a hundred specimens of anesthetic ether from various sources and found that about one third of them were contaminated chiefly with aldehydes and peroxides and failed to comply with the standards of the U S Pharmacopeia. He suggested that use of the metal containers with appreciable air space in the way in which ether is marketed in this country is partially responsible for the formation of the impurities. There are no details in this paper as to the age of the specimens or as to the manner in which they were stored before the tests for deterioration were made.

The use of suitable means for storing anesthetic ether so as to prevent oxidation has been a problem of considerable importance. In this country, ether is usually stored in metal containers. Nitardy and Tapley³ stated that in practically all samples of pure ether stored in ordinary tin containers peroxides can at one time or another be demonstrated. They found that storage in copper prevents the formation of peroxides, a practice that has been adopted by one of the manufacturers. This appears to have been confirmed in a study from the same laboratories by Deripe, Green and Schoetzow.¹⁰ They divided a lot of anesthetic ether into three types of containers, namely, copper-lined tin cans, ordinary tin cans and glass-stoppered amber bottles, about 170 specimens of 4 ounces in each type. These were stored under identical conditions. They stated that the ether in the copper-lined cans remained free from aldehydes and peroxides for fifteen months, while nine of ten specimens in ordinary tin cans showed peroxides in one month by U S P tests. As this sample deteriorated before the cans were opened and as the first test for deterioration was made after one month, this paper does not throw any light on the reason for the belief that opening of the containers will lead to deterioration in hours or a few days.

U S P ether contains some substances other than ether, namely, water, alcohol, and sometimes traces of other volatile and nonvolatile matter. Some manufacturers claim special purity for their anesthetic ether. They maintain that their ether for anesthesia contains even less of the foregoing impurities than is permitted by the Pharmacopeia in anesthetic ether. Such statements usually appeal to the popular imagination. The purification of drugs to a degree that is unnecessary for practical therapeutics cannot be considered justified if the process entails a marked increase in their cost. A notable example is the case of the digitalis bodies, from which some manufacturers remove impurities that do not interfere with the efficiency of the drug resulting in extremely costly preparations. There is no satisfactory clinical or experimental evidence that specially purified ether has any material advantage for anesthesia in man over that which meets the U S P requirements for anesthetic ether.

The subject of the effects of ether that has undergone deterioration does not come strictly within the

scope of this paper. It may be well to state, however, that in our study of the literature it has been difficult to escape the conviction that the dangers of small amounts of peroxides and aldehydes have been grossly overrated.¹¹ Various toxic symptoms occurring during ether anesthesia have been attributed to impurities in ether,¹² although these have also been observed with pure ether.¹³ Some authors have stressed improper technique in its administration as the chief cause of the disagreeable or toxic complications.¹⁴ A paper by Mita¹⁵ has been quoted as showing the toxic effects of oxidized ether locally and on the heart and central nervous system. His experiments were carried out on frogs, in which toxic effects were induced by the injection of extracts of deteriorated ether in quantities equivalent to about 5 to 10 liters of ether for man, and the age of these preparations was not stated. Bourne¹⁶ found that while the addition of 0.5 per cent peroxides or 1.0 per cent acetaldehyde to ether administered to dogs caused respiratory and circulatory disturbances, 0.3 per cent peroxides or 0.5 per cent acetaldehyde had no appreciable effect.

Since the U S P tests detect both substances in much greater dilution these results offer no justification for some of the special therapeutic claims that are made for ether purified beyond the pharmacopeial requirements. Mendenhall and Connolly¹⁷ performed similar experiments and found that ether contaminated with from 0.1 to 1.0 per cent aldehydes or peroxides produced no perceptible effects on the heart, blood pressure or respiration in normal cats. They found, however, that ether contaminated with small quantities of peroxides and aldehydes depressed the movement of cilia of the oyster and suggested that such an action may be responsible for the cases of pneumonia, which they believed resulted from the use of impure ether in their hospital. In this connection it is to be noted that some authors have recently recommended acetaldehyde by mouth and by injection as an effective measure against circulatory depression in alimentary toxemias and in various severe infections, including pneumonia.¹⁸

It is necessary to stress the fact that we do not propose that ether containing appreciable quantities of oxidation products is desirable for anesthesia. The opinions are widely held that minute quantities of aldehydes and peroxides in ether are injurious¹ and that anesthetic ether becomes unfit for anesthesia within twenty-four hours after the container has been opened. These views have played an important role in the development of certain practices, such as (1) demands for special purification of ether for anesthesia suggesting that official U S P ether is not adequate for that purpose, (2) the use of ether for anesthesia only in small containers, and (3) condemning for anesthetic purposes the remainder in the can opened a day or so

previously. One of the results has been an inordinate increase in the cost of anesthetic ether. For example, in one hospital the sum of \$383 was spent for anesthetic ether in quarter-pound and half-pound cans in one year. All this could have been satisfactorily supplied for about \$70 if U S P ether had been bought in 27-pound or 55-pound drums. Small tin containers could be filled daily from these drums, they could be stoppered with ordinary cork and supplied to the operating rooms by the hospital pharmacist. In the average hospital, one or more of these drums would be consumed in about one or two weeks. One may readily imagine the extent of the saving if this procedure should be generally adopted throughout the United States.

The matter of cost is only secondary to be sure, and no amount of saving would justify the use of ether that contains impurities causing toxic effects. There is, however, no evidence in the literature to justify the anxiety over the traces of impurities that may be found in ether complying with the U S P requirements for anesthetic ether, or over the supposed rapid deterioration of ether in metal containers that have been opened part of the contents used and the remainder stoppered with cork. The present study of more than fifty specimens shows that U S P ether does not deteriorate rapidly. As we have shown, after the containers had been opened and again stoppered many times during periods of from several days to several months, the ether still gave negative tests for aldehydes, peroxides and acids, the oxidation products which are held chiefly responsible for the toxic effects of deteriorated ether. These results were obtained with ether from five different manufacturers or distributors, supplied in containers varying from quarter-pound cans to 55-pound drums. In many cases the labels stated that the cans were copper lined, or so treated as to become "catalytically inert," or to contain a coil of steel wire to inhibit oxidation. In the case of the steel drums, as well as many of the tin cans, no special claims regarding the quality of the containers were made. The results were identical in all.

CONCLUSIONS

1 U S P ether in metal cans as it is supplied in this country at the present time by the better known manufacturers, does not deteriorate rapidly under ordinary conditions when the metal containers are opened. The present study shows that the can may be opened and again stoppered with cork many times during periods of weeks without oxidation detectable by the U S P tests.

2 There is no evidence that ether specially purified "for anesthesia" has any material advantage over ordinary U S P ether for anesthetic purposes.

3 It is recommended that hospitals buy ordinary U S P ether in large steel drums and that for anesthesia the operating room be supplied with ether in small tin cans filled daily from the drums by the hospital pharmacist. The ether in the drum may be tested daily for aldehydes and peroxides, there being very simple tests for each requiring only from five to ten minutes to perform. This would help not only to correct an erroneous view regarding the speed of deterioration of ether after the container is opened but to abolish the extravagant practice of buying ether in hundreds of quarter-pound or half-pound cans at from four to six times the cost of ether in drums, when large quantities of ether for anesthesia are used.

PNEUMOCOCCIC MENINGITIS

REPORT OF CASE WITH RECOVERY FOLLOWING CISTERNAL DRAINAGE

CAROLINE C. BEDELL, M.D.
BALTIMORE

Pneumococcic meningitis is almost inevitably a fatal disease. Scattered reports of recovery have appeared in the medical literature, the reader is referred to papers by Harkavy,¹ Globus and Kasanin,² and Stoessiger³ for critical reviews of such cases. As yet there is no therapeutic procedure that is widely accepted in the specific treatment of pneumococcic meningitis. It is therefore desirable to report a case in which complete recovery followed the early use of continuous cisternal drainage, in the hope of stimulating further trial of this method, described by Dandy⁴ in the treatment of staphylococcic and streptococcic meningitis.

REPORT OF CASE

History.—A Negro woman aged 42, who came to the Johns Hopkins Hospital June 7, 1932, complained of severe right-sided headache. In general her health had been good. Fifteen months before she had suffered from weakness, her local physician discovered sugar in the urine for which he prescribed a low carbohydrate diet. In September 1931, she was first seen in the outpatient dispensary on account of intermittent parietal headache radiating to the left frontal region. Physical examination was essentially normal and the urine was sugar free but the blood sugar showed a typical diabetic curve following ingestion of dextrose, and the blood Wassermann reaction was positive. Although there were no signs nor history of syphilis, the patient's husband who was in the medical ward had syphilitic aortitis and aortic insufficiency. Her spinal fluid in December, 1931, showed 4 cells with the Wassermann, mastic curve and globulin tests negative. Roentgenograms of the skull on two occasions were negative. From September to May she received weekly injections of arsphenamine or a bis muth compound; the headache was relieved after the first injection. The diabetes was readily controlled on a diet of 60 Gm of protein, 140 Gm of fat and 80 Gm of carbohydrate.

June 4 she was seized with a constant severe, right-sided headache, which radiated from the vertex to the right frontal region and behind the right eye. She had not had a recent cold but had had occasional postnasal discharge. The headache persisted and on June 7 she was examined in the outpatient dispensary where it was noted that she was in acute pain and seemed rather dazed and that there was marked tenderness on light percussion above the right eyebrow, extending up to the top of the head. The right antrum was dark on transillumination with a moderate amount of discharge coming from the meatus, the other sinuses seemed clear. The antrum was punctured and irrigated with boric acid, and a small amount of mucoid material was obtained but no frank pus. Some difficulty was encountered during the irrigation, and on this account she was admitted to the ward in the otolaryngologic service for observation.

On admission, her temperature was normal, but the following afternoon June 8, it rose to 102.4 F, the headache was more severe and she complained of some pain on the right side of the neck. June 9, the right upper eyelid became edematous and partially closed, with pain in the right frontal region and considerable postnasal discharge. The temperature continued to mount, reaching 105.4 F on June 10, at which time she became

semistuporous, with a stiff neck and a positive Kernig sign. Lumbar puncture showed purulent fluid under increased pressure and she was transferred to the medical service with the diagnosis of meningitis.

Examination—The temperature was 106, the pulse 94, the respiration rate 20 and the blood pressure 130 systolic, 70 diastolic.

The patient was well developed and appeared acutely ill, drowsy and delirious at times but responded to simple questions and cooperated to some extent during the examination. She still complained of right frontal headache. The upper lid was so swollen that it could barely be opened. The ear drums appeared normal. There was marked oral sepsis with many gold crowned teeth, in one of which a diamond was set. Interest centered in the neurologic examination, the neck was definitely stiff but not retracted. Ophthalmoscopic examination showed fullness of the veins and hyperemia of both optic disks without elevation or blurring of the disk margins. Otherwise the cranial nerves were intact, and no sensory or motor disturbance was noted. The deep reflexes were increased in the upper extremities while the knee jerks and ankle jerks were normal. Abdominal reflexes were absent, and there was a suggestively positive Babinski sign on the left. There was no patellar nor ankle clonus. Kernig's sign was present but not marked and was more definite on the left than on the right.

The blood Wassermann reaction was positive.

The blood count showed red blood cells 4,600,000, hemoglobin 80 per cent, white blood cells 20,500, polymorphonuclears, 88 per cent.

The urine was acid with a specific gravity of 1.017. Sugar was not present, albumin +, and acetone +. A few white blood cells were found in the sediment but no red blood cells or casts.

The blood chemistry showed fasting sugar 140 mg per hundred cubic centimeters, nonprotein nitrogen 26 mg per hundred cubic centimeters. Culture of the urine yielded a heavy growth of *Bacillus coli*.

A roentgenogram of the chest showed that the lungs were clear. One of the sinuses showed an old infection of both antrums, the frontals and ethmoids were cloudy.

The blood culture was sterile.

Lumbar puncture revealed diffusely cloudy cerebrospinal fluid without flakes. Twenty-five cubic centimeters of fluid was withdrawn under an initial pressure of 350 mm of water. The Queckenstedt sign was negative. The cell count was 8,000 white blood cells with 88 per cent polymorphonuclears. Smear stained by Gram's method showed many gram positive diplococci. The spinal fluid yielded a pure culture of pneumococcus group IV.

Treatment—In view of the relatively early stage of the meningitis and the good condition of the patient, this was considered an excellent case in which to try a radical measure of cerebrospinal drainage. After various methods of therapy advocated in recent literature had been considered, the following plan of treatment was decided on:

- 1 Continuous cisternal drainage
- 2 Frequent lumbar puncture
- 3 Cisternolumbar irrigations
- 4 Cisternal irrigations
- 5 Periodic cerebral dehydration with hypertonic dextrose

On the day on which symptoms of meningitis appeared, a rubber drainage tube was introduced into the cisterna magna. The operation was performed under general anesthesia by Dr. Frederick Geib. At that time her temperature was 106, pulse 94 and respiration rate 20. She received 75 mg of tribromethanol per kilogram rectally and 4 ounces (120 cc) of ether. Posterior trephine openings were made in case it should be desirable to tap the lateral ventricles but this was never done. A midline incision was made over the lower part of the occiput and the muscles were divided. An opening about 2 cm in diameter was resected in the occiput the lower margin of which was close to the atlas. When the dura was opened in the midline thickened leptomeninges and a thin layer of exudate were found. One hundred cubic centimeters of fluid under pressure was aspirated from the cisterna magna. A number 14 soft rubber catheter was used as a drainage tube,

but a larger one would probably have been preferable. After the hole and tip of the catheter had been cut off, two opposing U-shaped pieces were cut out of this end. One centimeter above the U-shaped openings, two holes were cut in the opposite plane. This end of the catheter was now sutured with interrupted black silk flush to the dura on each side, near the lower margin of the bony defect. Above and below the tube, the dura was left wide open. The muscles were closed and the tube was anchored to the skin by two silk sutures. This closure provided free drainage through the dura into a space about the end of the catheter, which in turn was drained by the many holes in the tube. The successful drainage seemed to be due in large part to this procedure.

The drainage system was so built that it would allow us to vary the pressure in the system. A thin neck gallon bottle was fitted with a two hole rubber stopper, and the short arm of a right angle piece of glass tubing was placed through one of the holes. About 3 feet of one-fourth inch rubber tubing and glass connections, one of which was a double circle to act as a trap, was used to connect the catheter to the bottle. The system was sterilized and connected to the drainage tube and the second hole in the rubber stopper plugged with sterile cotton. Thus the inside of the bottle remained at atmospheric pressure. Positive or negative pressure could be exerted on the fluid in the system by raising and lowering the bottle. Negative pressure was avoided in order to keep the brain stem from being sucked against the dura closing off the drainage openings. Maximum flow was obtained when the top of the glass angle tube was elevated several centimeters above the cisterna level. The exact conditions for obtaining optimum flow had to be frequently redetermined by slightly raising or lowering the bottle. Approximately 200 cc of cerebrospinal fluid was drained from the cisterna magna every twenty-four hours by this method.

With the patient in the lateral decubitus lumbar puncture was performed every twenty-four hours from June 10 to June 23. During the period of continuous cisternal drainage the spinal fluid was not under pressure and little fluid was obtained from the lumbar needle. After the cisterna was closed, from 30 to 40 cc of fluid was removed daily by this process.

With the lumbar needle in place 50 cc of warm physiologic solution of sodium chloride was slowly introduced by gravity into the cisternal catheter (temporarily disconnected from the drainage bottle) and allowed to escape by the lumbar route. Although there was considerable variability in the cell count of the fluid obtained the cell count at the end of the procedure was usually much lower than the initial one.

As soon as the irrigation just described was completed, the lumbar needle was withdrawn. Small amounts of physiologic solution of sodium chloride were then gently introduced into the cisterna and removed by the same route in order to wash out flakes of exudate from the cisternal region as thoroughly as possible. During both forms of irrigation the patient showed increasing motor excitability, but serious respiratory or circulatory disturbance was never noted.

It is well known that the volume of the brain can be reduced by intravenous injection of hypertonic solutions. By using this principle, we hoped to facilitate subarachnoid drainage and prevent blockage of the basal cisternae. After fluids had been withheld for an hour, 100 cc of 50 per cent dextrose was given intravenously daily, as shown in the chart. Two hours later, fluids were forced. No conspicuous change in the rate of flow of cerebrospinal fluid was noted during this period. Although it is difficult to estimate the value of this procedure, it certainly deserves further trial.

The patient was turned daily from side to side, care was taken to prevent her lying on her back or raising her head. For ten days restlessness was controlled by paraldehyde, from 10 to 20 cc by rectum. Morphine in doses of from 12 to 16 mg and restraint of the hands and feet as indicated. A liquid diet was given by mouth and fluids were supplemented by rectal dextrose and saline infusions in order to bring the total fluid intake up to from 3,000 to 4,000 cc a day. A transfusion of 500 cc of citrated blood was given, June 20.

Course—Following the operative insertion of the drainage tube in the cisterna magna the temperature fell from 106 to 102 and never rose above 104 thereafter. Simultaneously, the

pulse rate rose from 94 to 120 and as long as free cisternal drainage persisted no further relative bradycardia was noted. For ten days, improvement in the general condition was slight. The patient cooperated to the extent of taking nourishment by mouth but remained delirious and incontinent of urine. There was no vomiting. The neurologic status was essentially unchanged, papilledema did not increase, and no localizing signs appeared.

The important features of her course are shown in the chart. Gram-positive diplococci were seen daily in the smears of the spinal fluid sediment until June 17. After the saline irrigations were started, growth of pneumococci was no longer obtained. Four days after the insertion of the tube the cerebrospinal fluid was almost clear, but in the next few days it became rapidly more purulent with thick flakes of exudate escaping through the tubing. *Bacillus proteus* now grew abundantly from the spinal fluid. June 18 the catheter became plugged with fibrin and the pulse rate dropped to 68. On the same day the cisternal catheter was removed, the wound appeared clean and was dressed with gauze, without being closed in any way. Two lumbar punctures were done, June 18, to relieve pressure, thereafter they were performed daily. The spinal fluid rapidly cleared, June 23 there were 240 cells with 70 per cent polymorphonuclears, and culture yielded *Bacillus proteus* for the last time. From June 20 there was steady clinical improvement, the patient was discharged from the ward July 28 without residual signs of any sort. Lumbar puncture July 21

The objection has been raised to many of the reported cases of recovery in pneumococcic meningitis that the organism was not properly identified. We were fully aware of the importance of careful bacteriologic studies. Repeated determinations were made of the typing, the bile solubility and the autolysis in salt solution of the organism isolated. There seemed to be no question that we were dealing with a pure culture of pneumococcus group IV.

Pneumococci, while plentiful, were never found in overwhelming numbers in the spinal fluid. This suggests that early establishment of drainage and irrigation was effective in combating their rapid multiplication. It is, of course, impossible to say that the patient would not have recovered without surgical intervention. It seems unlikely, however, that the rapid progression of symptoms and abrupt rise of temperature to 106 during the hours of meningeal invasion would have spontaneously ceased, as occurred immediately after the operation.

Dandy⁴ indicates that the origin of the meningitis has definite bearing on the prognosis. He suggests that meningitis of otogenous origin is probably more grave than that following trauma or accidental inoculation of the cerebrospinal fluid. The present case may be allied to the latter group. There was a preceding sinusitis, which was never severe, in addition, the antrum wall was traumatized during irrigation. The sinusitis subsided spontaneously during hospitalization so that there was no focus continually feeding the meninges.

The secondary infection of the meninges with *Bacillus proteus*, an organism of low pathogenicity, is of considerable importance. The patient actually suffered from two attacks of acute meningitis occurring in quick succession. The cisternal drainage tube had been in place six days when the superinfection occurred, gram-positive cocci were still present in the smear of the spinal fluid sediment, chiefly intracellularly. Culture of the spinal fluid over a period of nine days yielded *Bacillus proteus*, thereafter the cultures were sterile. The *Bacillus proteus* infection produced a greater polymorphonuclear response in both blood and spinal fluid than had the pneumococcic infection alone, whether this outpouring of leukocytes could have been helpful in clearing up the residual pneumococcic infection is an interesting question. The exact mode of entry of the secondary invader could not be determined, but the occurrence is hardly surprising, since the catheter had been in place six days and had been subject to repeated manipulations, while the dressings about the open cervical wound had not been changed for fear of disturbing the functional efficiency of the drainage tube.

SUMMARY

In a case of pneumococcic meningitis, group IV, a drainage tube was inserted into the cisterna magna as soon as signs of meningeal invasion were observed. The tube remained in place for eight days, 200 cc of cerebrospinal fluid escaped daily by this route. Irrigations with physiologic solution of sodium chloride were carried out from the cisterna magna to the lumbar region. Periodic shrinkage of the brain volume was attempted by intravenous injections of hypertonic dextrose. The spinal fluid became secondarily infected with *Bacillus proteus* at the end of six days, producing a marked leukocytic response. There was progressive improvement, however, and the patient left the hospital completely recovered at the end of seven weeks.

The temperature, white blood cell count, cerebrospinal fluid cell count and cultures during the period of treatment. The temperature is shown during the invasion of the meninges from June 7 to June 10. The unblocked columns from June 11 to June 14 indicate the appearance of gram-positive diplococci in smears of the spinal fluid although cultures were sterile.

showed normal pressure, a negative Queckenstedt sign, 40 cells with 39 lymphocytes and 1 polymorphonuclear, and a negative culture and Wassermann reaction. A year later, June 20, 1933, neurologic examination was negative, lumbar puncture showed 7 mononuclear cells and normal pressure. Culture was negative.

COMMENT

It is probable that only early cases of pneumococcic meningitis would respond favorably to such a course of treatment, since it depends on free flow of cerebrospinal fluid from the ventriculosubarachnoid system. In such a fulminating disease it is only a matter of hours before the thickness of the meningeal exudate and the formation of adhesions would make this method of doubtful value. It is significant that 200 cc of cerebrospinal fluid escaped from the cisternal tube daily, far exceeding the amount usually obtained in cases of purulent meningitis drained by repeated lumbar punctures alone. The maintenance of approximately normal intracranial pressure throughout the course of the disease is desirable from the standpoint of minimizing intracranial lesions and for the general welfare of the patient.

SPLENECTOMY IN CHRONIC ARTHRITIS

ASSOCIATED WITH SPLENO-MEGALY AND LEUKO-
PENIA (FELTY'S SYNDROME)ERLE B CRAVEN, JR, MD
DURHAM, N C

Hanrahan and Miller¹ have recently called attention to an association of chronic arthritis, splenomegaly and leukopenia, first reported by Felty² in 1924. In the voluminous literature dealing with chronic arthritis, splenomegaly and leukopenia as separate entities, the simultaneous occurrence of the three abnormalities is not mentioned except in these two papers.

There was marked improvement following splenectomy in both the arthritic and the leukopenic features of the case reported by Hanrahan and Miller.¹ The present report is offered with additional observations on a similar case and with a description of the apparently transient effect of splenectomy.

REPORT OF CASE

L S, a white woman, aged 40 admitted to the medical service, Sept 20, 1932, complained of pain in the joints of four years' duration.

Except for a brother who suffers from arthritis, the details of which are unknown, the family history was irrelevant. There was nothing in the past history which was considered important.

The present illness began in November, 1927, with pain and stiffness in the lower part of the back beginning nine days after the spontaneous termination of a normal pregnancy. Three weeks later the left wrist and left ankle became swollen, hot, tender, and painful on motion. The swelling and most of the tenderness subsided after two or three days, but at intervals of two or three weeks throughout the next two years there were short periods of arthralgia associated with stiffness of the joints but without obvious deformity.

Two years after the onset there was a second acute phase, lasting about a week, during which there was simultaneous involvement of both shoulders, the right ankle, the right elbow and the right wrist.

Six months before admission the left knee became swollen, hot and tender and after the acute phase had passed the knee was stiff and was painful on motion. One month before admission the right knee was similarly affected, and two weeks before entry the right ankle became acutely swollen for the second time.

During the first three years of her illness there was no permanent disability following cessation of the attacks of acute inflammation, but as a result of the attacks of the past six months the patient has been obliged to use crutches.

The patient had lost from 40 to 50 pounds (from 18 to 22.7 kg) during the course of her illness.

A curious fact, voluntarily contributed by the patient was that during the menses the joint pains were markedly diminished.

The patient was poorly nourished and had a peculiar yellowish brown, blotchy pigmentation of the skin over the neck, face, forearms and tibiae. The tip of the nose was diffusely red and many dilated capillaries were visible. The epitrochlear and inguinal lymph nodes were moderately enlarged but not tender. There was dense scarring of the right cornea and internal strabismus with enophthalmos due to an old injury. The teeth were dirty and carious and the gums infected and recesive. The heart and lungs were normal. The thin smooth edge of the liver was felt 7 cm below the costal margin in the right midclavicular line. The large and hard spleen extended 4 cm below the costal margin. The edge was smooth, the median notch was not felt.

There was moderate tenderness and pain on motion of the metatarsophalangeal joints and both ankle joints but no local swelling, heat or limitation of motion. Slight pain on motion occurred in both hip joints. There was swelling, slightly increased local heat and moderate pain and limitation of motion but no redness, in the left knee. There was slight pain on motion in the right knee, but no swelling or local heat. The heads of the second and third metacarpals of both hands were enlarged and tender on motion. Subluxation of the left second metacarpophalangeal joint was observed. Both wrists were moderately tender and painful on motion, with definite limitation of motion on the right. There was marked atrophy of the interossei. Both shoulders were slightly tender and painful on motion, and abduction of both arms was moderately limited. No tenderness or limitation of motion of the vertebral column was noted. The temporomandibular and sternoclavicular joints were normal.

Examination of the blood showed red blood cells, 3,000,000, hemoglobin, 11 Gm per hundred cubic centimeters (Sahli), mean hemoglobin content, 36×10^{-12} Gm, white blood cells,

2,500, differential count polymorphonuclear neutrophils, 52 per cent, polymorphonuclear eosinophils, 12 per cent, small lymphocytes, 32 per cent, monocytes, 4 per cent, reticulocytes, 3 per cent. The stained smear showed mild anisocytosis but no poikilocytes, macrocytes or parasites. Stool examination showed no abnormalities, and cultures for B hemolytic streptococci were negative. The urine showed urobilinogen to be present in a dilution of 1 to 3. No bilirubin was present. Blood chemistry showed van den Bergh reaction, negative, calcium 9.0 mg per hundred cubic centimeters phosphorus, 4.2 mg refractive index, 1.3493. A sugar tolerance test gave the following results: fasting 110 mg per hundred cubic centimeters, one-half hour, 210 mg per hundred cubic centimeters, one hour 263 mg, one and one-half hours 190 mg, and two hours, 115 mg. A repetition of the test gave exactly comparable results. A bromsulphalein test of the liver function showed a 45 per cent retention of the dye after thirty minutes and a 30 per cent retention after one hour. Roentgenograms of the accessory nasal sinuses showed slight haziness over both antrums, interpreted as thickened mucous membranes. The other sinuses were clear. There was moderate alveolar absorption about the

2. Felty, A. R.: Chronic Arthritis in the Adult Associated with Splenomegaly and Leukopenia. *Bull. Johns Hopkins Hosp.* 35: 16 (Jan) 1924.

teeth but there were no apical abscesses. Roentgenograms of the right hand, wrist and knee showed a moderate grade of atrophic arthritis. The carpal bones were deformed about their margins, and the joint spaces, excepting the knee joint, were partially obliterated. Gastric analysis of the fasting contents showed free hydrochloric acid 4, total 20, after alcohol and ergamine, free hydrochloric acid 76, total 96. The Wassermann reaction of the blood was negative. A blood culture was negative.

There was an irregular fever ranging between 37 and 38 C (98.6 and 100.4 F), reaching in one instance 38.8 C (101.8 F), during the first three weeks in the hospital. The white blood cells ranged between 2,500 and 3,700 per cubic millimeter, as shown in the table. There was severe joint pain, particularly in the left hand and left knee which required frequent doses of amidopyrine and codeine for relief.

The patient was discharged, October 8 and readmitted, October 22. She had shown no improvement during the interval. A blood count revealed red blood cells 3,900,000, hemoglobin, 10.9 Gm per hundred cubic centimeters (Sahli), mean hemoglobin content 25×10^{-1} Gm, white blood cells 5,800, differential count polymorphonuclear neutrophils, 80 per cent, polymorphonuclear eosinophils 3 per cent, polymorphonuclear basophils, 1 per cent, small lymphocytes, 7 per cent, large lymphocytes 1 per cent and monocytes 8 per cent. The next day the white count had fallen to 3,500 and did not rise above 3,700 until October 27, when, following a transfusion of 400 cc of citrated blood, a count of 4,000 per cubic millimeter was obtained.

Splenectomy was performed October 31 and an epitrochlear lymph node was removed. The firm, dark, purple spleen weighed 620 Gm and measured 18 cm by 11 cm by 5.5 cm. There were a few dense adhesions overlying small scars in the splenic tissue. The cut surface was markedly swollen, but in spite of this the interstitial tissue and malpighian bodies stood out prominently. Microscopic sections showed the sinuses dilated and filled with red blood cells. The pulp was rich in cells, many of which appeared to be of the plasma cell type. Large pale phagocytes, some of which contained one, others two and three, nuclei occurred here and there. Occasionally, these large cells contained phagocytized red cells. A moderate number of adult eosinophils were scattered throughout the pulp. The malpighian bodies were unusually prominent and contained strikingly large germinal centers.

A green streptococcus was obtained from culture of the lymph node. Endermal injection of a formaldehyde treated broth culture showed moderate skin sensitivity.

The postoperative course was uneventful, but the patient continued to have daily fever, up to 38 and 38.6 C (100.4 and 101.5 F). Eight days after operation the white blood cells had reached 8,500 and thereafter until the day of discharge the count ranged between 7,800 and 11,000. There was a striking subjective improvement, the patient complaining of pain only at rare intervals. Objectively, three weeks after operation, there was increased mobility in the knees, shoulders and wrists and less swelling of the left knee. The red blood cells and hemoglobin continued to increase, reaching a level of 5,100,000 and 11.4 Gm per hundred cubic centimeters, respectively, twenty-two days after transfusion and eighteen days after operation. During this period of convalescence the patient received only a well balanced diet without additional iron or other medication.

The patient was discharged improved, December 16, and readmitted for further study, July 7, 1933, approximately eight months after splenectomy. The interval history was as follows. During her first week at home she was confined to bed because of pleuritic pains on the right side but during the following month there was gradual improvement in the condition of the joints, manifested by an increase in mobility and utility and an absence of acute swelling and tenderness. This period of improvement was succeeded by another stage of acute arthritis involving the shoulders and neck and accompanied by a crop of large tender subcutaneous nodules, which appeared about the shoulders and suboccipital region, and across the forehead. The acute swelling and pain subsided after a few weeks and the subcutaneous nodules slowly receded. Variable pain and stiffness remained, however, in the shoulders and

neck up until the time of her last admission to the hospital. Her body weight had increased from 43.8 Kg to 45 Kg.

Except for the complete disappearance of the blotchy yellow pigmentation of the skin noted before splenectomy and a moderate increase in mobility of the hands, elbows, knees and ankles, there was little in the physical examination that differed from the observations at the last examination. The patient was still undernourished, cachectic and irregularly febrile. There was moderate stiffness of the neck and shoulders and considerable pain on passive motion. The residuum of the subcutaneous nodules about the occiput could still be felt, but the nodules around the shoulders and across the forehead were no longer present. A large subcutaneous nodule was present opposite the right olecranon. The liver edge could still be palpated 7 cm below the costal margin.

Roentgenograms of the joints, when compared with previous films, showed little change except for a slightly greater degree of decalcification. The urine contained no urobilinogen and the van den Bergh reaction of the blood was negative. Blood calcium was 8.3 mg and phosphorus 4.9 mg per hundred cubic centimeters. Nonprotein nitrogen was 28 mg per hundred cubic centimeters, cholesterol was 188 mg. The refractive index (plasma) was 1.3499.

A repetition of the bromsulphalein test of the liver function showed 30 per cent retention after five minutes but no retention after half an hour. A galactose tolerance test showed no reducing substances in the urine collected for six hours after the ingestion of 40 Gm of galactose.

The blood studies showed a decided tendency toward a return to the condition that prevailed before splenectomy: a fall in the total white count and in the proportion of polymorphonuclears and a diminution of the total red cell count, shown in the accompanying table.

COMMENT

The essential features of the cases reported by Felty and by Hanrahan and Miller¹ are as follows. The complex of symptoms occurs in individuals of middle age and is associated with pronounced undernutrition, but in contrast to the chronicity of the joint affliction and severe joint pains there is surprisingly little objective evidence of widespread joint destruction or deformity. All of Felty's cases presented a mottled yellowish-brown pigmentation of the skin, confined to the exposed surfaces in four cases but generalized in one. Skin pigmentation is not mentioned as a feature of Hanrahan and Miller's case but occurred in the case reported here and disappeared some months after splenectomy. In three of Felty's cases there was definite enlargement of the axillary, inguinal and epitrochlear lymph nodes. In the present case the epitrochlear and inguinal nodes were moderately enlarged but were not tender. No lymph node enlargement was found in Hanrahan and Miller's case. Felty observed no subcutaneous nodules in his cases, but in the case of Hanrahan and Miller there were tender, red nodules at the bases of both first toes and a large painless nodule under the skin of the left arm near the elbow. Subcutaneous nodules appeared in my case approximately two months after splenectomy.

Splenic enlargement occurred in all cases and was often of considerable extent, in two of Felty's cases reaching to the level of the umbilicus and, in a third, to 5 cm below this level. The spleen removed from Hanrahan and Miller's patient weighed 525 Gm, and that removed in the case reported here weighed 620 Gm.

The microscopic picture as reported by Hanrahan and Miller shows unusually dilated splenic sinuses and thickening of the intersinusoidal spaces. They described many cells of different types, but especially great numbers of what appeared to be large plasma cells. Sections of the spleen removed in my case showed essentially the same picture. The sinuses are dilated

and filled with red blood cells. In the pulp there are great numbers of plasma cells, and, scattered here and there a few large mononuclear phagocytes. Occasionally, the larger cells have double and triple nuclei. In certain areas of sections in my case there were collections of eosinophil polymorphonuclears distributed

Fig 1—Appearance of spleen under low power showing the large malpighian body and the cellular nature of the pulp

irregularly. In both cases, the malpighian bodies are enlarged and contain unusually prominent germinal centers.

The question of liver involvement in the association of diseases under discussion is of considerable importance if an attempt is made to establish Felty's syndrome as a disease entity rather than as the chance simultaneous occurrence of arthritis with splenomegaly and leukopenia. In none of Felty's cases was there enlargement of the liver, but in one case urobilin was found in the urine. The presence of urobilin cannot, however, be interpreted as evidence of liver disease. The liver was moderately enlarged in Hanrahan and Miller's case and a block removed at operation showed fatty changes in the central spaces and moderate round cell infiltration along the portal vein radicles. As they point out, however, the block of tissue was removed from the free edge of the organ, where such changes are not uncommonly found. In the present case there was marked retention of bromsulphalein preceding splenectomy but only an insignificant retention eight months after the spleen had been removed. A galactose tolerance test gave normal results after splenectomy. The urine contained no bilirubin and no more than the normal amount of urobilinogen. The van den Bergh test of the blood was negative. Clinically there was no evidence of liver disease except for the moderate hepatic enlargement and the retention of bromsulphalein.

A mild secondary anemia occurs in all cases; the red cells varying from 3,000,000 to 4,800,000 and the hemoglobin from 70 to 91 per cent. The leukocyte count in Felty's cases varied from 1,000 to 4,200 in four cases being below 3,000. Hanrahan and Miller's patient had only 800 white blood cells per cubic millimeter on admission.

Felty did not consider the differential formula important, but in two of his three cases in which differential counts were reported there was a marked relative as well as an absolute neutropenia. Hanrahan and Miller's case also showed a pronounced relative and absolute neutropenia. The polymorphonuclear percentage of the total white blood cell count in my case was as low as 40 and as high as 80 preceding splenectomy.

A persistent, although variable, eosinophilia was a feature of the present case, the percentage of eosinophils varying from 12 to 1 in different counts and persisting after splenectomy. Hanrahan and Miller's case did not show more than 1 per cent of eosinophils, but in Felty's series two of the three cases in which differential counts were made showed an eosinophilia of 4 and 13 per cent, respectively. Splenomegaly with eosinophilia has been described by Harrison,³ who reported a case of his own and other cases culled from the literature. The clinical features in his reports consisted of splenomegaly and a moderate degree of lymphadenopathy associated with a leukocytosis of varying degree and a very high percentage of adult eosinophils. Harrison considered the cases to represent a distinct syndrome, but Drennan and Biggart⁴ and Hay and Evans⁵ were more impressed by the leukemic features of the disease and considered the eosinophilia merely a symptomatic bone marrow response. For an interesting discussion of the etiology and pathogenesis of the cases, one is referred to the paper of Hay and Evans.

Leukopenia and eosinophilia in chronic arthritis are not uncommon. In a study of the blood cell count in chronic arthritis, Eaton⁶ found a leukopenia in 22 per cent and a neutropenia (under 60 per cent) in 43 per cent of 250 patients. Schilling⁷ reported a case with

Fig 2—Section of spleen under high power showing several large mononuclear and multinuclear phagocytes and plasma cells

51 per cent of neutrophils and 7 per cent of eosinophils. Eaton cites the thirty-three cases of Barrow and Armstrong⁸ with an average of 50 per cent of poly-

morphonuclear leukocytes Kahlmeter⁹ however, in a study of 169 cases of arthritis found a normal range of the leukocytes during the afebrile periods and a mild leukocytosis during fever. Almost 10 per cent of Eaton's cases exhibited an eosinophilia (5 per cent and over), the highest count being 9 per cent. Pemberton¹⁰ mentions an eosinophilia of from 5 to 8 per cent as a feature in several of his severe cases. Barrow and Armstrong⁸ reported no increase of eosinophils.

The occurrence of a lowered sugar tolerance or a delayed sugar removal¹⁰ in chronic arthritis has long been recognized.¹¹ In my case the curve of the blood sugar values, beginning with the fasting level and continuing at half hour intervals after the peroral administration of 100 Gm of dextrose, is similar to that observed in mild diabetes.

Whether the transient improvement in the arthritic features of the disease following splenectomy is due to the increased hemoglobin and red blood cells or to the increased number of leukocytes in the circulating blood or to other factors cannot be settled at the present time. The experience of my patient that the joint pains were always less severe during menstruation is exceedingly interesting but difficult to interpret. Peirce and Pemberton¹² and Crouter and Cajori¹³ have demonstrated the relatively low red cell counts in the peripheral blood in chronic arthritis. Pemberton¹⁰ and others have described the beneficial effect of measures used to improve the peripheral circulation. Presumably during menstruation any tendency toward anemia would be accentuated, and one would expect an exacerbation of symptoms rather than improvement. Since there does not occur an appreciable leukocytosis during menstruation,¹⁴ the improvement in my patient during the catamenia cannot be ascribed to this factor. Probably the increased oxygen capacity and leukocytic factors are jointly responsible.

Because of the paucity of knowledge concerning a causal relationship between the essential features of the small number of cases thus far reported, it is possible only to speculate about a probable common etiologic basis for the simultaneous occurrence of chronic arthritis, splenomegaly and leukopenia. The histologic changes in the spleen cannot be considered a pathologic entity since similar changes are commonly found in a variety of acute and chronic infections.

Splenectomy has not been shown to have more than a transiently beneficial effect on the arthritis or the leukopenia, although in the case here reported there was a disappearance of the abnormal skin pigmentation and an improved liver function as tested by the removal of bromsulphalein from the blood.

SUMMARY

1 A case that came under my observation corresponding in essential details with the cases reported by Felty in 1924 and the case reported by Hanrahan and Miller in 1933, was characterized by chronic arthritis, splenomegaly and leukopenia.

2 There was an apparently temporary effect of splenectomy, first performed in this syndrome by Hanrahan and Miller.

3 The gross and microscopic appearance of the spleen removed from my patient was similar to the picture described by Hanrahan and Miller.

4 A persistent although variable, eosinophilia occurred in the case reported here, and small groups of eosinophils were observed in the splenic pulp. In Felty's original description, two of his three cases in which differential counts were reported exhibited an eosinophilia. In the cases reported in the literature there is not uncommonly an association of neutropenia and eosinophilia with chronic arthritis and of eosinophilia with splenomegaly.

5 A diminished sugar tolerance, or delayed sugar removal was exhibited in my case.

SIMULTANEOUS, BILATERAL SPONTANEOUS PNEUMOTHORAX

REPORT OF A CASE, WITH A BRIEF DISCUSSION OF THE LITERATURE

D. E. MARKSON, M.D.

Associate in Medicine Northwestern University Medical School

AND

WARREN JOHNSON, M.D.

Attending Surgeon Norwegian American Hospital

CHICAGO

Bilateral spontaneous pneumothorax, occurring in the apparently healthy, is an extremely rare disease. Kjaergaard,¹ who reviewed the literature,² found only three such reported cases. McMahon,³ who recently added another case to the group, found less than fifty bilateral cases reported from all causes. The case to be presented here is therefore of unusual interest, as the bilateral spontaneous pneumothorax not only occurred in an apparently healthy young man but probably became bilateral within a few hours after the onset.

REPORT OF CASE

A young man aged 19, a tall thin athletic college student, walked into our office, July 7, 1933, in a condition on admission so critical that the following history had to be obtained from his mother, who accompanied him.

One of his maternal uncles had diabetes while a maternal uncle had asthma. A maternal uncle had died of diabetic coma, another maternal uncle had died suddenly of suffocation supposedly due to tuberculosis. His sister aged 20, had diabetes and a brother aged 12 had asthma.

He had not had any acute illness anteceding his present trouble nor had he had any chronic respiratory or other illness in the past outside of measles, chickenpox, whooping cough and scarlet fever. Since the age of 10 years he had not had a single day's illness, neither had he had any injuries or operations. In the latter part of June he completed a course in college, where he had been an exceptional student and had won two medals in major sports. As he had been a star athlete, his habits were excellent, he neither drank, smoked, used tea or coffee nor dissipated in any way, he averaged ten hours' sleep a night.

July 6, the patient had pitched a nine-inning game of baseball and felt physically fit after this strenuous exercise. He

retired that night feeling as usual. On finishing his bath the next morning at 10 o'clock, he noticed a severe left lumbar pain, which persisted and, in the course of an hour, was accompanied by dyspnea. By noon the dyspnea had become of such severity that his mother decided to bring him to our office, a distance of approximately a mile. The dyspnea increased steadily on the way, so that progress was made a few steps at a time. The severe constricting pain across the chest had become so intense that he felt he would die before reaching his destination. He perspired profusely, and his mother noticed a livid pallor of his face and lips. With desperate effort he finally reached our office at 4 p. m., having taken nearly two hours to complete the walk.

The patient was 69 inches (175 cm) tall and weighed 124 pounds (56.2 Kg). He was having a desperate struggle in his attempt to breathe. Respirations were carried out with tremendous effort by short jerky gasps, all the accessory muscles of respiration being used. He appeared apprehensive and perspired profusely, his face had a marked cyanosis, noticeable even under a sun tan. The distended thorax appeared to be fixed without any excursion except for the retracted intercostal spaces and suprasternal notch during inspiration. The infrasternal angle was obtuse, with diaphragmatic motion corresponding to the gasps that were made in an effort to breathe. There was no cardiac impulse visible. His pulse was 132, irregular, of poor volume and thready, his blood pressure was 100 systolic, 80 diastolic. The patient assumed a sitting up position leaning slightly forward. An attempt to place him in the recumbent position nearly ended in disaster, as his pulse became weak and thready, the cyanosis became intense and he began to expectorate a frothy mucus. The physical examination, therefore, was continued with the patient in the position described. The right lung was tympanic throughout, anteriorly and posteriorly, with the exception of an area extending from the fifth to the tenth dorsal vertebra about 3 inches in width along the spine, over which dullness was distinct. There were no breath sounds audible anteriorly or posteriorly over the right lung. The upper left thorax was tympanic above an area extending in an almost straight line from the fifth rib anteriorly to the sixth dorsal vertebra posteriorly. Another tympanic area could be percussed below a line running from the sixth rib to the tenth dorsal vertebra posteriorly. Over the intervening space there were dullness, harsh distant breath sounds and bubbling rales. The mediastinal area was tympanic, so that the heart dullness could not be outlined. The temperature was not taken at this time.

The patient was placed under the fluoroscope in the erect position for examination. The right lung was observed to be almost completely collapsed, approximately 80 per cent, and the left about 50 per cent. The left lung was represented as a triangular shadow with the base directed toward the

spine. The upper margin extended in a straight line across the thorax at the level of the fifth dorsal vertebra while a line extending from it diagonally toward the cardiophrenic angle constituted the lower border. The upper border could be seen moving within a narrow range while the lower border appeared fixed. On the upper margin toward the spine was a cystic appearing mass about 1 inch in diameter which moved with the lung and was apparently protruding from it. Figure 1, copied from Kjaergaard, is an identical picture of what was seen fluoroscopically. A few ounces of fluid was visible in the left base, which could be seen scattering with each slight diaphragmatic excursion. There was very little movement in the right diaphragm but a slight fluid level could be seen at the costo-phrenic sulcus. The mediastinum was displaced to the left and the heart shadow was partially obscured. The heart

appeared very much embarrassed, with limited excursions. The trachea appeared in the midline with very little displacement. A roentgenogram (fig. 2A) confirmed the fluoroscopic examination. At the level of the fifth dorsal vertebra and posterior to the fifth rib can be seen the mass described under the fluoroscopic examination.

The patient was given one-fourth grain (0.016 Gm) of morphine and taken to the Norwegian American Hospital, where he was immediately prepared for thoracentesis. Further examination at this time revealed a coin sound in the right side, but no succussion splash could be heard. With the patient

Fig. 2—Appearance of chest. A July 7, 1933 with bilateral spontaneous pneumothorax. B July 17 with lungs partially reexpanded. C August 8 with lungs still partially reexpanded and D August 31 with lungs fully reexpanded.

in a sitting position a trocar was inserted in the posterior axillary line, sixth interspace, and with a Luer-Locke type of Dieulafoy's aspirator approximately 3,000 cc of air was removed from the right pleural cavity. A like puncture was done on the left side, approximately 2,000 cc being removed. The result was quite dramatic, as the patient immediately began to breathe easy, his color changed to its normal hue, and he demanded to be left alone so that he could rest. He was placed in a fully recumbent position, lying on one pillow, and promptly went to sleep. His course from this point has been uneventful. A record of his temperature while in the hospital, eleven days, showed no elevation above 98.6 F after the first three days, 99.4 being the highest point reached. Following the aspiration, his pulse became regular and of full volume, the rate varying between 72 and 80. His respirations likewise decreased from 44 to 26 and, though shallow, were regular. The roentgenogram made July 17 (fig. 2B) shows the partially reexpanded lungs, while figure 2C illustrates the condition on August 8.

The laboratory data were as follows. Examination of the urine was negative. Examination of the blood showed red blood cells, 5,520,000, hemoglobin, 80 per cent, white blood cells, 10,200, differential: small lymphocytes, 24 per cent, large lymphocytes, 7 per cent, large mononuclears, 1 per cent, polymorphonuclears, 68 per cent. The Wassermann and Kahn reactions were negative. No tubercle bacilli were found on direct smear of the tracheal mucus or after concentration and digestion a guinea-pig that was injected intraperitoneally.

Fig. 1—Valve vesicle natural size (reproduction from Kjaergaard).

spine. The upper margin extended in a straight line across the thorax at the level of the fifth dorsal vertebra while a line extending from it diagonally toward the cardiophrenic angle constituted the lower border. The upper border could be seen moving within a narrow range while the lower border appeared fixed. On the upper margin toward the spine was a cystic appearing mass about 1 inch in diameter which moved with the lung and was apparently protruding from it. Figure 1, copied from Kjaergaard, is an identical picture of what was seen fluoroscopically. A few ounces of fluid was visible in the left base, which could be seen scattering with each slight diaphragmatic excursion. There was very little movement in the right diaphragm but a slight fluid level could be seen at the costo-phrenic sulcus. The mediastinum was displaced to the left and the heart shadow was partially obscured. The heart

with this sediment, July 29, was killed, August 31, and at post mortem showed no evidence of tuberculosis. An electrocardiogram taken on the third day of hospitalization showed low voltage in the first lead but was otherwise negative.

He was discharged from the hospital July 17, and was kept in bed at home for thirty-five days. He was given no medication in this rest period. A daily three-hourly temperature record showed no rise above 98.6 during this time. He had no cough nor was there any expectoration. An examination August 31, showed hyperresonance of the lungs anteriorly and posteriorly, with heart dulness within the range of normal. The breath sounds were normal and there were no rales. The roentgenogram (fig. 2D) made on this date shows the lungs fully reexpanded. Outside of the dense hilus markings, they appear quite normal, with no evidence of tuberculosis.

The patient was allowed to sit up, August 21, and his exercises were increased daily until on September 19 he was able to walk 2 miles without discomfort. He has apparently completely recovered but has not been permitted to engage in strenuous exercises. He was planning to reenter college in the autumn quarter.

COMMENT

The sudden onset of this disease in an apparently healthy youth, the afebrile course without complicating seropneumothorax or pyopneumothorax, the negative roentgenographic evidence of tuberculosis, as well as the absence of tubercle bacilli in the sputum either by direct smear or after concentration and digestion, and the absence of changes in the guinea-pig injected intraperitoneally, together with the rapid, uneventful recovery of the patient, clearly establish the diagnosis here of a simultaneous, bilateral spontaneous pneumothorax simplex.

A simultaneous pneumothorax is defined by Olbrechts⁴ as one in which an entrance of air takes place in the two pleural cavities at once or the second pleural cavity is filled with air while the other hemilateral pneumothorax is partially absorbed. Our case is probably of the latter type, as the pneumothorax undoubtedly occurred on the left side first and became bilateral in from four to six hours.

The remarkably short time in which the condition progressed establishes this case as one of exceptional rarity. In Elte's case, a youth, aged 19, a right-sided pneumothorax suddenly developed and three days later a left-sided pneumothorax. The lungs reexpanded gradually so that in four months recovery was complete. In Hayashi's⁶ fatal case there was a three weeks interval between the pneumothoraces. Watson and Robertson's⁷ case was of the alternating type, with fourteen distinct attacks of pneumothorax in two years, at one time there was a bilateral pneumothorax, extensive on the right side and partial on the left. McMahon's case became bilateral about four weeks after the onset of a left-sided pneumothorax, but recovery occurred in three months.

The prognosis for apparently healthy patients with pneumothorax is very good, and this is a characteristic feature of the disease. Kjaergaard's forty-nine patients with unilateral spontaneous pneumothorax have lived from three and one-half to twenty years. In one case, tuberculosis developed about three years after a unilateral pneumothorax, but this was considered a purely accidental infection. In bilateral cases, however, there

is danger of suffocation, and immediate attention is needed.

The procedure carried out in our case as was done by Elte, was a life-saving measure. Permanent aspiration by a water or electric suction pump may have to be instituted when the ordinary procedure fails. It is worthy of emphasis that these patients do not need institutional after-care, as recovery is rapid and spontaneous.

ETIOLOGY

Very little indeed is known about the supposedly idiopathic types of spontaneous pneumothorax. So few patients die from this disease that the pathologic-anatomic observations have been established through approximately ten cases.

Kjaergaard reviews this material and concludes that ruptured valve vesicle cysts, due either to scar tissue, emphysema or congenital malformation of the lung tissue, account for the cause in many cases of this disease. The origin of congenital lung cysts is quite unknown according to Koontz,⁸ who reviewed 108 cases. Some are considered as the fetal retention type, while others are regarded as developmental anomalies of the bronchial tree with the fetal structures still preserved. Congenital disposition to valve vesicle is suggested in Kjaergaard's⁹ supplementary review. He cites cases in which a spontaneous pneumothorax simplex developed in more than one member of the family. In our own case, the history of the sudden suffocation of a maternal uncle and the fluoroscopic and roentgenographic evidence of a left apical cyst point to a congenital cyst as the possible etiologic factor.

Emphysema is a rare cause, however, several fatal bilateral cases have been reported. Emerson's¹⁰ fatal case followed asthma.

Traumatic bilateral cases sometime run a benign course. Such cases have been reported by Mills,¹¹ Hawes,¹² Leclerc,¹³ Elte and Benedict.¹⁴

Kjaergaard states that "although pulmonary tuberculosis is the most frequent cause of spontaneous pneumothorax in the late stages of the disease, yet a minimal subpleural tuberculosis as a cause occurs rarely and takes the course of sero- or pyo-pneumothorax." Benign cases of spontaneous pneumothorax have been reported occurring in tuberculous patients. It is probable that in such cases a valve vesicle may have been the cause, the tuberculosis playing no role whatever.

SUMMARY

The case presented is of unusual interest because 1 The probable etiology of the bilateral pneumothorax is a congenital cyst. 2 We could not find a case on record with an interval of from four to six hours between the pneumothoraces. 3 In no other case reported was the recovery so rapid and uneventful. 4 This is probably one of the most clear-cut cases of simultaneous, bilateral spontaneous pneumothorax simplex on record.

KERATODERMA BLENNORRHAGICUM

REPORT OF A CASE

JOHN GODWIN DOW'NING, M.D.

BOSTON

Keratoderma blennorrhagicum is an interesting dermatosis associated with gonorrheal arthritis and occurs almost exclusively in the male sex, although three cases have been reported in females by Lees¹ Issac² and Robert³. It occurs at all ages and probably more frequently than the literature shows because it is unrecognized in the very mild types. Up to the present time there have been about eighty-three cases reported in the literature nineteen of which have been described in America.

This disease has been described under various appellations, the most common being keratoderma blennorrhagicum with the occasional substitution of "keratoma," "dermatitis keratosis," "hyperkeratosis" or "exanthema" for the keratoderma part, and "gonorrheal" for the blennorrhagicum. Berman⁴ called it "dermatitis papillaris parakeratosis," while Rostenberg and Silver⁵ added the name "dermatitis rupioides arthropathica." From a study of the pathology, none of these names are entirely satisfactory since not one of them is either fully descriptive or in entire accord with the manifestations. There is no doubt at the present time that the condition is due to gonorrhea, the lesions show a definite inflammatory reaction in the epidermal and papillary layers, together with a pronounced parakeratosis not a hyperkeratosis. The term "keratodermatitis gonorrhoica" is suggested, therefore, not to add to the already burdensome list of descriptive names but to lead to the adoption of a simpler term both descriptive and showing the causative agent.

To Vidal,⁶ a French dermatologist, goes the credit of being the first to identify and describe this syndrome, in 1893. He considered it, however, a syphilitic manifestation and used antisyphilitic treatment without success. Following his report, twenty other cases found their way into the literature, but the first case in America was not reported until 1912, when Simpson's article⁷ appeared. This report was accompanied by a full bibliography. Roark's⁸ case followed in the same year and since then contributions have been made by Harse⁹ Simpson and Beeson¹⁰ Giger,¹¹ McDowell,¹² Kretschmer,¹³ Stillman and Zeisler,¹⁴ Keim,¹⁵ Willmott,¹⁶

Millis,¹⁷ Rostenberg and Silver,⁵ Scholtz,¹⁸ Barrett,¹⁹ Ronchese,²⁰ Sullivan, Rolnick and White²¹ and Chambers and Koetter.²² Rostenberg and Silver presented a thorough discussion of the many problems of the disease. Keim has an inclusive bibliography of the fifty-eight cases to that date.

REPORT OF CASE

W. K., a man aged 41, Lithuanian, a butcher, had had a chronic cough for the past two years, but otherwise the past history was irrelevant. He had had a discharge from the urethra for an uncertain length of time and pains in his back, right hip and knee joints for the past three months. Previous to that, he had more or less indefinite joint symptoms, with an eruption on the skin of the legs for which he was hospitalized one year before. The diagnosis on his discharge nine months before was infectious arthritis with early hypertrophic arthritis and a tubercle of the skin. At that time he was not seen by the dermatologic service.

The present illness began one week before admission, Jan. 23, 1930 when the patient noticed a discharge from the penis with some burning and frequency on micturition. Several days later while lifting a heavy load, he experienced a sharp pain in the region of the right hip. The pain was so severe and constant that he was admitted to the hospital with the diagnosis of acute urethritis and acute arthritis. The manifestations on admission were (1) a copious urethral discharge showing gram-negative extracellular and intracellular diplococci (2) great tenderness and pain on motion of the right hip joint and both knees (3) roentgenologically a chronic bronchitis with no pathologic changes in the joints (4) a moderate temperature.

During the following five weeks the patient had a septic temperature and suffered greatly from arthritic pains in the hip, knee and ankle joints. He was treated with urethral washes, salicylates and intravenous oxalates without relief, although the swelling of both knees subsided. Several weeks after the initial discharge, what were described as large blebs containing small amounts of bloody serum appeared on the soles of both feet and were treated with potassium permanganate. They continued to enlarge and were described as becoming very keratotic and septic. The patient was then seen by the skin service March 27. At that time he showed involvement of the soles of both feet, on which there were large, irregular crusted excrescences. The majority of the lesions were discrete and varied in size and thickness. On the palms were small keratotic areas, on the lower part of the back were numerous crusted lesions more or less varied in size and of a rupia-like nature surrounded with a fine zone of erythema. The general condition of the patient was fair, he had a mild elevation of temperature but the arthritic pains were quite severe. There was no urethral discharge but the seminal vesicles were greatly enlarged, fluctuant and tender. During the following three months the patient was treated with potassium permanganate soaks and a gonorrheal vaccine. Calcium gluconate was also injected intravenously, as recommended by Baer²³ for its use in arthritis. The injection of calcium gave no relief. The toe nails finally became exfoliated. The patient became more and more emaciated until he finally reached a point at which it seemed necessary for some further therapy. July 2 an operation was performed by Dr. Augustus Riley at which time a double vesiculectomy was performed and the prostate, which was swollen and boggy, was incised and drained at the same time. The patient had a stormy period of convalescence for a few days during which time he showed a veritable shower of new lesions on the skin but the tempera-

ture promptly dropped after forty-eight hours. Improvement from that time on was continuous and quite rapid. He gained in weight, was able to get up and around with the aid of a cane, and was finally discharged to the outpatient department, September 3.

COMMENT

Noteworthy in this case is the favorable effect of a vesiculectomy as contrasted with other forms of therapy. This case was shown at a meeting of the New England Dermatological Society April 16, 1930. At that time the patient was so emaciated and weak that it was necessary to carry him on a stretcher to the meeting. He was again shown at the meeting of the Atlantic Dermatological Conference in Boston November 10. The patient, at this time, had gained about 30 pounds (13.6 Kg.), showed no lesions, and was practically free from joint symptoms, although he still used a cane. After the operation the vaccine therapy was continued, and it seemed to be more beneficial than it was previous to the operation. It is possible that the mild eruption that he had on his first entrance to the hospital may have been a beginning keratoderma blennorrhagicum. It is likely that many eruptions associated with

reheal infection (single or repeated) or showed evidence of pathologic changes in the genito-urinary tract which was very probably gonorrhea.

Cases have been reported in which arthritis was absent,²⁵ but it is usually present and in the form of an acute polyarthritis with a predilection for the joints of the knees and the ankles. The eruption may be generalized or localized but usually affects the palms of the hands and the soles of the feet. In a series of cases the soles were effected in thirty-four, the toes in thirteen, the back in twelve, the legs below the knees in ten, the hands in eight and the penis in nine. Lesions of the mucosa of the mouth and of the penis have been reported by Berman,⁴ who cites four other cases.

Generalized eruptions begin with a red or white macule, which is closely followed by a vesicle and pustule that enlarges rapidly with resulting central crusting. This crust enlarges and becomes depressed until the lesions show an adherent depressed crust surrounded by a definite ring of pus and a fine, red erythematous zone. On the soles this crust becomes so large that it produces the "relief map" patches so well described by French authors. The generalized eruption is frequently ushered in by a rise in temperature, preceding by some hours a generalized shower of new lesions. Arthritis, in some cases, becomes chronic, and mental depression accompanies these cases. Suicide has been reported in one case.²⁶ The other gonorrheal complications of the visceral organs and the eye have been frequently reported. The same is true for relapse after a complete cure, which happened in the very first case described by Vidal.⁶ When the skin lesions resolve and the crusts described separate, a reddish moist surface remains with some pigmentation, which disappears entirely.

Fig. 1—Plantar keratosis showing relief map appearance

arthritis are frequently misdiagnosed on account of the rarity of the disease and the low index of suspicion.

There are various types of skin eruptions associated with gonorrhea. Buschke,²⁴ in 1899, classified all skin eruptions associated with gonorrhea into four main types: (1) erythematous type, (2) urticarial and erythema nodosum type, (3) bullous and hemorrhagic type, and (4) keratotic type. However, while gonorrheal infection may give rise to such a variety of types of skin lesions, the keratotic form represents a distinct clinical entity. The peculiarly distinct type of the lesions, the very definite course, the almost constant association with arthritis and the fact that transitional forms had never been observed militate against the conception that it stands in any relation to the other types except etiologically.

The clinical syndrome is usually a triad of urethritis, arthritis and dermatosis. The urethritis is either acute or subacute, with a history of previous attacks in almost all cases. The cases reported in which the arthritis and dermatosis occurred without an associated urethritis by Buschke,²⁴ Adamson,²⁵ Scholtz¹⁸ and Graham Little²⁶ have either had a definite history of previous gonor-

ETIOLOGY

There is no question that the syndrome of this dermatitis is gonorrheal. There was hardly any dispute about this until Adamson raised the contention that it was a form of arthropathic psoriasis. Falk²⁷ also was firm in his belief that keratoderma blennorrhagicum has nothing specific about itself, being only a typical form of psoriasis arthropathica. Adamson's arguments were based on the facts that

1 Cases of arthropathic psoriasis with lesions on the palms and soles strongly simulating keratoderma blennorrhagicum, are sometimes seen.

2 In many cases of keratoderma blennorrhagicum of the limbs and trunk, lesions arise which are indistinguishable from psoriasis.

3 The differential diagnosis between the two clinically is often impossible.

4 Histologically, the two diseases are similar.

However the apparent reasonableness of this contention is easily deflated by a more critical analysis of these factors. To begin with, Keim, after extensive study, came to the conclusion that there is no histogenic basis for believing that keratoderma blennorrhagicum and psoriasis are in any way related. The clinical similarity between a typical case of keratoderma blennorrhagicum and a typical case of psoriasis is no greater than between the latter and seborrheal dermatitis of

²⁸ Falk A. Archiv f. Dermat. u. Syph. 129 299 1921

similar circumstances. The almost invariable association of a gonorrheal urethritis with keratoderma blennorrhagicum is something more than a coincidence, and even if this is so, the parallel onset and relief of the gonorrheal infection, the arthritis and the eruption is certainly not. The reported finding of gonococci in the lesions is at least suggestive, then again, the great preponderance of the localized type in keratoderma blennorrhagicum, which is not true of psoriasis, the characteristic course involuting after several months, the relatively infrequent recurrence, and the almost constant association of another attack of urethritis. The chronological relation—that is, the rash always following the gonorrheal infection, the frequency of the vesicles in the development of the lesions and the usual presence of a positive complement fixation test—all point definitely to the etiologic relation of keratoderma blennorrhagicum to gonorrheal infection.

PATHOGENESIS

Keratoderma blennorrhagicum is undoubtedly due to gonorrhea, but whether it is toxic, septic, metastatic or allergic is unknown. If the condition is due to hematogenic dissemination from some primary focus, then the organisms should be found in the lesions. However, only five reports have shown this to be true, and only one, that of Wadsack,²⁹ was a typical case of keratoderma blennorrhagicum. All the others occurred in gonorrheal infection associated with skin eruptions not of the keratoderma blennorrhagicum type. For instance, Scholtz³⁰ was able to make a culture of gonococci from the connective tissue abscesses in the case of gonorrheal urethritis, which, however, was associated

found gonococci in the smears from pustules, vesicles and abscesses. Dubois³¹ and Campbell³² have also published reports. Even if all these had been true cases of keratoderma blennorrhagicum, the percentage is still small. This theory may be acceptable only if one

Fig. 3—Confluent lesions between the toes of both feet

accepts Scmazzone's³³ opinion that it is an allergic expression of a sensitized skin and that consequently the gonococci are rapidly killed in this sensitized skin.

TREATMENT

Many forms of treatment have been used, and, as would be expected, they are focused at the causative agent. Rapid removal of the focus should be the main purpose regardless of the type of infection. If it is suspected that the vesicles and the prostate are involved, it would seem that the logical thing would be to drain these organs. With this focus removed, the skin lesions heal with little or no attention.

CONCLUSION

In a case of keratoderma blennorrhagicum a rapid recovery followed operative procedure of double vesiculectomy and prostatotomy.

A Real Argyll Robertson Pupil—According to Wilbrand and Saenger, a true Argyll Robertson pupil must have the following characteristics: There must be loss of the direct and indirect light reactions. The convergence reaction must be increased and sustained. The pupillary diameter should be less than 3 mm. The size of the pupil does not vary from time to time. The psychic and sensory pupillary play is lost or lessened. It must be admitted at the outset that many writers on this subject do not subscribe to this definition of a true Argyll Robertson pupil, the question of miosis being the point of disagreement. Wilson stated that miosis is incidental and is not a necessary feature of an Argyll Robertson pupil. On the other hand, with equal assurance Behr, Lafon, Wilbrand and Saenger and many others asserted that miosis is as important as the loss of the light reaction. This is an important observation because on it depends the decision as to whether the pupil is a true or syphilitic or a false or nonsyphilitic Argyll Robertson pupil. McAndrews, L. F. *Argyll Robertson Pupil*, *Arch. Ophth.* 10: 520 (Oct) 1933.

SPONTANEOUS RENO-INGUINAL FISTULA

ABRAHAM RAVICH, MD

AND

PERRY KATZEN, MD

BROOKLYN

Renal fistulas may be traumatic or spontaneous in origin, the traumatic type following accidental injuries to the kidney or operative procedures. In the present discussion the spontaneous type will be the only one considered.

Spontaneous renal fistula was known even to the ancients, Hippocrates having described it as a complication of renal calculus. Although it was always considered a rarity, the older medical literature contained a fair number of case reports. Rayer,¹ in his textbook on diseases of the kidney, published in 1839, discussed the subject at great length and cited a number of cases that came under his own observation. In 1889 Rollin² was able to collect thirteen contemporaneous cases, and Chazet³ in 1900 reported from the literature of the time twelve cases associated with renal tuberculosis. This is in marked contrast with the paucity of such reports in the more recent literature, only five cases having been cited in the last thirty years. Such a change is undoubtedly due to the earlier recognition and treatment of the pathologic changes underlying the formation of renal fistula by the more modern urologic methods.

ETIOLOGY

A lesion in the kidney itself is prerequisite to the formation of a fistulous tract from that organ. By far the most common is nephrolithiasis, which is the causative factor in the majority of cases. Thus, it was present in seven of the thirteen cases reported in Rollin's series and was found in four of the five cases reported in the last thirty years. Less common causes are pyonephrosis, pyelonephritis, renal tuberculosis and hydronephrosis. Rayer cited a unique case due to infestation of the renal pelvis by roundworms (*Strongylus gigas*).

PATHOGENESIS

The formation of a renal fistula is directly traceable to a perforation either of the renal pelvis or of one of its calices, the former being more common and usually occurring on the posterior surface. In most instances only a single opening is found but there may be several. Rayer stated that the posterior surface of the pelvis may be so riddled with orifices as to resemble a sieve.

A perforation is usually the result of ulceration of the pelvis or calix from within. When the ulcerative process involves a calix or an intrarenal pelvis, the overlying renal parenchyma and even the kidney capsule may be ruptured. Infection plays the major role in bringing about these changes, the process often consisting of abscess formation with considerable destruction of kidney tissue. However in extensive hydronephrosis with a marked thinning out of the pelvis and calices, traumatism to the kidney, no matter how slight, is usually the direct cause of rupture. In the presence of calculi an additional factor is undoubtedly

involved, namely, pressure necrosis, with resultant thinning out of the pelvis, calices and overlying parenchyma. Rupture finally occurs at a point weakened by the destructive changes as a result of the infection that often accompanies calculous disease. In nephrolithiasis, trauma may be the exciting agent in producing the perforation, such a case having been reported by Guy.⁴

Extravasation of urine into the perirenal tissues develops at the site of rupture. When the ureter is patent, such extravasation is of slight degree and if the kidney is functionless there may be no urinary leakage whatever. If there is accompanying ureteral blockage, however, the extravasation is very extensive and results in a severe fulminating infection. This is well illustrated in the case reported by Henline,⁵ in which spontaneous rupture of the superior calix by three small calculi occurred in a patient who also presented a stricture in the upper ureter with a calculus

Outlining of fistulous tract by injection of iodized oil into inguinal opening of sinus. Communication of upper end with the right kidney and its relation to the nephrolithiasis.

just above it. A widespread extravasation developed into the retroperitoneal space, groin, scrotum and perineum and terminated fatally. Rarely, as occurred recently in one of our cases associated with a small renal calculus, the rupture of a calix may extend through the renal parenchyma to the periphery of the kidney but fails to perforate the fibrous capsule, resulting in a collection of urine between the kidney and its capsule. Dourmashkin⁶ has very aptly termed this condition "subcapsular extravasation."

As a result of the extravasation of urine and pus into the perinephric tissues, an extrarenal abscess of varying extent develops. The outcome of such a case depends on the path taken by the suppurative process.

Very rarely there is extension to neighboring viscera, followed by perforation into these organs with a resultant renovisceral fistula. Thus, as in another one of our cases a communication developed with the lung, eventuating in a renobronchial fistula. The left kidney may establish a fistulous tract with the stomach, in the case of the right kidney a renoduodenal fistula may develop. Either kidney may take part in the formation of a renocolonic fistula.⁷ A kidney situated in the pelvis has been known to perforate into the rectum. Through the fistulous channel urine and pus are carried into the invaded organ, and in cases of nephrolithiasis calculi may similarly be conveyed into the perforated viscus, later to be expelled from these organs. For example, calculi may be coughed up from a bronchus in renobronchial fistulas, be expelled in the vomitus in cases of renogastric fistulas, or be passed in the stools in renocolonic fistulas. At times a fistula may extend directly into the peritoneal cavity, followed by a usually fatal peritonitis.

A renovisceral fistula is very exceptional, the type ordinarily observed opens on the external surface of the body and may be called renocutaneous. All of Rollin's cases were of this variety. The inflammatory process that accompanies the perforation of the pelvis or calyx generally limits itself to the retroperitoneal space and forms a perinephric abscess, which usually presents itself as a tumefaction in the lumbar region, most commonly over Petit's triangle. Occasionally, however, the suppuration may extend along the plane of the iliopsoas muscle and point on the inner aspect of the thigh near the lesser trochanter or rarely may point in the inguinal region above Poupart's ligament. The abscess frequently opens spontaneously but more often is drained by incision. Although usually the discharge of pus is mixed with urine in cases in which the ureter is patent, the discharge may contain no urine whatever if the kidney is functionless. The chronicity of the fistula is noteworthy, drainage may continue for years, stopping in most instances only after removal of the offending kidney. In nephrolithiasis, fragments of calculi may be eliminated spontaneously through the fistula, occasionally followed by healing of the fistula and cure. At other times, surgical investigation of the cause for the persistence of the sinus will reveal a calculus in the depths of the sinus, removal of which may bring about rapid closure of the fistula. Such a case has been reported by Orr-Ewing⁸ in which the fistulous tract was opened wide and a large calculus found and removed, followed by rapid healing of the fistula.

Although Ravich and also Morris⁹ stated that spontaneous reno-inguinal fistulas do occur neither gave any case reports of this type of fistula. The only report actually cited in the older literature is that of Rollin, who described a case occurring in voluminous hydronephrosis which terminated in cure following nephrectomy. Since Rollin's report, the only other case recorded has been that by Barney and Mixer.¹⁰ In their patient an abscess in the left groin just above Poupart's ligament had been incised twenty-two months

before and much pus evacuated followed by healing of the wound in two weeks. The abscess recurred a year later and was again incised but this time failed to heal, and the wound continued to drain thin pus without the suggestion of any urinary content. A week prior to hospitalization, a progressive transverse myelitis developed. Operation revealed a tuberculous kidney containing a large calculus, and running parallel to the ureter they found a fistulous tract extending from the groin to the renal pelvis. Nephrectomy resulted in prompt healing of the inguinal sinus as well as disappearance of all evidence of the transverse myelitis.

In view of the rarity of such cases, we present the following interesting case, which recently came under our observation.

REPORT OF CASE

M. K., a man aged 48 married Austrian tailor was admitted to the medical service of the Jewish Hospital of Brooklyn Nov. 13, 1930, with the chief complaint of a progressive painless swelling in the right groin of four weeks' duration. For a year prior to admission there had been a constant dull pain in the right lumbar region and loin with occasional radiation down the right thigh. During the past six months the patient had noted slight diurnal frequency and burning on urination, but never any gross hematuria and a loss of 20 pounds (9 Kg.), with accompanying loss of strength. Except for hemorrhoidectomy eight years before the previous history was negative and the family history irrelevant. There was no history of venereal disease.

The patient was fairly well nourished and was not acutely ill. Examination of the head, neck, heart and lungs gave negative results. In the right groin an irregularly rounded mass about 3 inches in diameter was noted just above Poupart's ligament, lying between the anterior-superior spine of the ilium and the external inguinal ring. The mass was hard, fixed to the subjacent tissues as well as to the overlying skin, and was only slightly tender. There was no redness of the skin over the tumefaction. The liver, spleen and kidneys were not palpable. There was some tenderness over the right costovertebral angle but none along the spine. The external genitalia were normal, as were also the extremities. The reflexes were normal. On rectal palpation the prostate was found to be somewhat enlarged but of normal consistency and evidently not malignant. The expressed prostatic secretion was essentially negative microscopically.

On admission the temperature was 100 F., pulse 80, respiration rate 28. The blood pressure was 112 systolic and 70 diastolic. Blood count revealed 4,800,000 red cells, 80 per cent hemoglobin and 9,800 white cells with 61 per cent polymorphonuclears, 34 per cent lymphocytes, 4 per cent mononuclear and transitional cells and 1 per cent eosinophils. The specific gravity of the urine was 1.022, it was acid in reaction and showed no albumin nor sugar. Microscopic examination was negative. The Wassermann and Kahn reactions of the blood were negative. The blood sugar was 93 and the urea nitrogen 166 mg. per hundred cubic centimeters of blood. Roentgenograms of the pelvis revealed no evidence of inflammatory or neoplastic changes except for a slight degree of lumbar scoliosis to the left. The entire vertebral column was likewise normal. Roentgenograms of the urinary tract demonstrated the right kidney to be normal in size and position with a large coral shaped calculus filling the entire pelvis and calices. The left kidney was somewhat enlarged and slightly ptosed. Intravenous urography showed no function in the right kidney but a normal left renal pelvis and calices. At the time the pathologic condition of the right kidney was considered to be coincidental and of no significant relation to the mass in the groin. Although urinalysis on admission was apparently negative the urine two weeks later and on every subsequent examination showed many pus cells and several erythrocytes.

The swelling in the right inguinal region gradually increased and at the end of five weeks was about one and one-half times its original size, the extension occurring upward, laterally and

medially but still being limited inferiorly by Poupart's ligament. Accompanying this increase in tumefaction, the overlying skin became reddened and the mass quite tender. The temperature remained normal but a slight leukocytosis of 14,100 developed, with 70 per cent polymorphonuclears. Biopsy was decided on, and on Dec. 30, 1930, under local anesthesia the mass was accordingly incised and a large abscess containing several ounces of creamy yellow pus was found just below the skin. An irregular mass of soft jelly-like red and yellow tissue about 1 inch in diameter was found in the abscess cavity and removed for histologic examination. When the cavity was probed a tract was found leading upward into the retroperitoneal space. The wound was packed with iodoform gauze. Pathologic examination of the tissue removed for biopsy revealed that the specimen consisted of fat and fibrous tissue which were infiltrated with blood and polymorphonuclear leukocytes, indicative of acute suppurative inflammation. No specific pathologic condition was demonstrable. Culture of pus from the abscess was sterile.

Following incision the mass gradually disappeared and the patient was discharged from the hospital Jan. 14, 1931, with the wound still draining. He was treated in the surgical outpatient department where the sinus was treated with surgical solution of chlorinated soda several times a week but without any improvement. During this period the patient complained of intermittent dull pain in the right lumbar region and the urine constantly contained many pus cells. In spite of ultraviolet irradiation and other measures applied to the sinus the purulent discharge persisted for fifteen months. In an attempt to outline the course and source of the fistulous tract iodized poppy-seed oil was injected into the sinus and a roentgenogram taken, which is reproduced in the accompanying illustration. This revealed a tract leading upward to and surrounding the right kidney, clearly indicating that the cause of the sinus in the groin was a suppurative process originating in the right kidney. In view of the large stag horn calculus in the functionless right kidney demonstrated by intravenous urography, nephrectomy was decided on to clear up the discharging sinus.

The patient was accordingly admitted to the urologic service and operation performed by one of us (A. R.) March 24, 1932. Under spinal anesthesia a hockey stick incision was made in the right lumbar region. The kidney was exposed and found to be small and contracted and filled with several large irregular calculi. Overlying the region of the middle calyx and extending through the fatty capsule and into the perinephric tissues a perforation was found through which part of the calculus could easily be felt. The overlying perinephric tissue was the site of very extensive adhesions, cartilaginous in consistency, firmly binding the kidney to the lumbar fascia and muscles and peritoneum. Because of these dense adhesions, extracapsular removal of the kidney was deemed too hazardous and intracapsular nephrectomy was accordingly performed and the cavity drained with iodoform gauze. The pathologic examination of the kidney showed "chronic suppurative nephritis with nephrolithiasis, the calices were markedly dilated forming cystlike cavities, and the parenchyma was the site of extensive necrosis."

The postoperative course was smooth and uneventful, the kidney wound healing by primary union except at the site of drainage. Following nephrectomy the amount of discharge from the inguinal sinus diminished materially. To corroborate further the connection between the latter and the perinephric tissues mercuriochrome was injected into the kidney wound and appeared immediately in small amounts from the existing sinus in the groin. The patient was discharged from the hospital, April 29, with a moderate amount of seropurulent drainage from the kidney wound and a scanty purulent discharge from the inguinal sinus. He was subsequently observed in the urologic outpatient department. The kidney wound gradually closed being entirely healed by September 22. The sinus in the groin continued to show a seropurulent discharge until October 18, when it also closed completely. The intracapsular nephrectomy had made it necessary to leave behind a large mass of inflammatory perinephric tissue, and this no doubt accounted for the rather prolonged period of drainage from the kidney wound. The patient was last seen Feb. 25, 1933, at

which time his general condition was excellent. Since nephrectomy he had gained 30 pounds (13.6 Kg.), the operative scars were well healed, and the urine was crystal clear.

SUMMARY

Spontaneous renal fistula has become a distinct rarity since the advent of modern urology, only four cases having been reported during the past thirty years. Nephrolithiasis is the most common etiologic factor. The fistula always begins as a perforation through the kidney parenchyma, causing extravasation of urine and pus, which either gradually finds its way into some viscus or presents itself subcutaneously. The case reported here is the only recorded case of spontaneous reno-inguinal fistula with nephrolithiasis as the causative factor, the only other case similar to it presenting tuberculosis as a concomitant lesion.

The case under discussion first came under observation at the hospital for a swelling in the right groin. Roentgen examination revealed a right nephrolithiasis, which was at first considered incidental. However, when after incision and persistent drainage for fifteen months the fistula was outlined with iodized oil, it was found to communicate directly with a perforation in the right kidney, which was filled with a large coral shaped calculus. The patient was then admitted to the urologic service of the hospital and at operation a densely adherent kidney filled with a friable stag horn calculus was found. The latter had perforated through the kidney cortex and capsule and by extravasation had caused such a cartilaginous-like perinephritis that intracapsular nephrectomy was considered the only safe procedure. The sinus did not close completely until seven months after nephrectomy, owing to the large amount of perinephric tissue necessarily left behind. Uneventful recovery, however, was the end result.

COMMENT

The formation of a spontaneous renal fistula should be considered inexcusable in this age of modern urologic perfection. If the practitioner were to become more urologically minded, kidney lesions of all kinds, including nephrolithiasis and tumors, would not lead to such dire results as now occasionally occur. With proper urinalysis, roentgen examination, cystoscopy and pyelography available, there is no excuse for failure to diagnose nephrolithiasis at an early stage and to institute corrective measures long before the initiation of extensive destruction.

Measles, Influenza and Pneumonia—The experiences during the Great War taught the importance of measles and influenza in rendering conditions suitable for infection of the lung with streptococci, staphylococci, pneumococci or other organisms. Careful investigation shows that even in the absence of epidemics such as those mentioned above, many patients with pneumonia exhibit symptoms referable to the upper respiratory tract for a longer or shorter period before the onset of the disease itself. These symptoms may be those of a simple coryza or common cold, a pharyngitis, disease of the antrum, etc. In over half of a large series of cases at the Hospital of the Rockefeller Institute, the histories mention that one or other of these conditions preceded the pneumonia. The old textbook description of lobar pneumonia arising with great suddenness becoming manifest by a chill in a previously perfectly well individual must be revised. Pneumonia may arise in this manner but in my experience only rarely.—Cole Rufus. *The Outlook for Overcoming Pneumonia*, *Canad. M. A. J.* 30:257 (March) 1934.

CONTAGION AS A FACTOR IN CERTAIN HEART AND JOINT DISEASES

JOHN J. CARDEN, M.D.
SAN FRANCISCO

CASE 1—A woman aged 35, seen in January 1928, had an acute exacerbation of a chronic bilateral parotitis of five years' duration. Between acute recurrences (four), the parotids had remained at the size of half an orange. In each acute attack their size doubled; the patient had a high temperature and there were signs of septic infection until drainage through the parotid ducts was instituted.

During this period of five years varying transient attacks of rheumatoid arthritis were frequent and a mild atrophic arthritis of both hands and feet had developed.

With drainage of the parotids established, this present acute attack subsided. Culture of the parotid secretions revealed a short-lived streptococcus, *Staphylococcus albus* and *aureus* and *Micrococcus catarrhalis*.

Autogenous vaccines and an antirheumatic regimen were continued through August 1928 with a steady, though not marked improvement of both parotid and joint conditions. (The subsequent course of this case will be presented in a later paragraph.)

CASE 2—The sister and room-mate of patient 1, aged 25, seen in January 1928, showed a rheumatoid arthritis of the dorsal spine of four years' duration and of gradually increasing severity until a spinal brace had been necessary for a year. During vacations, however, she had been free from symptoms. No focus of infection was present.

Following removal from home for three months and a long course of the "autogenous" vaccine of patient 1, she remained practically free from rheumatoid arthritis for the next two years. (The subsequent course will be given in a later paragraph.)

CASE 1 (continued)—From December 1928 to March 26, 1930, patient 1 received nearsphenamine intravenously for its antistreptococcal effect. Under this treatment the parotids decreased in size until they were hardly, though somewhat, palpable. The rheumatoid arthritis also improved, with occasional flare-ups as various parotid nodules drained.

In June 1930 the patient developed signs of hyperthyroid activity (basal metabolic rate +28). By July 1930 she was induced to go to the mountains to counteract this and be away from patient 2. She remained away until July 25, 1930, with marked improvement. (The later course will be narrated in a subsequent paragraph.)

CASE 2 (continued)—In March 1930, as patient 1 improved, patient 2 showed a return to rheumatoid arthritis. First a transient subdeltoid bursitis developed, to be followed in a month by a return of the rheumatoid arthritis of the dorsal spine. Vaccine treatment proved useless.

July 16, 1930, cardiac pains were complained of with negative observations.

July 26, 1930, following a four day syndrome of a transient macular rash, headache, backache and a mild rise of temperature ending in hyperpyrexia, the patient became comatose and died in convulsions. Blood cultures, blood chemistry and spinal fluid were all negative. The blood count was low, with a tendency to mononucleosis.

The diagnosis was either (a) the cerebral form of malignant endocarditis or (b) the meningeal form of rheumatic fever.

CASE 3—The mother of patient 1, aged 62, seen, Aug. 24, 1930, had a small though almost fatal coronary embolus. For six months she had noted a shortness of breath on exertion and a villous arthritis of the left knee. The course subsequently has been that of a chronic endocarditis and myocarditis with the occurrence of small emboli during exacerbations.

Whenever patient 1 is worse or away, the mother shows marked improvement with a relapse shortly after the return of her daughter. Recurrent attacks of neuritis of the right arm have ceased with her avoidance of patient 1.

CASE 4—In September 1930 the Japanese occasional house-boy developed an acute prepatellar bursitis. He was referred to his own physician, and full recovery ensued.

CASE 5—In May 1931, an aunt of patient 1 moved into the house. At this time she showed a failing myocardium, with chronic passive congestion of the liver. Her past history was of gastro-intestinal disturbances for the past two years. The cardiac and gastro-intestinal symptoms responded to digitalization but in two months a severe rheumatoid arthritis of the right sacro-iliac joint developed, followed in a month by a similar condition of the left hip. October 20, after an unauthorized shopping tour, the patient was found dead in bed with the signs of an acutely dilated heart.

CASE 6—An aunt of patient 1, aged 58, and a daily visitor, seen, Sept. 20, 1931, had an acutely dilated heart. Her history revealed a mild heart attack six months previously, since which time edema of the ankles had persisted. She was kept alive for a month, when she suddenly sat up in bed, had an attack of jacksonian epilepsy in her right arm (nurse's report) and died with an acutely dilated heart.

CASE 7—The husband of patient 6, aged 58, moved into the house of patient 1 in October 1931. In January 1932 a gradual bilateral parotid swelling developed. Ten days later, following a chill, he showed an acute extensive bilateral parotitis with a temperature of 104°. Next day a pseudo-erysipelas of the face appeared. Following drainage, both parotids returned to normal in ten days and have since remained normal. Two weeks later a mitral insufficiency developed. Since then he has been subjected to occasional attacks of spinal rheumatoid arthritis and infarcts of the spleen.

CASE 8—The uncle of patient 1, aged 55 and a fairly frequent visitor, was seen, Feb. 21, 1932, suffering from a sudden transient left hemiplegia of embolic origin. His course was that of a mild endocarditis and myocarditis, with frequent though small, embolic manifestations. The blood and spinal fluid Wassermann reactions were negative. He was kept in bed until August 8, with steady improvement. September 9, he overexerted and died of an acutely dilated heart.

CASE 9—An aunt of patient 1 had moved into the house in October 1931. She was seen in January 1932 with edema of the legs and a failing myocardium. She responded to digitalization, though later developing rheumatoid arthritic attacks. In December 1932, following the extraction of two abscessed teeth, a mild mitral insufficiency developed. She still responds satisfactorily to digitals.

CASE 1 (continued)—In December 1932, following the extraction of two abscessed teeth, a subacute mitral endocarditis developed, with a tendency to small emboli following any unusual strain. The myocardium is clinically undamaged to date, and between recurrent exacerbations of endocarditis the heart valves appear normal. Yearly roentgenograms of the patient's teeth have always shown a newly abscessed tooth.

CASE 10—A brother of patient 1, aged 40, seen in July 1933, had a transient suprapatellar bursitis and a past history of occasional neuritic pains. His heart was not examined.

SUMMARY

Nine cardiac and rheumatoid arthritic cases occurred in one family group. In this group, only one patient has a definite and constant focus of infection. Since June 1930, from which time this focus of infection has been better drained and varying members of the group have come into more intimate contact with this patient, four have died of cardiac disease, one is practically bedridden with cardiac disease, two are up but with serious cardiac conditions, one is still able to work but has a pronounced cardiac lesion, and seven have had varying attacks of rheumatoid arthritis.

Furthermore, when patient 1 is away or in bed, all the others have shown marked improvement until her return.

CONCLUSIONS

1. In rheumatoid arthritis, (a) the causative focus of infection in certain cases is not in the individual but

As this paper deals with contagion within a family group, all cases have been arranged in their relation to the infective member, patient 1.

Flood Building

BLOOMFIELD HILLS, MICH

These boys had come from homes provided with ample well prepared and properly balanced meals, yet they had not gained at a normal rate. Gaining diets and weight changes could be further studied only by expressing the diet in terms of carefully estimated calory values.

[illegible]

The gaining follows a curve, first rising rapidly, then gradually approaching the horizontal line. This curve

2 Miss Dorothy Waller University of Michigan

might even possibly be expressed in an algebraic formula. This weight gain is swift and not to be confused with the weight any boy gains at a normal rate. The average weight gain is one-fifth pound (90 Gm) a day.

The value to the individual boy of a gain in weight varies, occasionally the general improvement is startling. The benefit, of course, can be only a clinical impression. Not uncommonly with a substantial gain in weight in very thin boys there appeared an interesting change of mood toward a more quiet and receptive quality. The amount of gaining varies also widely

Chart 2—Cream and butter diet, J D S aged 17, height 74½ inches (189 cm), heavy line weight broken line away from diet table

among individuals on the same diet. This fact, however, does not affect the curve mentioned previously.

The weight acquired at the diet table was subsequently held when the boys left the table, and normal gaining began at the newly acquired level. The weight lost in reducing diets is usually replaced by the youngsters after they are released from the table. In no instance was the diet carried beyond the amount desired, whether a thin boy can be made a fat boy is not revealed in this series.

During the current year, for purposes of economy and because there were no pronounced instances of underweight in the school, this elaborate diet table was replaced by a simple cream and butter diet, the cream

THE PSYCHOLOGY OF THE DIET TABLE

The most intriguing and interesting part of the diet is causing the boys to eat the food. A long, heavy oak table is placed in a large room with colorful, descriptive wall paintings, there is an adjoining separate diet kitchen. The chief conversation is food. There is interest and curiosity over each course. Table manners do not interfere with a full enjoyment and easy transportation of food from plate to mouth. The model is the feast in an old medieval castle.

The foods that are prepared are not made unduly attractive, and the food conglomerations (of which adults are so fond) are never served. The choice of foods that boys like is wide, and certain alleged distastes soon become nonexistent (e.g., the vegetable group, beets and spinach). (A hunger strike occurred twice during the trial week—a dramatic gesture not arising in a

distaste for food, the failure of glamor to accompany this ended each strike in three days.) There are, however, certain well established food antipathies, e.g., creamed cauliflower, tomatoes and fish.

The psychologic methods are listed:

- 1 The use of the rare dish—strawberries in January.
- 2 The establishment of an ego, which formerly has been on the basis of an odd or unusual appetite, e.g., "I haven't eaten a creamed potato for five years," to one in which the boy becomes famous as a big, nondiscriminating eater. This is especially possible with the dramatic change to a high caloric diet.
- 3 An approach through a scientific explanation. These foods have been accurately weighed and the caloric value of each is known. "It is not the food that maintains the weight,

Chart 3—Summary showing the relative values of special gaining diets. Heavy line weighed high caloric diet broken line cream and butter diet light line normal gain without special diet

(20 per cent) was given in the form of half and half (milk and cream), two glasses at each meal, and the butter was used generously on potatoes, bread and vegetables. This provided about 900 surplus calories a day and resulted in an average gain of one-seventh pound (65 Gm) daily. This rate of gaining is quite variable, some failing to respond, others increasing their weight one-half pound (226 Gm) daily (chart 2). Tables of normal gaining prepared at the school show an average monthly gain in the winter of 1½ pounds (544 Gm). This is distributed in age groups as follows: 12 years, ½ pound, 13 years, ¾ pound, 14 years, 1½ pounds, 15 years, 1¼ pounds, 16 years, 1½ pounds, 17 years, ½ pound, 18 years, ¾ pound.

that is important in gaining, but the added 1,000 calories, which will theoretically and actually cause an increase in the weight of the body." The boy considers food with an understanding of its caloric value and is familiar roughly with the calories in the common foods. This is a logic and inducement to eat which proves effective over a period of many weeks.

4 A featuring of reasons for desiring a weight gain. "It will improve you!"—a blend of vanity and ambition. A boy will often wish to gain to make football material.

5 A cultivation of the sense of taste similar to the change from a fondness for the plain music of drums to a more complicated score, to a symphony which is compared to a well balanced diet. (This argument will appeal to a boy of 11 years.)

It is to be observed that all these methods are directed at one boy, there is no group psychology, great care

is taken not to compare one boy with another or with any standard. It is purely a single-boy appeal. The diets were never explained, even to a group of two fat boys and lean and normal boys, and boys on other special diets, placed side by side, were unmindful of each other. (It is remarkable that a fat boy on 900 calories will sit next to a lean boy on 4,200 calories without comment.)

Finally, when it had been definitely established that any normal boy could be made to gain or lose significant poundage, group psychology was employed.

1 The boys were assigned to a table and told that they were on a special diet. No explanations were proffered, and the assumption was that they, like the other boys at the table would eat. This is the most simple and a very effective method.

2 Another aspect of this group reaction was the placing of a particularly overactive highly conversational boy in a tranquil corner of the diet table where the conversation was slow, the moods were level and new ideas were rare—sending them out to pasture—where thoughts sent out were driven back on themselves, and on the business of eating.

From these descriptions it appears that gaining depends not on the selection in the diet, the preparation of the food, or, particularly on the use of high calory foods but rather on the creation of the mind to eat!

CAUSES OF UNDERWRIGHT IN OLDER CHILDREN

The causes of underweight as they have appeared at the diet table and elsewhere during the past two years are as follows:

1 There is a fundamental, unexplained taste for food low in calory value, a fondness for dainty dishes and an avoidance or even repulsion to fats, e.g., a thin boy eating a chop will take only the lean portion, leaving the margin of fat. Similarly, boys having a low hemoglobin and red blood count may not by choice take foods rich in iron. For example, an apple pie containing raisins will be eaten completely except for the raisins, which are high in iron content.

2 There has been an absence of instruction and training in overcoming this changed taste in the selection of foods when it passes normal limits and produces a state of underweight.

3 Anatomic anomalies (e.g., a short small intestine) and altered absorptive and assimilative processes are theoretical causes of underweight.

4 Overactivity (in football, basket ball and track) is often a cause.

5 One chronic disease, a very important cause of underweight, is appendicitis with recurring subacute attacks.

6 There appears to be a relationship between poor posture lordosis and underweight.

OTHER OBSERVATIONS

1 The use of high calory diets in convalescence, in addition to restoring the normal weight, appears to accelerate all phases of convalescence.

2 Basal rates taken on the boys showed no relationship between the basal metabolic rate and the weight, there are no unusual readings. Pituitary substance has no influence on weight, thyroid substance was not given in order to control better this experiment in diet.

3 Among girls, food choices, eating habits and responses to diet were similar to those observed in boys. No striking dietary caprices were observed (the girls did show an inclination to omit the breakfast meal).

SUMMARY

A diet that is well balanced, prepared and served under excellent conditions and properly controlled has been carried out for several years at Cranbrook School. The actual dieting is preceded by a period of relative fasting, followed by a rapid increase in food to as high as 5,000 calories. Various devices and logic are employed to persuade the boys to eat. The selection of individuals who will show clinical improvement on a gaining diet requires, first attention to the causes of underweight and, secondly, recognition of the wide range in normal weights and understanding of the various types of body build. Individuals placed on a gaining diet who are definitely below their normal weight will show a prompt and favorable response.

Clinical Notes, Suggestions and New Instruments

AN EAR COMPLICATION FROM DINITROPHENOL MEDICATION

HENRY DINTENFASS, M.D., PHILADELPHIA

This case is presented because it demonstrates the possibility of the untoward action of dinitrophenol on the otologic apparatus in the treatment of obesity.

A M., a white woman aged 28 who weighed 150 pounds (68 Kg.), was given dinitrophenol for weight reduction in June 1933. The dose consisted of a 5 grain (0.3 Gm.) capsule of alpha-dinitrophenol administered orally once a day. Immediately following the first capsule a burning sensation at the back of the throat was experienced which lasted ten minutes. During the next few hours profuse perspiration, a dull headache and general bodily weakness occurred. At the end of four days, after 20 grains (1.3 Gm.) of the drug had been taken the symptoms increased. There was severe exhaustion accompanied by a rash over the chest and extreme dizziness and a sensation of fullness and pain in both ears.

The dinitrophenol was then discontinued, the rash cleared and the headache, weakness and dizziness disappeared. The pain and fullness of the ears however became aggravated and impairment of hearing developed. After an interval of a month during which time the ear disturbance had partly worn off the drug was again given in similar doses. There was a recurrence of the symptoms noted previously. Three days later after 15 grains (1 Gm.) of dinitrophenol had been administered it was again necessary to discontinue its use. In a week all ill effects of the drug abated with the exception of the otalgia and the impairment of hearing. There was no appreciable loss in weight at any time.

The patient was referred to me early in September 1933 two months after the discontinuance of the drug. She still complained of pain and fullness in both ears. The ear examination disclosed bulged and reddened drumheads with obliteration of landmarks on both sides and a definite diminution in hearing (about 30 per cent) catarrhal in nature. There was no doubt that this condition was brought on by congestion and inflammation of the pharynx and eustachian tubes incident to the administration of the drug. In the treatment an effort was made at first to bring relief by the use of mild antiseptic nasal sprays and gargles. No benefit however, ensued from these conservative measures. Later catheterization and bouginage of the eustachian tubes was employed and resulted in some amelioration of the symptoms.

At the present writing, February 1934, seven months after the discontinuance of the dinitrophenol although the pain and discomfort in the ears have disappeared and the redness and bulging of the drumheads have subsided there is still considerable impairment of hearing. The patient states that her hearing had always been acute prior to the use of this drug.

A QUICK EASY EFFICIENT TREATMENT OF
BARTHOLIN CYST AND ABSCESS

GODDRICH C. SCHAUFFLER, M.D., PORTLAND, ORE

Any one who has operated on a sufficient number of Bartholin cysts has found reason to dislike the routine procedure of surgical enucleation. There is often technical difficulty in complete enucleation, nearly always primary hemorrhage, frequently severe secondary hemorrhage, always postoperative discomfort, edema and relatively prolonged disability, and too frequently a recurrence.

The routine practice of simply incising and draining the abscessed Bartholin area frequently proves to be ineffectual because of recurrence of the abscess or the later development of a cyst.

I now use the technic described in the illustrations to the exclusion of any other for both abscess and cyst. I have treated sixteen cysts and ten abscesses in this manner. During an observation period varying from three months to two and one half years, I have noted no recurrence of cyst and only one recurrence of abscess.¹

As the electrode follows a spiral path outward from the center (fig 3a), the cavity lining will be seen to shrink and retract centrally, leaving at the end of the coagulating process a clean dry core of bloodless cooked cavity wall (fig 3). The

Nitrous oxide and oxygen, ethylene, or caudal block will give ideal anesthesia. Local infiltration of procaine hydrochloride is unsatisfactory.

If surgical diathermy is not available, a surgical cautery with a blunt tip heated to cherry red may be substituted.

CONCLUSION

Because of a long and frequently unpleasant experience with other methods, I am convinced that this method for the management of Bartholin cyst and abscess is in comparison highly satisfactory.

SUPERIOR MESENTERIC THROMBOSIS WITH
RECOVERY

G. J. CURRY, M.D. AND G. R. BACKUS, M.D., FLINT MICH.

A man, aged 60, a retired farmer, entered Hurley Hospital, Jan 7, 1933, because of severe epigastric pain, associated with nausea and vomiting, of sudden onset four hours before. The pain was sharp and colicky and did not radiate. The patient was apparently well and had been for a number of years up to the occurrence of the present trouble.

Fig 2—The cyst (or abscess) is opened the incision carried widely to allow complete flattening and exposure of the cavity wall by tension on the tabs of the crucial incision. The floor is carefully explored for diverticula or communicating pus sacs.

Fig 3—The pointed applicator attached to a surgical diathermy outfit is now applied to the center of the exposed lining which has been carefully sponged dry. A coagulating current with a penetration of about 2 mm is turned on and the entire lining of the cavity is destroyed by an outward spiral or snail like progression with the coagulating tip as at a. Care must be taken to cover every bit of the base of the lining including possible diverticula. A shrinkage of the cyst wall area will be noted.

Fig 5—Healing crater from seven to ten days after operation. Healing has taken place from the base by clean granulations. Very little tenderness, pain or disability.

extent of the exposed wall will have receded to about one-half its original size. Instead of a gaping hemorrhaging cavity there is a clean dry shallow pit with a solid core, which later forms a clean slough. The edges of the incision may be approximated or not. Packing is desirable to prevent premature skin closure. On subsequent visits the pit should be probed to facilitate healing from the base.

The total operative time is from five to ten minutes. The patient may go home a few hours after operation, as a rule. I have never had a hemorrhage early or late, notable postoperative infection, or edema. The postoperative course has been mild following both abscess and cyst.

Figures 1 and 4 which have been omitted from THE JOURNAL because of lack of space will appear in the author's reprints.

From the Department of Gynecology of the University of Oregon Medical School and the Multnomah County Hospital.

Presented as a clinical demonstration before the annual meeting of the Pacific Coast Society of Obstetrics and Gynecology at Portland Ore. Oct. 20, 1933.

¹ A patient developed a Bartholin abscess behind a broken down cyst four days post-partum. A secondary repair was done on the cyst, and the abscess cavity was treated rather conservatively. A cyst recurred in the Bartholin area two years later.

The remaining history was irrelevant so far as the present illness was concerned.

The patient was well developed in a state of partial collapse, and complaining of severe abdominal pain. The abdomen showed no distention, and no masses were seen or felt, tympany was present throughout, tenderness was localized to the epigastrium, and all muscles were in a boardlike spasm. All examinations were essentially negative in connection with other systems. The temperature was 100, pulse 90, respiration 24. Blood pressure was 160 systolic and 80 diastolic. Urinalysis was negative. The white blood count was 13,000, with polymorphonuclears 90 per cent, lymphocytes 10 per cent.

The entire symptomatology would lead one to associate it with the gastro intestinal tract. On the strength of these observations a diagnosis of perforated gastric or duodenal ulcer was made and the patient was prepared for immediate exploratory laparotomy.

Operation was performed under nitrous oxide anesthesia supplemented with ether, through a midline incision in the upper part of the abdomen. No perforations were found in the

From the Department of Surgery and the Department of Pathology of Hurley Hospital.

stomach or duodenum, and the gallbladder was nonpathologic. On examination of the intestine, an area of gangrene was found in the midportion of the jejunum, from 9 to 12 inches (23 to 30 cm) in length, more marked in the center and fading out at the ends. The corresponding V-shaped area marked the beginning of a much darkened area in the mesentery, for a distance of several inches. A diagnosis of mesenteric thrombosis was made and intestinal resection of about 2½ feet (76 cm) was done. This was followed by a lateral anastomosis. The abdomen was closed in layers without drainage, and the patient returned to bed in a satisfactory condition. His convalescence was uneventful and the bowels moved normally on the fifth day. The temperature, pulse and respiration remained within normal limits. The wound healed by primary union. The patient sat up on the thirteenth day and was discharged on the fifteenth.

PATHOLOGIC REPORT

Gross Examination—The specimen was a gangrenous G shaped portion of jejunum 46 cm in length, the color of which was diffuse, glossy, velvety and purplish black. At one extremity the line of demarcation from the more normal bowel

Resected jejunum showing area of infarction and gangrene. Healthy tissue may be noted at the periphery.

was sharp and distinct. The other end showed a more gradual change from gangrenous to normal. Both changes are demonstrated in the accompanying illustration. It was inelastic and doughy, the surface was friable and tore easily. The mesentery had been clipped close to the bowel and the two edges were separated from 1 to 2 cm. The enclosed vessels and adipose tissue appeared tarry, spongy and necrotic. The whole structure was filled with blood. The lumen contained thick tarry, coagulated bloody material and the mucosa would fall into the lumen with the slightest manipulation.

Microscopic Examination—Section 1. The mesentery exhibited extravasated blood throughout the adipose tissue, obscuring the fatty architecture. The veins were massively engorged and distended.

Section 2. The intestinal wall exhibited a massive widespread extravasation of blood into the wall and mucosa, causing marked distortion of the tissue. The mucosa was filled with blood and exhibited diffuse edema, maceration and sloughing.

Diagnosis—Mesenteric thrombosis with gangrene of an infarcted area.

COMMENT

This case is reported as a satisfactory result from a condition that is very serious and dramatic the results of which are ordinarily very poor, death occurring in 90 per cent of the

cases. Obstruction of the superior mesenteric artery and vein, whether by embolism or by thrombosis, produces, if of sufficient extent and suddenness, a hemorrhagic infarction of the intestine with resulting gangrene. Occlusion of inferior mesenteric vessels rarely occurs. Etiologic factors are embolism from the left heart or aorta and arteriosclerosis of the superior mesenteric artery, predisposing to roughening and thrombosis. While reestablishment of the circulation through the collaterals is possible, the usual picture is occlusion, infarction and death.

This condition is the most fatal of all abdominal emergencies. Secondary thromboses are common. The treatment is surgical, with resection of the involved intestine, such resection including a wide margin of healthy tissue.

CONCLUSION

At the present time the patient is well and healthy, with no subjective or objective complaints. According to the records investigated at Hurley Hospital for the past ten years, this is the only recovery. It is to be noted that this patient was operated on early (five hours after the onset of symptoms), which probably accounts for the favorable result.

401 Genesee Bank Building

PROPHYLAXIS OF IMPETIGO NEONATORUM

W. H. GUY, M.D. AND F. M. JACOB, M.D. PITTSBURGH

In 1928 Chadwell¹ reported three years of extraordinary success in the prevention of impetigo among the new born in a large maternity service. The method hinged on a singleunction of each infant with 5 per cent ointment of ammoniated mercury following an initial soap and water bath. On the following days sterile cottonseed oil was applied to impregnate all follicles completely with the drug. While numerous other institutions have adopted the plan we feel that the success of the method in our hands merits a report urging a more widespread adoption of this simple and inexpensive procedure.

At the Elizabeth Steel Magee Hospital there are between two and three thousand births annually. Impetigo has been present intermittently and at times in epidemic form in the nurseries since the opening of the institution. From reports and observation of other large maternity services we feel that the incidence of impetigo mentioned approximates the general experience. It is true that we have heard physicians state that in some hundreds of deliveries they have never seen examples of impetigo of the new-born. Either their experience is unique or they are not recognizing their cases. Some are diagnosing spreading bullous eruptions of the new born as pemphigus neonatorum. It must be remembered that true pemphigus of infants is an extremely rare disease and that practically all cases of this type are examples of the rather common bullous impetigo.

In 1929 there were 2,344 births in the Elizabeth Steel Magee Hospital. During 1929 thirty-four cases of impetigo were seen, the disease reaching its height during August, with twenty cases. This was the largest incidence of the disease seen for any one year. All the usual procedures of isolation and individualized treatment were carried out with meticulous care, but new cases continued to appear. Early in 1930 we instituted routine prophylactic care according to Chadwell, with a resulting prompt disappearance of impetigo from the nurseries. During 1930, with 2,363 births, two cases of impetigo were seen—one secondary to a breast abscess in the mother, and the other a questionable eruption surrounding an abscess on the scalp of the infant. During 1931, with 2,884 deliveries we saw one frank case of impetigo but in this case the prophylaxis was not given. Delivery occurred on the outside and the condition was discovered after admittance for medical attention. In 1932, with 2,522 births we saw one case of bullous impetigo for which we have no explanation. One other case was a questionable eruption surrounding an abscess

From the Department of Dermatology, University of Pittsburgh School of Medicine.
1. Chadwell, O. R. Impetigo Neonatorum: Control and Treatment, New England J. Med. 199:983-985 (Nov. 15) 1928.

on the scalp and the diagnosis was an acute infectious eczema-toid dermatitis. During 1933 no cases have been seen.

POSSIBLE DELETERIOUS EFFECTS

During the first few months after the routine prophylactic technic was begun, several cases of more or less generalized chemical dermatitis were encountered. This occurred while the 5 per cent ammoniated mercury ointment recommended by Chadwell was being used. When the ointment was reduced to a strength of 2 per cent this complication disappeared.

The urine was examined repeatedly to determine any possible kidney irritation, with negative results. Careful observation and investigation developed no contraindication for the procedure.

TECHNIC

The following is a brief outline of the technic in use at the Elizabeth Steel Magee Hospital since early in 1930.

A Delivery Room—1 As soon as possible after birth, babies are cleansed thoroughly with sterile liquid petrolatum.

2 Each baby is thoroughly rubbed from the top of the head to the soles of the feet with 2 per cent ointment of ammoniated mercury before it leaves the delivery room.

B Nursery—1 Daily cleansing is accomplished with sterile cottonseed oil.

2 The buttocks and anus are cleansed with cotton balls and cottonseed oil.

3 Soap and water and powder are not used.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
H. A. CARTER, Secretary

AN APPRECIATION

The Council on Physical Therapy takes this opportunity to express its appreciation for the valuable advice and assistance of men trained in special fields who have offered their services in the investigation of certain devices and apparatus that have been presented to the Council for consideration. For the past year the Council has received valuable assistance from Drs. Fred L. Adair, Frederick Balmer, M. Herbert Barker, H. C. Bazett, William Bierman, Walter M. Boothby, George E. Brown, E. R. Clark, John D. Ellis, Geza De Takats, F. H. Ewerhardt, Hart Fisher, Harry Goldblatt, S. Goldschmidt, K. G. Hansson, E. H. Hatton, John S. Hibben, Allan Hemingway, Disraeli Kobak, Richard Kovacs, Frank H. Krusen, Eugene Landis, Henry Laurens, C. L. Lowman, Edgar Mayer, C. O. Molander, Tell Nesson, Nathan Palmer, Earle B. Phelps, Sidney Portis, Ellison Ross, Kellogg Speed, K. W. Stenstrom, E. V. Swenson, Grant E. Ward, Prof. Fred A. Rogers, Mr. Ralph Allison and Mr. C. S. Bierwag.

REGULATIONS TO GOVERN ADVERTISING OF ULTRAVIOLET GENERATORS TO THE MEDICAL PROFESSION ONLY

Therapeutic claims in advertising matter and descriptive literature in publications intended for the medical profession are limited to conform to the following statements based on the best available evidence.

The evidence available in January 1934 indicates that ultraviolet rays have a prophylactic and curative effect on rickets, infantile tetany or spasmophilia and osteomalacia.

Prenatal irradiation of the mother and also irradiation of the nursing mother appear to have a definite and specific preventive influence on rickets. This however requires general exposure of the bare body. Mere exposure of the head and face could not be expected to yield the same result.

Irradiation may also exert a beneficial action on other disorders of calcium metabolism but the limits of such action the conditions under which it may best be produced and the specific action of the rays have not yet been fully explored.

The benefit derived by patients suffering from tuberculosis of the bones, articulations, peritoneum, intestine, larynx and lymph nodes, or from tuberculous sinuses, when the entire body is exposed to carefully graded doses of natural sunlight or of radiation emitted by certain artificial sources of ultraviolet rays, cannot be doubted. The beneficial results of such irradiation appear to be partly due to ultraviolet radiation, but it is probable that visible and infra-red rays, as well as the conditions of the atmosphere, also play a certain ill defined part in the therapeutic effect.

As far as tuberculosis of the bones and articulations is concerned the majority of those who have had extended experience with heliotherapy agree that suitable, graded exposure to natural sunlight is most effective and that exposure to artificial sources of radiation is second best. Nevertheless, under conditions that make natural heliotherapy impracticable, artificial heliotherapy has been shown to be of distinct value. Of the different types of artificial generators employed when sunlight is not available the majority of authorities express a distinct preference for the type of generator the spectral emission of which is relatively continuous and approximates most closely the solar spectrum. The same appears to be true in tuberculosis of the larynx and lymph nodes¹ whereas in tuberculosis of the peritoneum¹ and intestine a distinct preference has not been evinced.

Local exposure to ultraviolet rays of circumscribed tuberculous lesions of the urinary bladder has been shown to yield distinctly favorable results, but the method requires special applicators which are not generally available and, above all, special skill and experience in the cystoscopic diagnosis and treatment of bladder lesions.

On sluggish, indolent wounds that do not heal or that are abnormally slow in healing, local or general irradiation may have a beneficial effect. However, it is not clear that this is a specific effect of ultraviolet rays.

Exposure of the lesions of erysipelas and a wide area of surrounding tissue has been shown to have a favorable effect but whether the results of ultraviolet irradiation are superior to, or even as good as, those obtainable by proper exposure to roentgen rays has not yet been established.

Numerous claims that ultraviolet irradiation exerts a valuable therapeutic effect in secondary anemia have been advanced. The evidence supports the conclusion that while in some cases ultraviolet rays may have a slight therapeutic influence in this condition, such influence appears to be limited and, at most, irradiation is to be regarded as an adjuvant to established methods.

The notion that exposure of the body to ultraviolet rays reduces blood pressure does not receive much support from the majority of those who have had prolonged experience with natural or artificial heliotherapy. Most of them feel that, while exposure of the entire body to ultraviolet rays may induce a slight reduction in blood pressure in some individuals, such reduction cannot be depended on and, at any rate, is too slight and inconstant to be of clinical value.

Among the diseases of the skin, on lupus vulgaris alone can ultraviolet rays be said to act specifically. In other dermatoses (scrofuloderma, erythema induratum, eczema, psoriasis, pustular folliculitis, indolent ulcers, furunculosis, acne vulgaris, angioma, serpigmosum, parapsoriasis, pityriasis rosea) local or general exposure to ultraviolet radiation may have a favorable action but the improvement that may result cannot be regarded as a specific effect of the rays. In some cutaneous disorders (eczema, psoriasis, lupus erythematosus, herpes simplex, xeroderma pigmentosum, farmer's skin, prematurely senile skin) exposure to such rays may cause an exacerbation, provoke an attack, or produce other injurious effects.

Of repeated exposures to ultraviolet radiation over long periods in persons, especially children, who have a low tolerance (idiosyncrasy) to ultraviolet rays may lead to degenerative

¹ This is not intended to imply that natural or artificial heliotherapy should be used to the exclusion of other methods. In fact especially in tuberculosis of the lymph nodes and the larynx heliotherapy combined with roentgen therapy in expert hands seems to yield the best results. When tuberculosis of the lymph nodes, bones, articulations or other structures is complicated by pulmonary tuberculosis or when the tuberculous process is confined to the lungs ultraviolet irradiation must be used with caution because in some cases it may cause quiescent pulmonary foci to become active.

changes in the skin, such as atrophy, anomalies in pigmentation, keratoses and even cancer

Grossly excessive exposure of the entire body may, in certain cases cause serious illness or even death. Grossly excessive exposure to a local area may, in some cases, lead to permanent, deleterious changes in the skin.

As far as normal persons are concerned, the claim that exposure to ultraviolet rays increases or improves the tone of the tissues or of the body as a whole, stimulates metabolism or tends to prevent colds has not been conclusively substantiated.

New uses of ultraviolet and other forms of artificial radiation will be brought to the attention of the profession if and when, in the opinion of the Council on Physical Therapy, the therapeutic value of such use becomes established.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

SCARLET FEVER IMMUNITY TEST (See New and Nonofficial Remedies, 1934 p 406)

The National Drug Co., Philadelphia

Scarlet Fever Streptococcus Toxin for the Dick Test (National) (See New and Nonofficial Remedies 1934 p 406)—Also marketed in packages of one vial containing sufficient toxin for fifty tests.

TYPHOID VACCINE (See New and Nonofficial Remedies, 1934 p 398)

The National Drug Co., Philadelphia

Typhoid Paratyphoid A Vaccine (See New and Nonofficial Remedies 1934 p 401)—Also marketed in packages of thirty 1 cc ampule vials containing 750 million killed typhoid bacilli and 250 million killed paratyphoid A bacilli per cubic centimeter.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

PAUL NICHOLAS LEECH, Secretary

PULVULES AMYTAL COMPOUND (LILLY) NOT ACCEPTABLE FOR N N R

The Council recently directed the secretary to inform manufacturers of barbitol products that the Council is prepared to consider with the view of inclusion in New and Nonofficial Remedies mixtures containing barbitol (or barbitol derivative) and amidopyrine, under the descriptive name 'Tablets (name of barbitol derivative)—Amidopyrine.'

When Eli Lilly and Co. was informed of the Council's decision the firm stated that it markets a compound of amytal and amidopyrine under the name 'Pulvules Amytal Compound' and asked the Council to consider the acceptability of the name.

'Pulvules Amytal and Amidopyrine Compound' for this product. It was pointed out to the firm that this designation is contrary to the terminology adopted by the Council. As all familiar with pharmacy know, the use of the word "compound" in a title implies the presence of other constituents than those named in the title. The firm was then informed that the name 'Pulvules Amytal and Amidopyrine' would be acceptable. At one time the firm indicated acceptance of the Council's name by submitting copy for cartons and labels revised to bear the designation 'Pulvules Amytal and Amidopyrine.' However after some correspondence the firm informed the Council of its conclusion that the future of the product would be jeopardized if the name were changed. The Council therefore declared "Pulvules Amytal Compound" unacceptable for New and Nonofficial Remedies because the product is marketed under a name that is uninformative of the composition of the product.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION. RAYMOND HERTWIG, Secretary.

VAN CAMPS PURLED PEAS (ADDED SALT)

Manufacturer—Van Camp's, Inc., Indianapolis

Description—Sieved peas slightly seasoned with salt. Largely retains the natural minerals and vitamins.

Manufacture—Fresh peas, harvested at their height of development while still in the tender succulent stage, are shelled, thoroughly washed, inspected to eliminate any defective peas, and graded; the selected peas are given a minimum blanch in hot water, removed from the water and steamed in a closed kettle until soft. The softened peas, protected from air by a steam atmosphere, are sieved through a screen with openings of a size to produce the desired fineness and texture. The sieved material is adjusted with hot water to the desired consistency, salt is added, it is heated as rapidly as possible to near boiling, immediately withdrawn from the kettle again sieved, and filled into enamel lined cans, which are sealed and processed.

Vitamins—The method of preparation efficiently protects the natural vitamins.

Claims of Manufacturer—Easily digestible has a smooth consistency and supplies bulk without roughness.

QUAKER WHOLE WHEAT BISCUITS—MUFFETS CONTAINS VITAMIN D

Manufacturer—The Quaker Oats Company, Chicago

Description—Ultraviolet irradiated cooked and toasted shredded whole wheat biscuits contain 5 U S P X (Revised 1934) vitamin D units per ounce.

Manufacture—Cleaned, whole, soft wheat is cooked in a stream of continuously flowing water (99 C.), partially air dried, stored for a short period in tanks spread out in thin layers on endless belts irradiated with ultraviolet rays for a definite period to develop vitamin D effects, shredded, pressed into lacelike ribbons 1 inch wide by shredding rolls, coiled by machinery into biscuits 3 inches in diameter, toasted in a traveling oven, dried and packed in cartons.

SATURDAY, MARCH 17, 1934

THE ARGYLL ROBERTSON PUPIL

For many years the curious pupillary phenomena first described by Argyll Robertson in 1869, and which have since borne his name, were regarded as pathognomonic of syphilis of the central nervous system. More recently, descriptions of so-called Argyll Robertson pupils in other diseases have appeared frequently, thus throwing grave doubt on the pathognomonic character of the sign.

Merritt and Moore,¹ in a review of the subject, subscribe to the conclusion formulated by Adie that "the true Argyll Robertson pupil is as near as may be, in an imperfect world, an infallible sign of syphilis of the nervous system." These authors point out that confusion has arisen from two causes: first, through failure to adhere to the strict criteria of the true Argyll Robertson pupil and, second, to the lack of a clear conception of the anatomic-pathologic basis of the sign.

The Argyll Robertson pupil as originally described has five characteristics:

- 1 The retina must be sensitive to light
- 2 The pupils remain constant in size, regardless of the intensity of the illumination ("fixed pupils," owing to a break in the light-reflex arc)
- 3 They are small, though not necessarily equal in size (because of the intrinsically greater power of the constrictor pupillae muscles, therefore when both constrictor and dilator muscles are paretic, the constrictor action predominates and the pupils are more or less myotic. Myosis is a frequent though not an essential part of the Argyll Robertson sign)
- 4 They dilate imperfectly on the instillation of atropine (paresis of sympathetically innervated dilator pupillae muscles)
- 5 They contract actively on convergence accommodation (focusing the eyes for near vision is a voluntary act in which the constrictors of the pupils and ciliary muscles participate "reflexly." It is assumed on logical grounds that the pathway is from cerebral cortex to oculomotor nucleus. The lesion that produces the

Argyll Robertson pupil does not affect this pathway and consequently the pupils contract normally on accommodation)

Only one additional feature has been added to Robertson's original criteria, namely, (6) absence of dilatation of the pupils when painful stimuli are applied to the skin (absence of sympathetic ciliospinal reflex). These phenomena are obviously due to injury somewhere along the light reflex pathway (retina to third nerve nucleus to iris) and injury to the sympathetic pupillodilator fibers (midbrain to cervical sympathetic ganglions to iris). That is to say, two separate and distinct pathways of iris innervation are injured by (presumably) a single lesion. This statement cannot be emphasized too strongly, it is the crux of the matter. Failure to appreciate that the true Argyll Robertson pupil is due to a break in the light reflex arc and to an injury to sympathetic pupillodilator fibers is the cause of the rather astonishing confusion that exists in the minds of many in regard to this venerable and important sign.

Where could a single lesion be so situated that it would produce with constancy such a double injury? The exact answer to this question has had to await more perfect knowledge of the two pathways, though Kinnier Wilson in 1921, in a closely reasoned paper, arrived at a conclusion which subsequent investigation has confirmed. Largely through the experimental investigations of Karplus and Kreidl and of Randon, together with the anatomic studies of Lenz, it now seems reasonably certain that the pupillary light reflex fibers (which are probably distinct from the true visual fibers of the optic nerve) pass from the retina by way of the optic nerve, decussate partially in the chiasma, and pass backward in the optic tract to the superior colliculus, whence "part of the fibers cross in the dorsal position of the superior commissure while the remainder arch ventrally toward the oculomotor nuclei." Those light reflex fibers which decussate in the optic chiasma recross in the posterior commissure, thus affording an anatomic explanation for the occasionally observed unilateral Argyll Robertson pupil.

Beattie and his associates have shown that the nucleus of the true sympathetic center is located in the posterior part of the hypothalamus and that a portion of the fibers originating there arch ventrally to the mediolateral portion of the midbrain, thence descending uncrossed to the cervical sympathetic center. In their course from hypothalamic center to cord, the sympathetic fibers run for a short distance very close to the pupillary light reflex fibers. A lesion at this point in the midbrain (around the aqueduct of Sylvius) would affect both systems of fibers, producing the true Argyll Robertson phenomena. And Merritt and Moore state that, with the exception of a few cases of glomatous invasion of this region, "the only incontrovertible cases heretofore reported were associated with syphilis of the nervous system." This is probably too dogmatic. It is

¹ Merritt H. H. and Moore Merrill. The Argyll Robertson Pupil, Arch. Neurol. & Psychiat. 30: 357 (Aug.) 1933.

fairer to say that any lesion affecting the subependymal region of the aqueduct of Sylvius may injure the light reflex and sympathetic fibers, thus producing the Argyll Robertson pupil. The syphilitic toxin vastly predominates as an etiologic factor.

Signs that are truly pathognomonic are all too rare in medicine, those iconoclasts who attack their validity should adhere strictly to the accepted criteria of the sign. This has not been done by many who have reported reflex iridoplegia (which is only one part of the true Argyll Robertson sign) in conditions other than syphilis and tumors of the midbrain. The integrity of the Argyll Robertson pupil as a practically pathognomonic sign of syphilis seems to rest on a secure anatomic and pathologic basis.

ETIOLOGY OF MUMPS

The etiology of mumps, though investigated perhaps less thoroughly than some of the other contagious diseases, has long proved elusive. Technical difficulties of experimental investigation, combined with the infrequent availability of the earliest and probably most contagious stage of mumps, have probably delayed solution of a problem not inherently more difficult than others already solved.

Johnson and Goodpasture¹ have recently reported studies calculated to throw new light on the etiology of mumps. In their experiments, fresh saliva from six patients with epidemic parotitis was used for inoculation into monkeys (*Macacus rhesus*). In two of these instances and in two in which saliva from normal persons was used, introduction of 2 cc of saliva directly into Stenson's duct caused an immediate enlargement of the glands from volume of fluid. This was followed by a rapid and persistent return to normal in from forty-eight to ninety-six hours. In the other four monkeys the early reaction was similar but was followed six or eight days later by enlargement, tenderness, edema of the soft tissues over the glands, and fever. Preceding these local changes of the parotid gland there was an early leukocytosis followed by a progressive fall to a definite leukopenia with true and relative monocytosis, relative lymphocytosis and fall in the polymorphonuclear leukocyte percentage.

Histologic examination of the parotid glands of the monkeys at the stage of secondary inflammation revealed destructive changes in the parenchyma. The essential lesion was focal with degeneration and necrosis of a single acinus or groups of acini. In practically all cases the glands were bacteriologically sterile. Emulsions and Berkefeld filtrates prepared from the glands produced similar changes when reinjected into monkeys by way of Stenson's duct. The passage from monkey to monkey was carried through seven generations. Though the histologic changes of

the parotitis of mumps are undetermined, the lesions of the experimental disease are comparable to those found in the specific orchitis of mumps, except for the neutrophilic leukocytic response in the latter.

The Nashville observers further found that the filtrable agent in question is resistant to freezing, drying and glycerinization. Attempts to reinoculate animals previously having the experimental parotitis failed to produce any specific response. The use of convalescent serum as a means of inhibiting the action of the specific filtrable agent was inconclusive. They therefore believe that the etiologic agent in mumps is a virus and appears to be distinct from the viruses of herpes simplex and vaccinia.

The filtrability of the causative agent of mumps is in accord with the earlier work of Granata, Gordon, Wollstein and others. In view of the recent advance in knowledge of the viruses, the virus explanation seems to conform well with the known facts about the etiology of mumps, though the possibility of filtrable stages of bacteria or spirochetes cannot as yet be finally eliminated.

FORGOTTEN CALORIES

Scarcely more than a year has elapsed since the first total ablation of the normal thyroid gland for chronic heart disease of nonthyrogenous origin was performed by Berlin in December 1932.¹ Subtotal thyroidectomies had previously been undertaken, but the results in disabling heart disease proved to be disappointing. A recent commentator on the new relief procedures has remarked that heroic measures of this sort must be approached with great caution, and it is obvious that there must be a careful selection of the patients combined with great operative skill. If this method is applied indiscriminately there will be a high mortality. Almost equally important is a clear understanding of the metabolic factors that are involved, in fact, they represent the crux of the matter. Du Bois² has noted that the whole problem of management of heart disease seems to depend on the relationship of the demands of the total metabolism and the needed cardiac output with the capacity of the organism to meet these demands. The total metabolism must be adjusted in the best manner to the changing efficiency of the circulation.

In recent years there has been a rapidly growing appreciation of what is termed the basal metabolism or basal metabolic rate. Physicians have become accustomed to the frequent measurement of the expenditure of energy at complete rest. They understand, as F. G. Benedict, pioneer investigator in this field, has expressed it, that the body is a living machine which is obliged to expend a measure of energy simply in keeping alive.

¹ Johnson, C. D. and Goodpasture, E. W. *Etiology of Mumps*. J. Amer. Med. Soc. 59:1 (Jan.) 1934.

² The details are given by Friedman, H. I. and Blumgart, H. I. *Treatment of Chronic Heart Disease by Lowering the Metabolic Rate*. J. A. M. A. 102:17 (Jan. 6) 1934. The literature of the subject is recorded in this paper.

² Du Bois, E. F. *Total Exchange in Relation to Clinical Medicine*. Bull. New York Acad. Med. 9:680 (Dec.) 1933.

The heart, for example, never pauses in its task of maintaining a head of pressure in the blood conduits of the body.³ The respiratory mechanism is constantly supplying the oxygen that is needed and removing the useless and harmful products of combustion. The thermostatic devices by which the temperature of the body is regulated and held constant are always functioning. The white corpuscles of the blood, "scavenger cells" so called, are forever wandering about, ameba fashion, searching for infected tissues and clearing them of bacteria. Then whether one is asleep or awake, glands are secreting their products, visceral muscles are rhythmically contracting, the nervous system, the master tissue that controls all the functions of the body, is being kept "in tone."

Du Bois has lately pointed out that physicians have perhaps concentrated too much on the basal metabolism and have neglected the total. The basal metabolism is important in diagnosis, but basal conditions are found during only a small fraction of the day, usually only four or five hours out of the twenty-four. The stimulating effect of food, the so-called specific dynamic action, is measurable, though not of major importance. Richardson and Mason⁴ were able to reduce the stimulating effect of food to as low as 2.6 per cent by giving small meals at frequent intervals, thus supplying to the body the foodstuffs at just the rate at which they were being metabolized. The most important elevating factor is muscular exercise. It is this that the physician is more likely to underestimate. An illustration of the mounting "cost of work" is afforded by some of Benedict's observations on women. When they were standing, their metabolism was 9 per cent above the basal, simple sewing increased heat production 13 per cent, dusting 134 per cent, sweeping 150 per cent. He found that when a woman climbed an average flight of stairs she expended two calories. For the same expenditure of energy she could walk down three flights of stairs or could walk about 45 yards on the level. Du Bois has well stated the problem as it should appeal to the physician. From the clinical standpoint, he remarks, the basal metabolism must be considered as a plateau of expenditure on which are superimposed wavelike increases from the specific dynamic action of food and sharp peaks from muscular exercise. Fortunately, he adds, the body does not have to pay its caloric debts for severe muscular exercise immediately but distributes the load over a period of recovery. Fear and apprehension may so increase the cost of work that a given muscular task which would require only one calory from a normal person would require several calories from the patient. Forgotten calories have come into the foreground of interest again through the modern necessities of controlling metabolism.

HEALTH IN THE ARMY

When the progress of medicine as a whole is surveyed, certain broad questions naturally present themselves. What success has been attained in controlling important infectious diseases? How are the advent and adoption of advances in technique reflected in more favorable vital statistics? Do modern modes of transportation increase the danger to life in the population? An approach to these and other questions is afforded by the data contained in the Annual Report of the Surgeon General to the Secretary of War. In view of the accuracy of the statistics made possible by the army organization, the observations are of particular value. The average daily strength of the army, not including nurses, was 131,925 for the year ended June 30, 1933. During this interval the loss in time due to sickness and injury was 1,471,147 days. Although venereal diseases are definitely decreasing as a cause of loss of time and the rate in 1932-1933 was the lowest in army history, gonorrhea heads the list and syphilis is third in the list of causes of loss of time in the past year. Tuberculosis was second in importance and influenza fourth. External injuries, notably those connected with automobiles, are accounting for an increasing amount of loss of time.

There has been a marked reduction in the death rate exclusive of battle injuries in the army during the last thirty-five years, and in the last hundred years the rate has been reduced 88 per cent. The rate in 1932-1933 was 4.27 per thousand. It is more or less surprising that during the past year, as in the two preceding years, automobiles accounted for the largest number of deaths among officers and enlisted men. In 1932-1933, deaths from external causes exceeded those from all classes of diseases combined, there were more suicides than in any of the last five years. During 1932-1933, influenza accounted for the largest number of admissions to hospitals, with bronchitis next and athletic exercises third. It is of especial interest that during the years 1853 to 1862 489 of each thousand admissions were for treatment of the gastro-intestinal group of diseases, whereas in the last ten years the rate from this particular cause has fallen to 2.9. The rate of discharge from the service for disability was much lower than usual. A review of the causes for discharge shows that more than a third were in the group of nervous and mental diseases, with dementia præcox conspicuous.

The total regular army represents in numbers the population of a fairly large city. However, it is a young and healthy group, on which as a result of military discipline there have been imposed restrictions resulting in more or less regular and uniform habits of life. Furthermore, attention to sanitation and nutrition in the light of modern concepts has produced environmental conditions conducive to good health. It should represent, in general, the optimum of health that can be produced in large groups under especially favorable circumstances.

Current Comment

"GROWING PAINS"

Who among the older practitioners of medicine is not familiar with the expression "growing pains"? These words offered solace to disturbed parents, they supplied a comforting subterfuge for the confused physician, they presented a challenge to the thoughtful investigator. It is said that the expression was coined about a century ago by Duchamp, who observed that a large number of children during puberty suffer from various muscular aches and pains. "Growing pains" thus became the synonym most commonly used for designating vague recurrent, afebrile muscular pains. The theory that growth actually is responsible for pains was by no means the mere figment of obscure observers. It was championed by representative writers. Even as late as 1908 the distinguished psychologist G. Stanley Hall wrote in his widely read book on adolescence:

There are two kinds of so-called growing pains: first that located in the epiphyses and growing centers of the bones which are supplied with nerves and may become the seats of inflammation. These pains may seem seated in the bones, limbs and perhaps most often near the neck of the femur and the tibia, although almost no part of the body is entirely exempt from them. Adolescent tarsalgia and arthralgia have been described. The rapid bone growth following fever may be attended with painful though mild osteitis, periostitis, especially in boys between 11 and 22. Secondly, the bones may grow faster than the muscles or the skin, the latter then suffer from abnormal tension and are stretched and perhaps bloodless, especially in the thighs. This too is often acutely painful.

After all, the standing of "growing pains" is not widely different from that of the more formal expressions "myalgia," "fibrositis," "myositis," "myofibrositis," "rheumatische schwiele," "lumbago" and "neuralgia." In an elaborate review of the subject, Seham and Hilbert¹ have pointed out that in this country the pioneer Jacobi gave the theory of growing pains the strongest blow when in 1884, he announced that these vague, ambiguous pains in children are probably associated with rheumatism. He clearly saw the clinical relationship between growing pains and articular rheumatism and even endocarditis. He noted that uncomplicated muscular rheumatism is rare in young children and at that time he wrote: "'Growing pains' are not infrequently inflammatory rheumatism, and endocarditis of later years may be traced back to the growing pains which are but dimly remembered." There is no real evidence to substantiate the old idea that normal growth causes chronic muscular pains. There is timeliness in the contention of Seham and Hilbert that the term growing pains is a misnomer and should be discarded. Chronic pains in the muscles which can be differentiated from chronic fatigue and definite orthopedic disorders are probably the result of a chronic infection. Many of the muscular pains may properly be classified as the muscular rheumatism of childhood.

Association News

MEDICAL BROADCASTS

National Broadcasting Company

The American Medical Association broadcasts on a coast-to-coast network each Monday afternoon from 4 to 4:15, Central standard time (5 o'clock Eastern standard time, 3 o'clock Mountain standard time and 2 o'clock Pacific standard time). The next three broadcasts will be as follows:

March 19 Mechanization of Medicine Morris Fishbein M.D.
March 26 Why Pasteurize? W. W. Bauer M.D.
April 2 What Is Health? W. W. Bauer M.D.

Columbia Broadcasting System

The Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, Central standard time. The next three broadcasts will be as follows:

March 22 Progress of Surgery Morris Fishbein M.D.
March 29 Flowers That Bloom in the Spring W. W. Bauer, M.D.
April 5 Smog, W. W. Bauer M.D.

THE CLEVELAND SESSION

Annual Tournament of the American Medical Golfing Association

The American Medical Golfing Association will hold its twentieth annual tournament at the Mayfield Country Club in Cleveland on Monday, June 11.

Thirty-six holes of golf will be played in competition for the fifty trophies and prizes in the eight events. The trophies include the Association Championship for thirty-six holes gross, the Association Handicap Championship for thirty-six holes net, the Choice Score Handicap Championship for thirty-six holes gross, the low gross Eighteen Hole Championship, the low net Eighteen Hole Handicap Championship, the Maturity Event limited to Fellows over 60 years of age, the Oldguard Championship limited to competition of past presidents, and the Kickers Handicap. Other prizes and events will be announced at the first tee.

Dr. Homer K. Nicoll of Chicago is president and Dr. Charles Lukens of Toledo and Dr. John W. Powers of Milwaukee are vice presidents of the American Medical Golfing Association which was organized in 1915 by Dr. Will Walter, Dr. Wendell Phillips and Dr. Gene Lewis. The living past presidents include Dr. Wendell Phillips of New York, Dr. Thomas Hubbard of Toledo, Dr. Fred Bailey of St. Louis, Dr. Edward Martin of Philadelphia, Dr. Robert Moss of San Antonio, Dr. Charlton Wallace of New York, Dr. Will Walter of Charlottesville, Va., Dr. James Eaves of San Francisco, Dr. Chester Brown of Danbury, Conn., Dr. Samuel Childs of Denver, Dr. W. D. Shelden of Rochester, Minn., Dr. Walter Schaller of San Francisco, Dr. Edwin Zabriske of New York, Dr. Frank Kelley of Detroit and Dr. John Welsh Croskey, Philadelphia.

The Cleveland Committee is under the chairmanship of Dr. John B. Morgan, 1301 Medical Arts Building, Cleveland, Ohio. He will be assisted by Drs. R. H. Birge, A. V. Bosen, E. F. Freedman, F. T. Gallagher, Secord Large, E. P. McNamee, J. J. Marek, Theodore Miller, U. V. Portman and M. A. Thomas.

The Mayfield Country Club of Cleveland is described by Dr. Morgan as "probably the finest course in the district, and certainly one of the most interesting. Many championships have been held on this course," he says, "and I am sure the visiting doctors will be delighted with it in every sense of the word. This country club has a most beautiful club house."

APPLICATION FOR MEMBERSHIP

Membership in the A. M. G. A. is open to any male Fellow of the American Medical Association. Write the Executive Secretary, Bill Burns, 4421 Woodward Avenue, Detroit, for an application blank. Participants in the A. M. G. A. tourna-

ment are required to furnish their home club handicap, signed by the secretary. No handicap over 25 is allowed.

The twentieth tournament of the American Medical Golfing Association promises to be a gay affair, attended by some two hundred medical golfers from all parts of the United States.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Society News—The Tuscaloosa County Medical Society was addressed in March by Drs. Lloyd Noland, Fairfield, on surgical aspects of amebiasis, and Groesbeck F. Walsh, Fairfield, pneumonia and massive atelectasis. The society was addressed in February by Drs. Marye Y. Dabney and Gilbert F. Douglas, Birmingham, on lesions of the breast and pelvic infections in the female, respectively.

Health and Reemployment Projects—A malaria blood index of school children in fourteen counties will be inaugurated by the state department of health in cooperation with the U. S. Public Health Service, to serve as a base line for measuring the results of several malaria control projects. Five thousand examinations will be made; it is anticipated and will form a scientific base for measuring the future incidence of malaria in Alabama. Other health projects, undertaken as a part of the federal government's plan for reemployment, are community and school sanitation, the closing of abandoned mines, ecto-parasite surveys in three areas, and a rat extermination campaign in twenty-one counties. The latter two projects are aimed at the control of typhus fever, which has shown an alarming increase during the past two years; it was stated. The reduction of illness and deaths from intestinal conditions is the factor in the sanitation program, while the sealing of abandoned mines is intended to protect public water supplies. This can be accomplished by preventing chemical action so that the acid wastes will not enter streams used or available for use as public water supplies.

COLORADO

Society News—The Medical Society of the City and County of Denver devoted its meeting, February 20, to a presentation of case reports: probable cirrhosis of the liver, Dr. Thomas D. Cunningham, syphilis, Dr. Osgood S. Philpott, carcinoma of the breast, Dr. Frank E. Rogers, and cicatricial ectropion, Dr. William M. Bane. Dr. Henry F. Helmholz, Rochester, Minn., addressed the El Paso County Medical Society, February 7, in El Paso, on "Convulsive Seizures in Children." At a meeting of the Larimer County Medical Society in Fort Collins, February 7, Dr. Gerrit Heusinkveld, Denver, discussed "The Disorders of Menstruation." Speakers before the Northwestern Colorado Medical Society at Steamboat Springs, January 25, were Drs. Maurice H. Rees and Philip Work, Denver, on "Modern Medical Education" and "Diagnosis and Treatment of Head Injuries from the Neurological Point of View," respectively. A symposium on normal physiology of the gastro-intestinal tract constituted the meeting of the Pueblo County Medical Society in February; the speakers were Drs. George W. Bancroft, Colorado Springs, and Josephine N. Dunlop and George A. Unfug, Pueblo. A symposium on exophthalmic goiter constituted the meeting of the Boulder County Medical Society in Longmont, February 8, with Drs. Jack D. Bartholomew, Louisville, John D. Gillaspie, Harry A. Alexander and Claude D. Bonham as speakers.

CONNECTICUT

Personal—Dr. Harvey Cushing, Sterling professor of neurology, Yale University School of Medicine, New Haven, was recently elected president of the History of Science Society.

Health in Connecticut—The lowest birth rate (134 per thousand of population) ever recorded in the state was reached in 1933, according to provisional figures of the state health department. A new low rate was also obtained for tuberculosis, 47.2 per hundred thousand. The general death rate was 10.1 per thousand, the same rate recorded in 1932. The rate

reached in 1932 for infant mortality was also recorded in 1933, 48.2 per thousand live births.

Alumni Day—A general meeting was a feature of the exercises on Alumni Day at Yale University School of Medicine, New Haven, February 22, with the following speakers:

George H. Smith, Ph.D., professor of immunology, The Place of the Yale Journal of Biology and Medicine in the Educational Program of the School of Medicine.

Dr. Joannes Gregorius Dussier de Barenne, Sterling professor of physiology, Some Studies on the Junction of the Layers of the Motor Cortex.

Edgar Allen, Ph.D., professor of anatomy, The Life Span of Reproductive Cells.

Walter R. Miles, Ph.D., professor of psychology, Psychology in Relation to Medicine.

DISTRICT OF COLUMBIA

Major General Gilchrist Honored—Fifty members of the medical corps gave a luncheon at the Army and Navy Club, January 31, in honor of Major General Harry L. Gilchrist, former chief of the chemical warfare service of the U. S. Army, on the occasion of his retirement. Major General Robert L. Patterson, surgeon general of the army, reviewed the career of General Gilchrist, who was in charge of the first unit to join the American Expeditionary Forces in France in the World War.

Society News—The Medical Society of the District of Columbia was addressed March 14, by Dr. Prentiss Willson, president, on "Medievalism in Modern Medicine." Speakers before the Washington Medical and Surgical Society in January were Drs. Cyril Burbank and Boyce R. Bolton on blood pressure and hemolytic streptococcal meningitis with recovery, respectively. Dr. William C. White has been reelected president of the District of Columbia Tuberculosis Association.

GEORGIA

Graduate Lectures—Dr. Richard Schatzski, Leipzig, Germany, delivered a five-day series of lectures before the Fulton County Medical Society, Atlanta, beginning February 5. This was the society's first presentation of graduate lectures. Dr. Schatzski lectured on "The Relief Method of Examination in Gastro-Intestinal Tract Disease" and conducted clinics demonstrating particularly the relief method under fluoroscopic examination on live subjects.

Portrait of Dr. Block—A portrait of Dr. E. Bates Block, late professor of neurology and psychiatry, was presented to Emory University School of Medicine, Atlanta, February 9. Dr. Charles N. B. Camac made the presentation address on Dr. Block's life work and influence, and Julia Lowry Block and Bates Block, Jr., unveiled the portrait. Dr. Russell H. Oppenheimer accepted the portrait on behalf of the medical school. Other speakers included Dr. Lewis M. Gaines, I. Sprole, Lyons, LL.D., and Dr. Richard B. Wilson. Dr. Block died Oct. 25, 1932.

Typhus Fever Control—A concentrated program for the control of typhus fever has been inaugurated in Georgia. This disease is now recognized as one of the major public health problems of the state, having increased from forty-eight cases in 1928 to 618 in 1933. It is pointed out that the disease is not only increasing but rapidly spreading. Mobile units for typhus control are now being organized as a part of the program, the foci of infection to be determined through epidemiologic study. A program of trapping and poisoning with red squill in seventy-one counties in southern Georgia, where the disease is most prevalent, is under way by the Biological Survey and the U. S. Public Health Service, and the state department of health are cooperating in rodent and ectoparasite surveys of rats in Savannah, Brunswick and Atlanta.

ILLINOIS

Cases of Amebiasis—One hundred and seventeen cases of amebiasis were reported in Illinois during the first seven weeks of 1934, according to the state health department.

Personal—Dr. James C. Stewart has resigned as managing officer of the Alton State Hospital and Dr. Dudley T. Dawson, Danville, has been named to succeed him. Dr. Robert E. Miltenberger has been appointed health officer of Spring Valley, succeeding the late Dr. Frank B. Schurtz. Dr. Frank A. Stubblefield, for twenty years superintendent of the Chester State Hospital, Menard, has resigned, and Dr. James M. McManus, Cairo, has been named acting manager to succeed him.

Health in Illinois—A mortality rate of 10.5 per thousand population was reached for the state in 1933, according to final

provisional figures from the state department of health. This is a slight decrease over the rate for the previous year, 107. The infant mortality rate for the year was 506 deaths per thousand births as compared with 52 per thousand in 1932. With 104,587 births for the year, the rate was 134 per thousand as against 144 in 1932. The maternal mortality rate was 54 deaths as compared with 52 in 1932. This is attributed to the unusually low birth rate rather than to the greater loss of mothers. New low figures were also attained for diphtheria with 134 deaths, typhoid, 111, and tuberculosis, 4,173.

Chicago

University News—Dr Max Cutler addressed the faculty and students of the University of Illinois College of Medicine, February 28 on "Radium—Its Physical Properties, Biological Aspects and Uses in the Treatment of Cancer."

Society News—At a meeting of the Chicago Orthopedic Club, March 9 Dr Stanton K. Livingston among others spoke on "Bony Changes Due to Parathyroid Disease." Speakers at the meeting of the club, February 16 included Drs Jerome T. Jerome on "Tuberculous Spines in Young Children" and Cly H. Hatcher, "Longitudinal Growth of Bone and Rate of Growth from Various Epiphyses." Speakers before the Chicago Pathological Society, March 12, included Drs Francis D. Gunn and Walter H. Nadler on "Osteomalacia in the Male."—Dr Carlo S. Scuderi, among others spoke before a joint meeting of the Institute of Traumatic Surgery and the Chicago Roentgen Society, March 8, his subject was "Ambulatory Treatment of Fractures of the Spine."—Speakers before the Chicago Neurological Society, March 15 were Drs Charles N. Pease, on "Injuries to the Vertebrae and Intervertebral Disks Following Lumbar Punctures," Harry A. Paskind, "Parosmia in Tumorous Involvement of the Olfactory Bulbs," and Paul M. Levin "Neurological Symptoms of Uveoparotid Fever."—Dr Florimond J. LeBlanc, Elgin, Ill., addressed the McDonagh Society for Clinical Research, March 16 on "Constitution as a Guide in Therapy."—Among others, Dr Elias Selinger spoke before the Chicago Ophthalmological Society, March 19, on "Studies in Albumin Content of the Aqueous."—Dr Lathan A. Crandall, among others, will speak before the Chicago Society of Allergy, March 19, on "Recent Developments in the Migraine Problem."—The Chicago Pediatric Society will be addressed, among others, March 20 by Dr Robert A. Black on "The Management of the Rheumatic Child."

KANSAS

Society News—Dr Edward R. Hays, Falls City, Neb., discussed "Economic Changes in the Practice of Medicine" before the Brown County Medical Society, January 19, and Mr E. S. Parsons, manager of the Pioneer Service Company, Hiawatha, spoke on "The Doctor and Collections."—At a meeting of the Butler-Greenwood County Medical Society in Eureka, January 12, a professional council of the promotion of public health was inaugurated in an attempt to combine medicine, dentistry and pharmacy for the consideration of problems common to the allied professions. C. A. Northcutt, D.D.S., Ponca City, Oklahoma, addressed the meeting on "The Interrelationship of Dentistry and Medicine."—Dr William H. Algie spoke on tularemia before the Clay County Medical Society in Clay Center, January 10 and Dr Warren R. Morton Green, a paper on "Pain Simulating Angina Pectoris."—The Harvey County Medical Society was addressed January 8 by Drs Alfred S. Hawke and James A. Wheeler, both of Newton who discussed placenta praevia and the Cope land bill, respectively.—Dr Henry N. Tihen, Wichita, discussed medical practice in Europe and Old Grecian History" before the Shawnee County Medical Society, January 8.—At a meeting of the Washington County Medical Society in Greenleaf, January 9 Drs Z. Hosea Snyder and Lynn J. L'Ecuyer, Greenleaf spoke on "Seminal Vesicle Troubles" and Sinuses.—Their Location and Drainage," respectively.

KENTUCKY

Bill Introduced—H. 750 proposes to require both parties to a prospective marriage as a condition precedent to obtaining a license to marry to present certificates from physicians, made within ten days from the date of application for a license, showing that both parties are free from contagious or infectious venereal disease, tuberculosis, hereditary insanity, feeble-mindedness or epilepsy.

Eyesight Swindlers—A physician of Russellville has recently reported the appearance of eyesight swindlers in Logan County, using methods that are familiar in reports from other

states. A pair of representatives of "Dr Miles, C. cord and Grove Avenues, Chicago"—there is no such person nor any such place—approach a man of some means whose vision is impaired. They propose to treat his eyes and collect large sums of money (\$300 in two cases) with a promise to refund it if the patient is not cured within a specified time. Some time later another pair comes along, informing the victim that the first "doctor" has been killed in an automobile accident. They then offer to rent him a "radium belt" to complete the treatment of his eyes. This belt is so valuable that it is not for sale and in order to guarantee its safe return the fakers induce the victim to give them a negotiable bond (in one instance \$1,000) which they cash promptly. During the early part of February, two men making the second visit were arrested when they appeared, a friend of the victim having notified the sheriff. One giving the name E. J. Mandell or Mendell and the address 1417 Grand Avenue, Chicago, was about 45 years old, 5 feet 4 inches tall, weighed 158 pounds and wore glasses. The other gave the name S. Bernstein, was 40 years old and weighed 175 pounds. For want of proof they were released on condition that they would refund the \$300 in this case. Through the tracing of their telephone calls, it was found that the money was wired to them by a man in New Orleans who gave the name Greenburg.

LOUISIANA

Gift to Touro Infirmary—As a memorial to his wife, Augustine Mr. Lazare Bloch, New Orleans, donated \$200,000 to Touro Infirmary to reconstruct the public wards and to establish a memorial fund, the income of which will be used to broaden the institution's charitable work. The gift also makes possible the construction of a new building.

Society News—Dr Theodore Diller, Pittsburgh, addressed the annual installation meeting of the Orleans Parish Medical Society, January 8, on "Human Credulity as Illustrated by Witchcraft." Dr Waldemar R. Metz is now president. Dr Kendall Emerson, New York, spoke before the society, January 22 on "Relationship Between the General Practitioner and the Tuberculosis Movement."—The Seventh District Medical Society was addressed in Crowley, December 14, among others, by Drs Daniel N. Silverman and Roy E. Delahoussaye, New Orleans, on diagnosis and treatment of certain forms of dysentery and the thymus gland, respectively.—The Acyelles Parish Medical Society observed "President's night," March 14, in Cottonport. Dr Albert M. Abramson, Marksville, was the speaker.

MAINE

Society News—The Portland Medical Club was addressed in Portland, January 2, by Dr Eugene H. Drake on "Paroxysmal Tachycardia."—At a meeting of the Hancock County Medical Society in Ellsworth, Dec. 13, 1933, Dr Harold E. Pressey, Bangor, discussed "Common Skin Affections," and Henry C. Knowlton, Bangor, "Use of Insulin in Malnutrition in Nondiabetics."—The Kennebec County Medical Association devoted its meeting, January 18, to a discussion of cancer and tumors.—Speakers before the York County Medical Society in Kennebunk, January 10, were Drs Gilbert E. Haggart, Boston, on "Treatment of Fractures of Both Bones of the Legs," and Harry Archibald Nissen, Boston, arthritis.

MARYLAND

Society News—A symposium on tumors of the bronchi and lungs was presented before the Baltimore City Medical Society, January 19 by Drs Charles R. Austrian, Edwin N. Broyles, John W. Pierson and William F. Rienhoff.—Medical problems incident to the depression were discussed at a meeting of the Baltimore County Medical Association in Baltimore, January 17, by Drs Arthur J. Lomas, Huntington, Williams, George H. Preston and Grace Baker.

Dr Frost Retires as Dean—Dr Freeman Appointed.—The retirement of Dr. Wade Hampton Frost as dean of Johns Hopkins School of Hygiene and Public Health, effective in July when his term expires, is announced in the *New York Times*, March 11. Dr. Allen Weir Freeman, professor of public health administration at the school since 1923, has been named to succeed him. Dr. Frost who is 54 years of age, was born in Marshall, Va. He received his degree of doctor of medicine at the University of Virginia in 1903. From 1905 to 1929 he was associated with the U. S. Public Health Service. From 1919 to 1921 he was resident lecturer in epidemiology at the school of hygiene and public health since which time he has been professor. He was appointed dean in 1931. Dr. Frost

plans to devote his entire time to his duties as professor of epidemiology. Born in Virginia in 1881, Dr. Freeman graduated in medicine at Johns Hopkins University School of Medicine. During his career he has been medical inspector of the Richmond Health Department, epidemiologist with the U. S. Public Health Service and state health commissioner of Ohio, a position he resigned in 1921 to go to Johns Hopkins School of Hygiene and Public Health as resident lecturer in public health administration. He was appointed professor in 1923.

MASSACHUSETTS

Bill Introduced—S. 252 proposes to authorize the commissioner of insurance to require an insurance company to pay such fees as the commissioner deems proper to a physician who has treated a person injured by an automobile to the owner of which the company has issued a public liability policy.

MICHIGAN

Campaign Against Marijuana Cigaretts—The Wayne County Medical Society is cooperating in a campaign against the sale of marijuana cigarettes to Detroit children between the ages of 15 and 20. Dr. Don W. Gudakunst, director of the school health service of the Detroit Health Department and chairman of the narcotic committee of the medical society, called a special meeting to decide what action the society would take. More than 100 peddlers are said to be selling these cigarettes in Detroit.

Society News—Dr. William J. Stapleton, Jr., Detroit, will address the Bay County Medical Society in Bay City, March 28, on malpractice. The women's auxiliary of the Wayne County Medical Society held an art exhibit in the society's headquarters, March 11-15. At the society's "Past Presidents' Night," February 12, the guests of honor were Drs. Oscar S. Armstrong, 1892-1893, the oldest living past president; James E. Davis, 1921-1922, and James H. Dempster, 1926-1927. Dr. Louis J. Hirschman, Detroit, addressed the Oakland County Medical Society, February 21, on "The Physician Looks at the Orient." As a part of the national child health recovery program, a survey of the nutritional status is being conducted in Oakland County. The Detroit Bar Association will hold a joint meeting with the Wayne County Medical Society, March 19. In addition to a talk by Judge Robert Toms of the circuit court, a symposium on appendicitis will be presented by Drs. Louis J. Morand, William J. Cassidy, and Angus McLean. The annual meeting of the Northern Tri-State Medical Society (Michigan, Indiana, Ohio) will be held at the Hurley Hospital, Flint, April 10. Included among the speakers will be:

- Dr. Carl A. Hedblom, Chicago, Selective Surgical Treatment of Pulmonary Tuberculosis
- Dr. Clifford G. Grulee, Chicago, Some Interesting Conditions in Newly Born Infants
- Dr. George C. Hale, London, Ont., Sleep
- Dr. Frank Smithies, Chicago, Regional Infectious Ulcerative Colitis
- Dr. Herman L. Kretschmer, Chicago, Changing Trends in the Treatment of Prostatic Obstructions
- Dr. Wilder Groves Penfield, Montreal, Canada, Epilepsy: Classification and Management of Cases
- Dr. Frank H. Lahey, Boston, will deliver the banquet address on "Management of Gout."

MISSISSIPPI

Bills Introduced—S. 366 proposes to grant to physicians, hospitals or nurses treating persons injured through the fault of other persons, liens on all rights of action, claims, judgments, settlements or compromises accruing to the injured persons by reason of their injuries. H. 603, to supplement the dental practice act, proposes to make it unlawful for dentists to use handbills, posters, circulars and other advertising devices and means other than such professional cards or announcements as are permitted in the bill.

NEW JERSEY

Health at Trenton—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended March 3, indicate that the highest mortality rate (23.4) appears for Trenton and the rate for the group of cities as a whole 12.8. The mortality rate for Trenton for the corresponding week of 1933 was 15.1 and for the group of cities 11.5. The annual rate for eighty-six cities for the nine weeks of 1934 was 12.7, as against a rate of 12.5 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that

some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Society News—Dr. Louis H. Clerf, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, February 9, on "Diagnosis and Treatment of Bronchiectasis." A symposium on treatment of pneumonia was presented before the Passaic County Medical Society, Paterson, January 11, by Drs. Charles J. Murn and Louis G. Shapiro. Dr. David W. Kramer, Philadelphia, addressed the Gloucester County Medical Society, Pitman, January 18, on "Diseases of the Arteries and How to Recognize Them." Dr. Richard D. Freeman, South Orange, was recently elected president of the Society of Surgeons of New Jersey. Dr. Clay Ray Murray, New York, among others, addressed the Bergen County Medical Society, January 9, on fractures. Dr. Arthur M. Fishberg, New York, addressed the society, February 13, on hypertension and allied conditions. Dr. William H. Ross, Brentwood, N. Y., addressed the Essex County Medical Society, Newark, January 11, on "Medicine and a Health Conscious Public." A symposium on diseases of the biliary tract was presented by members of the staff of St. Francis Hospital, Jersey City, at the meeting of the Hudson County Medical Society, February 6, as follows: Drs. James F. Norton, Thomas J. White, Earl J. Halligan, William Wallace Mayer and Frank J. McLoughlin.

NEW YORK

Annual Hobby Show—Physicians of Rochester held their second annual hobby show in January at the Rochester Academy of Medicine, opening with an address on "Art in Medicine" by Dr. Robert Tait McKenzie, Philadelphia, well known as a sculptor. Among the exhibitors were Drs. Edward Parrell who displayed wood carvings, Stearns S. Bullen, hammered copper, Clarence P. Thomas and Elmer J. Wendel, ship models, Gilbert H. Welch, bows and arrows, John R. Wilkins and Henry B. Crawford, crayon sketches, Istvan Gaspar, oil paintings, Joseph R. Mayer, collection of pistols, Eldred W. Kennedy, stamps, and Roy W. Kimball, geological specimens.

Bills Introduced—S. 1084 to amend the medical practice act proposes to define the practice of medicine so as to include the administration of anesthetics. It is not to apply to licensed dentists who administer anesthetics in connection with the practice of dentistry. A. 1268 proposes to make it unlawful for any person willfully and by or through any false statement to ask for assistance from any physician or hospital. A. 1304 to amend the medical practice act proposes to make it unlawful for any one other than a licensed physician to conduct direct supervise or control the work or reports of a clinical laboratory. The bill defines a 'clinical laboratory' as a 'laboratory in which tests are made on individual persons, their secretions, excretions, blood and tissues to aid in the diagnosis, prognosis or treatment of the individual's physical or mental state or states.' A. 1377 proposes to prohibit a corporation from using the word 'Doctor' or 'Dr.' as a part of its corporate name. A. 1513 proposes to require every person who compounds or manufactures any drug, medicine, chemical, dental, pharmaceutical or cosmetic preparation to register with the state department of health as a condition precedent to his right to sell his product the exact proportions of all ingredients used in it. The department is authorized to refuse to grant registration to any applicant whose compound or preparation it deems deleterious or injurious to public health.

New York City

Summer Course on Tumors—Columbia University announces that Dr. William H. Woglom will give a course in the pathology and diagnosis of tumors at the Institute of Cancer Research in connection with the summer session. The course will begin in July and last six weeks. The fee will be \$37.

Academy Meetings—The New York Academy of Medicine in cooperation with the Society for Experimental Biology and Medicine presented a symposium on 'The Present Status of the Rheumatic Fever Problem' at a joint meeting, February 1, with the following speakers: Drs. William C. Von Glahn, Thomas Duckett Jones, Boston, and Homer F. Swift, March 1, the meeting of the academy was devoted to a symposium on 'The Problem of Cavitation in Pulmonary Tuberculosis,' with the following speakers: Drs. Edward S. Welles, Edgar Mayer, Saranac Lake, and Ross Golden.

Personal—Dr. Ernest H. Gruening, a graduate of Harvard University Medical School, has been appointed editor of the New York *Evening Post*. Dr. Gruening went into newspaper work immediately after graduation. Dr. Francis Carter

Wood, director of the Institute for Cancer Research, Columbia University, has been made an honorary member of the Norwegian Society for Medical Radiology.—Dr Samuel Weiss has been elected a corresponding member of the Society of Gastro-Enterology of Paris.—Dr William H Best has been appointed deputy commissioner of health he has been associated with the health department for eighteen years.—Dr Walter R Loewe was recently elected president of the Tufts Medical Club of New York, and Dr Maurice Coleman Harris, secretary.—Dr George Gray Ward, Jr., was recently made an honorary fellow of the Edinburgh Obstetrical Society

OHIO

State Board Officers Elected—Dr J Fred Wurst, Dayton, was elected president of the Ohio State Medical Board at a meeting in January. Drs James G Blower, Akron, and Floyd S Meek, Cleveland, were elected vice president and treasurer, respectively, and Dr Herbert M Platter, Columbus, reelected secretary

Honorary Degrees—At the centennial celebration of Ohio State University College of Medicine in Columbus, March 1-3, honorary degrees were conferred on Drs Torald H Sollmann, dean Western Reserve University School of Medicine, Cleveland, William S McCann, director, department of medicine, University of Rochester School of Medicine, Rochester, N Y, and Henry S Houghton, director, University Clinics, University of Chicago. Drs Houghton and McCann are graduates of the college of arts and sciences of the university

Academy Asks Changes in Operation of General Hospital—The Cincinnati Academy of Medicine recently adopted resolutions protesting against various conditions at the Cincinnati General Hospital. The resolution asked that members of the staff of the hospital and of the faculty of the University of Cincinnati College of Medicine be forbidden to practice privately except under the same conditions as other physicians of the city. This point related to the fact that staff members are supplied with offices, telephones and secretaries at public expense for conduct of private practice it was explained. The academy also asked that laboratory services be confined to the needy poor and that the hospital should not give service to persons living outside the corporate limits of Cincinnati. Other changes recommended concerned improvement of teaching of interns and limitation of duties of interns and residents to patients in the city hospital establishment of contracts between the salaried members of the staff and of the university and definition of the status of the Christian R Holmes Memorial Hospital. Finally the resolution asked that policies concerning the care of the needy be adopted only after consultation with a committee of the academy, as some 200 physicians are giving their time and services without compensation to the general hospital and the university

PENNSYLVANIA

Society News—Drs Elliott B Edie, Uniontown, and Arthur D Hunger Point Marion, addressed the Fayette County Medical Society, Uniontown, March 1 on "Spontaneous Hyperinsulinism and Intravenous Use of Dilute Hydrochloric Acid," respectively.—Speakers before the Allegheny County Medical Society, Pittsburgh, February 20 were Drs Edward J McCague on "Surgical Kidney—Clinical Manifestations and Management," Charles H Henninger "Effects of the Economic Depression on Mental Health," and Ralph Lynch, "Albuminuria."—Dr William H Mayer, Pittsburgh addressed the Beaver County Medical Society, Rochester in February, on "Newer Treatment of Neurological Conditions as Applied to General Practice."—Drs Alexander Randall Philadelphia and Roscoe G Leland director, Bureau of Medical Economics American Medical Association, Chicago, addressed the Leocoming County Medical Society, Williamsport January 12 on "The Obstructive Uropathies and The Insurance Principle in the Practice of Medicine," respectively. Dr Randall also spoke at an evening meeting on "The Medical Profession of the Present Day" and Dr Leland on "The Emergency Medical Relief Program."—Drs John A Kolmer Philadelphia and John B McAneney Johnstown addressed the Cambria County Medical Society, Johnstown March 8 on "Present Status of Biological Therapy in the Prophylaxis and Treatment of Disease and Treatment of a Case of Carbon Monoxide Poisoning with Methylene Blue," respectively.—Dr Alexander H Stewart Indiana addressed the Armstrong County Medical Society, Kittanning January 9 on "The Social and Economic Life of the Physician."—Dr James G Koshland Lewistown addressed the Mifflin County Medical Society, Lewistown February 1 on "Otitis Media"

Personal—Dr Esmond R Long, director, Henry Phipps Institute, University of Pennsylvania, sailed for Puerto Rico February 22, to give a series of lectures at the School of Tropical Medicine. He will also join in a tuberculosis survey started in February in two of the important industries of the island needle workers and tobacco strippers

Hospital Ship Used as Shelter—Under an agreement with the Philadelphia County Relief Board, the U S Navy has lent to the board the U S S *Meicy* to be used as quarters for destitute persons. The board will spend about \$10,000 reconditioning the ship, which has been out of commission in the Philadelphia Navy Yard. The *Meicy* was converted into a hospital ship in 1917 and made many trips between Brest, France and New York, with sick and wounded soldiers

Society News—Dr Edward L Keyes, New York addressed the Philadelphia County Medical Society, February 28, on "Treatment of Gonorrhea in the Male."—Among speakers before the Physiological Society of Philadelphia, February 19, were Drs Bernard J Alpers and Webb E Haymaker, on "Participation of the Neuroglia in Myelin Deposit in the Prenatal Human Brain," and J F Hughes and Herbert S Gasser, New York "Spinal Cord Potentials Following One and Two Afferent Volleys"

RHODE ISLAND

Tuberculosis and Diphtheria Reduced—The Rhode Island Public Health Commission announces that the death rate from tuberculosis in 1933 was 49.5 per hundred thousand of population, the lowest rate ever recorded in the state. In the four years 1920-1924 the average annual rate was 104.1. A similarly striking reduction has been achieved through a campaign for diphtheria immunization begun in 1922. In the ten years preceding 1922 the average death rate was 20.4 per hundred thousand, in 1933 it was 1.1. The latter rate was a reduction from 4.1 in 1932

TEXAS

The Dallas Clinical Conference—The sixth spring conference sponsored by the Dallas Southern Clinical Society will be held, March 26-30, at the Baker Hotel, Dallas. Fourteen guest speakers will make addresses and conduct clinics and round table discussions. General assemblies will be held each morning the first four days followed by two-hour courses on numerous subjects. Luncheon periods will include round table discussions led by guest speakers and the afternoons will be devoted to clinics at Dallas hospitals. A public meeting will be held the first evening with the following program

Dr Edward H Cary Dallas "What Medicine Has Done for the Public"
Judge C T Freeman Sherman, "The Relation of the Doctor to the Public"
Dr Harvey J Howard St Louis "An American Ophthalmologist in the Orient"
Dr Charles H Best Toronto "The Story of Insulin"

Tuesday and Wednesday evenings will be given over to symposiums in which the subjects will be presented by Dallas physicians and summarized by visiting physicians, as follows: the anemias summarized by Dr Cyrus C Sturgis, Ann Arbor Mich., diagnosis of intracranial neoplasms, Dr Percival Bailey Chicago, abnormal uterine bleeding, Dr Arthur H Curtis, and digestion in the infant, Dr A Graeme Mitchell, Cincinnati. Speakers at the general assemblies will be

Dr William F Braasch Rochester Minn., "Value of Excretory Urography"
Dr Sturgis Diet "Digitalis Diuretics in Heart Failure"
Dr Curtis Etiology "Diagnosis Nonsurgical Treatment of Carcinoma of the Cervix"
Dr Mitchell Indications for Tonsillectomy
Dr Edward C Sewall San Francisco "Curability of Sinus Disease"
Dr Best Role of Liver in Metabolism of Carbohydrate and Fat
Dr James R McCord Atlanta "Conservative Treatment of Eclampsia"
Dr Howard Syphilis of the Eye
Dr John H Stokes Philadelphia, "Management of Syphilis Disease"
Dr John C Meakins Montreal Que., "Prognosis in Cardiovascular Disease"
Dr Fred Rankin Lexington Ky., "Surgery of Nonmalignant Diseases of the Colon"
Dr Bailey "Tumors of the Nervous System in Infants"

A new feature this year will be two clinicophysiology conferences. One on "Diseases of the Liver, Gallbladder and Pancreas," with Dr Lyarts A Graham St Louis discussing the clinical phases and Dr Best the physiologic phase, and one on "Disorders of the Heart and Circulation," with Drs Meakins and Best as speakers. Another feature will be a fracture clinic conducted by Dr George E Bennett associate professor of orthopedic surgery, Johns Hopkins University School of Medicine, Baltimore

UTAH

Annual Registration Due April 1—All practitioners of medicine and surgery holding licenses in Utah are required to register annually on or before April 1, with the Department of Registration, and to pay a fee of \$3. If a licensee neglects to reregister within from ninety days to six months after April 1, his license can be revoked and will be reinstated thereafter only on his paying the delinquent registration fees and an additional year's fee as a penalty.

VIRGINIA

Bill Enacted—H 94 has become a law repealing the laws relating to narcotic drugs and enacting the uniform narcotic drug act.

Correction—The statement appearing in the February 17 issue of THE JOURNAL that Virginia House bill 23 if enacted apparently would make it unlawful for physicians to prescribe lenses or ocular exercises for the correction or relief of any ocular refractive deficiency or deformity or visual or muscular anomaly of the human eye, is in error. This bill has been enacted but it in no way operates to limit the activities of any licensed physician.

WEST VIRGINIA

Bill Enacted—H 337 authorizing the town of Hundred in Wetzel County to levy an annual occupational tax on all physicians practicing within the limits of said town became a law without the governor's approval, March 7. The tax to be imposed may not exceed 2 per cent of gross professional income.

WYOMING

Annual Registration Due April 1—All practitioners of medicine and surgery licensed to practice in Wyoming are required by law to register on or before April 1 with the secretary of the Board of Medical Examiners and to pay a fee of \$2.50. If a licensee fails to pay the fee within three months after April 1, his license can be annulled and it annulled it will be restored to him only on his paying the stated fee, plus \$5 as a penalty.

Society News—Dr. Russell H. Kanable, Bism., was elected president of the Northwest Wyoming Medical Association at a meeting at Lovell in December, and Dr. R. Carlton Trueblood, Cody, was made secretary. At a meeting of the Sheridan County Medical Society in Sheridan, January 9, Dr. William A. Steffen spoke on "Acute Infectious Endocarditis." The Wyoming State Medical Society has selected Casper as its convention city for this year. The meeting will be held July 16-17.

GENERAL

Study of Neoplastic Diseases—The American Association for the Study of Neoplastic Diseases will convene in Baltimore at the Johns Hopkins Hospital March 28-30. This organization is the outgrowth of and will supplant the microscopic, oral cavity and bone diagnostic demonstrations which have been conducted for the last four years under the auspices of Dr. Joseph Colt Bloodgood, clinical professor of surgery, Johns Hopkins University School of Medicine, and his associates in the Surgical Pathology Laboratories of the school's hospital. It was created at one of these demonstrations at the Mayflower Hotel, Sept. 18, 1933, in Washington, D. C. All physicians who have attended one or more demonstrations in the past are eligible for active membership, those in allied professions for associate membership. Annual dues are \$5 and, in addition, there will be an assessment of about \$3 at each of the meetings, four of which are planned annually. Officers elected are president, Dr. Max Cutler, Chicago, vice president, Dr. James F. Kelly, Omaha; secretary, Dr. Eugene R. Whitmore, Washington, D. C., and treasurer, Dr. Janvier W. Lindsay, Washington. Dr. Bloodgood will continue his activities in an advisory capacity.

Academy of Tropical Medicine Organized—Announcement is made of the organization of the American Academy of Tropical Medicine at a conference in Washington, D. C., February 5-6, under the auspices of the National Research Council. Officers elected were Drs. Theobald Smith, Princeton, N. J., president, Charles F. Craig, New Orleans, vice president, Earl B. McKinley, Washington, secretary, and Prof. William W. Cort, Ph.D., Baltimore, treasurer. It is the aim of the new academy to stimulate interest in all phases of tropical medicine, to provide current surveys of work in progress, to coordinate

American work to prevent duplication, to function as a central source of information for investigators, to cooperate with other agencies in the same field and to receive and administer funds through grants for specific projects. At the close of the conference President Cloyd H. Marvin of George Washington University tendered to the academy a gold medal to be awarded at appropriate intervals for distinguished work in the field, in tribute to members of the faculty of the school of medicine who have become prominent in tropical medicine. The names of charter members, not more than fifty, will be announced three months from the date of the conference.

Medical Bills in Congress—*Changes in Status* S 822 has been reported to the Senate, with recommendation that it pass (S Rept. 406). The bill would authorize the Postmaster General to permit the transmission in the mails of poisonous drugs and medicines to cosmetologists and barbers. S 2101 to prohibit the sending of unsolicited merchandise through the mails has been reported to the Senate with recommendation that it pass (S Rept. 385). H. J. Res. 257 has been favorably reported to the House of Representatives (H Rept. 864). The bill authorizes the Secretary of Interior to arrange with the several states for the education, medical attention, relief of distress, and social welfare of the Indians. H. R. 7059 has been favorably reported to the House (H Rept. 861). The bill provides for the further development of vocational education in the several states and territories. H. R. 7295, the Treasury Department appropriation bill, has passed the House and Senate. It authorizes an appropriation of \$23,032 for special studies of, and demonstration work in rural sanitation. *Bills Introduced* S 2985 introduced by Senator Davis, Pennsylvania, proposes to authorize the acceptance of radium in payment of war debts from Belgium, and for the donation of such radium to hospitals, medical clinics and medical research organizations in the United States. H. R. 7959, introduced by Representative Grisque, South Carolina, proposes to grant uniform pensions and benefits to veterans, their widows and dependents. It would authorize the furnishing of hospital treatment to veterans of any war who suffer with disease or injuries requiring treatment which incapacitate them from earning a living, and who have no adequate means of support. H. R. 8056, introduced by Representative Lundeen, Minnesota, proposes to grant pensions and increases of pensions to certain soldiers, sailors and female nurses of the war with Spain, the Philippine insurrection and the China relief expedition and others. Pensions for contract nurses are provided for under existing law. No pension is provided under existing law or in the proposed bill for contract surgeons. H. R. 8242, introduced by Representative Dunn, Pennsylvania, proposes to grant pensions to certain blind persons. H. R. 8283, introduced by Representative Disney, Oklahoma, proposes, among other things, that any World War veteran, not dishonorably discharged, suffering from disability, disease or defect, who is in need of hospitalization or domiciliary care and unable to defray the necessary expenses therefor, shall be furnished necessary hospitalization or domiciliary care in any veterans' administration facility, within the limitation of such facilities, irrespective of whether the disease, disability or defect was due to service. A statement by the veteran on such form as may be prescribed by the Administrator of Veterans Affairs shall be accepted as sufficient evidence of inability to defray necessary expenses. H. R. 8399, introduced by Representative Buckbee, Illinois, provides for the payment of old age pensions. H. R. 8458, introduced by Representative Hoeppel, California, would authorize the furnishing of hospital treatment and domiciliary care to the retired personnel of the Army, Navy, Marine Corps and Coast Guard and to all individuals transferred to the Fleet Naval Reserve and Marine Corps Reserve after sixteen or twenty years of service. H. R. 7977, introduced by Representative Guver, Kansas, would authorize the Reconstruction Finance Corporation to grant loans to publicly and privately controlled colleges, universities and other institutions of higher learning. H. R. 8037, introduced by Representative Stokes, Pennsylvania, proposes to grant military status to "civilian clerks, engineer service at large," who served overseas in the Engineer Corps of the United States. H. R. 8206, introduced by Representative Bulwinkle, North Carolina, would authorize medical and hospital treatment for veterans of any war who have no adequate means of support and who are suffering with permanent disabilities or tuberculosis or neuropsychiatric ailments, or such other conditions requiring emergency or extensive hospital treatment as may be prescribed by the Administrator of Veterans Affairs, which incapacitate them from earning a living. S 2839, introduced by Senator Capper, Kansas, proposes to provide old age compensation for citizens of the United States.

Feb 17, 1934

Bill to Restrict the Sale of Contraceptives

In the house of lords, Lord Dawson, president of the Royal College of Physicians, moved the second reading of his bill to restrict the sale, display and advertisement of contraceptives. He said that birth control was here to stay but children and young persons should be protected from having contraceptives pushed at them either by means of automatic machines in public streets or by lurid display in shops. General condemnation of the trade in contraceptives only did harm by driving the sale into underground channels. A wider acceptance of birth control in theory as it was already accepted in practice would turn the sale into normal channels. The same was true of propaganda. If clinics were supported where sane information could be given lurid publications would cease to be profitable. The sale of contraceptives in this country had gone up by leaps and bounds. One firm turned out 8500 000 a year and another 72 000 a week and that was reinforced by importations from abroad. Those who opposed birth control belonged almost exclusively to middle aged and late life, whereas the younger generation of parents practiced it and scarcely discussed it. Human nature had not changed since the forties of the last century, when large families were produced. No one would be rash enough to advise them today. Celibacy in marriage was impossible. There had to be either contraceptives and small families or no contraceptives and large families. He gave it as his solemn medical opinion that for young people to have to practice what amounted to celibacy in marriage was impossible and would destroy their health. The whole foundation of Western nations was based on that personal intimacy which involved periodic physical expression of love. In 1847 the infant death rate was 172, sufficiently high to act as a safety valve for the too many children born. Today it was down to 65. The purpose of the bill was to protect immature youth by preventing the obtrusive display of contraceptives. In the debate the bill received general approval, but Lord Dawson's views on the necessity for contraception aroused a good deal of protest, particularly from the bishops.

The Danger of Carbon Tetrachloride in Fire Extinguishers

At the Royal Society of Medicine Sir William Willcox, the government toxicologist, discussed the toxic effects of substances of the carbon tetrachloride group, which are coming into increased commercial use. He said that they were all anesthetics, had a toxic action on the brain were fat soluble and were quickly absorbed. In 1909 a young woman fell dead while having her hair shampooed at a London store. The shampoo contained 4 or 5 per cent of carbon tetrachloride, inhalation of which would give high percentage in the blood. Death was due to the action of the poison on the heart muscle. Recently he had seen three cases of patients in a hospital who had been subjected to the vapor of carbon tetrachloride, which had been used for extinguishing fires on board ship. In all these cases the blow of the poison fell not as he expected on the liver and brain but on the kidney. All showed great impairment of renal function. In one of the most remarkable cases of its kind he had ever seen the urine was completely suppressed for ten days but there was complete recovery. Captain T. Dudley, a naval surgeon, described the cases due to the fire extinguisher that were under his care. In the first case vomiting and gastric disturbance were followed in a few

days by mild jaundice. After ten days epileptiform convulsions with a blood pressure of 220 and blood urea over 300 suddenly began. Edema of the lungs developed and death seemed inevitable but the man made a remarkable recovery. The only change in the urine was mild albuminuria. The patient had only five minutes' exposure to the vapor of carbon tetrachloride. Captain Dudley referred to a more recent fire in an electrical workshop in the dockyard. Thirty cylinders of fire extinguisher were employed and fifteen men were exposed to the vapor varying from five minutes to half an hour. But it was a big well ventilated workshop. One man had nausea and vomiting, but he attributed this to sickly fumes from burning electrical installations. Examination of the men showed nothing abnormal except a trace of albuminuria in one. Captain Dudley suggested that slight cases of poisoning from extinguisher vapors were common and easily missed.

State Aid for the Feeding of Children

The question of the minimum diet necessary for health is exciting much controversy in this period of industrial depression. The conflict between two expert committees, who calculate the minimum as 3000 and 3400 calories daily for a man has been mentioned before, but the feeding of children is a separate problem and some anxiety has been expressed as to undernutrition in the families of the unemployed living on state aid. A committee of members of the house of commons has been formed to bring together those who are concerned with every child obtaining at least a minimum standard of healthy living. The committee has issued a manifesto stating that a first charge on the returning prosperity of the nation should be the health of its children. The committee urges that the government provide a daily ration of fresh milk for all children attending state-aided schools and for younger children through the public health department. Also that the government make compulsory instead of optional the powers of local authorities to provide school meals for children who by reason of the poverty of their parents, are inadequately fed, that the government substantially increase the allowance of the children of the unemployed, and that it encourage the extension of municipal housing and schemes of rent rebates when the family income is insufficient. Mr. Boothby, a member of parliament, said that the present allowance under the unemployment insurance act of 50 cents a week per child was insufficient. A pint of milk a day was essential, and this alone would cost 42 cents a week. The British Medical Association scale for the cost of maintenance of children varied from a little over 50 cents to \$1.25. It was proposed to ask the prime minister to receive a deputation on the subject.

Precautions Against Electrical Shocks in X-Ray Rooms

The X-Ray and Radium Protection Committee which consists of experts with Sir Humphry Rolleston chairman, has issued revised recommendations on the precautions to be taken against shocks in x-ray rooms. 1 The floor covering should be of insulated material, such as wood, rubber or linoleum. 2 When permanent overhead conductors are employed they should be not less than 9 feet from the floor. They should consist of stout metal tubing or other coronaless type of conductor. The associated connecting leads should be of coronaless wire kept taut by suitable rheophores. 3 Whenever possible earthed guards or earthed sheaths should be provided to shield the more adjacent parts of the high tension system. Unshielded leads to the x-ray tube should be as remote as possible from the operators and patients. Shock-proof x-ray equipment in which the high tension circuit is completely enclosed in earthed conductors is particularly recommended. Unless there are reasons to the contrary, the metal parts of the apparatus and

room should be efficiently earthed. 4 Main and supply switches should be easily accessible and distinctly indicated. They should not be in the proximity of the high tension system, nor should it be possible for them to close accidentally. The use of quick acting double pole circuit breakers is recommended. Overpowered fuses should not be used. If more than one apparatus is operated from a common generator suitable high tension multisway switches should be provided. In the case of some of the constant potential generators a residual charge is held by the condensers after shutting down. A suitable discharge device should therefore be fitted. 5 A kilovoltmeter should be provided to measure the voltage operating the x-ray tube. Whenever possible a safety spark gap should be provided. 6 Special electrical precautions should be taken in rooms where anesthetics of low flash point are used.

The committee emphasizes the great importance of these precautions. Every step possible should be taken to prevent accidental contact with any part of the high tension system including the tube, the leads and the associated measuring instruments. While shock proof x-ray equipment in which the high tension circuit is completely enclosed in earthed conductors is especially recommended, much can be done with existing apparatus in the way of providing simple devices such as earthed guards to shield the more adjacent parts. Mobile units in particular should be carefully examined before use in every case. Schemes of illuminated warning notices that function when the equipment is 'alive' are useful. Printed first aid instructions for dealing with electrical shock should be available, and the staff should be trained in their use.

The Royal College of Surgeons

The annual report of the Royal College of Surgeons shows that 400 additions have been made to the museum, the greatest pathologic collection in the world. They illustrate normal and pathologic anatomy, human and comparative pathology, surgical instruments and forensic medicine. Among the pathologic specimens are several illustrating favorable results after excision of carcinoma of the larynx, a rare specimen of cirrhotic aneurysm of the coronary vessels, a series illustrating disease of the gallbladder, and specimens of endometritis, polypus and "tarry cyst" of the ovary. Mr. R. H. Burne, curator of the physiologic department, has made some beautiful preparations showing ossification of the skeleton in the embryo. Nine casts of the skeletal remains of Pleistocene man from Peiping caves have been added.

Some Disadvantages of Prolonged Sun Baths

In a series of experiments some years ago, H. Bordier, A. Morel and T. Nogier found that ultraviolet rays transform the hemoglobin of the blood into methemoglobin, a more stable compound. From these experiments *in vitro*, Mr. Bordier now endeavors to explain certain general effects produced by prolonged and too intense sun baths, namely fatigue, asthenia and nervous disturbances. The passage of ultraviolet rays into the capillaries of the skin, whereby they come to act on the hemoglobin, appears to be demonstrated. Their absorption furthermore, is facilitated by the fact that at the same time the infra-red rays of sunlight produce by means of heat a cutaneous hyperemia and the dilatation of the capillaries. In the sun bath the skin surface presented to the rays amounts on an average, to 15,000 square centimeters and the exposure continues for several hours, at the beaches of fashionable resorts during the summer. The formation of pigment does not prevent the penetration of the rays but merely modifies the sensitivity of the skin. Bordier, in a paper read before the Academy of Medi-

cine emphasizes that great prudence must be exercised in the application of sun baths, the employment of which should always be regulated by the physician, for there are certain dangers to which the attention of the public should be called.

Mr. Hartman presented before the same academy the substance of a report by Professor Roffo, on the effects of sunlight on the development of skin cancers, which appear solely on the exposed areas of the skin. Such cancers are preceded by a local hypercholesterolemia, as has been definitely shown by chemical analysis. Roffo was able to produce in rats such cancers experimentally by prolonged exposure to ultraviolet rays. The malignant tumors thus developed are sometimes sarcomas and sometimes epitheliomas.

Conditions for Good Bread Making

Since the World War there has been much complaint in France, over the poor quality of bread on the market, due to it is alleged to an inferior quality of flour. Many physicians have observed that attacks of dyspepsia are cured solely by eliminating bread from the diet. The question was reopened last year, the bakers having introduced generally the use of chemical products in order to secure a dough that will give to the bread a better appearance. But the Academy of Medicine had an order issued prohibiting the use of chemicals, on the ground that they produced harmful effects. Mr. Andre Klum, director of the laboratory of the prefecture of police in Paris, presented recently to the Academy of Sciences in collaboration with Froidevaux and Dubois a communication that sheds new light on the subject. He points out that the baking values of flours depend to a great extent on the properties of the fatty matter, which amounts to about 1 per cent of the whole grain. This fact had been overlooked. This fatty substance opposes the absorption of water in the dough making process. Products that facilitate such absorption improve the flours. The speakers found that in flours produced from foreign wheats the proportion of fatty substances in relation to a unit of weight of gluten was less than in the flours produced from French wheats, especially varieties that yield a high percentage of flour but produce flour of mediocre baking values. It is these varieties that the French farmer has developed to a great extent because they produce a larger number of grains and without requiring a large quantity of nitrogenous fertilizer, which are necessary for the formation of the gluten.

Convulsions in Children

The general assembly of the physicians of France held in January considered as its main topic 'Convulsions in Children'. The practitioners of the departments of France were requested to bring to the assembly all the evidence derived from their clientele. This sort of national inquiry, inaugurated two years ago, has been found to be a much more accurate method than studying the statistics and it is regarded with great favor by the medical profession. It has also the advantage of bringing to the assembly a large number of rural practitioners who have a wide experience. A mass of documents was thus collected, being first sifted by the departmental medical societies and then compared at the general assembly, held in Paris under the chairmanship, this year, of Professor Luzziere of Montpellier. One fact brought out by the discussions is that convulsions in children occur much less frequently than formerly, particularly in the regions of the South and the Center. A result that is commonly ascribed to the health propaganda carried on by the practitioners, with respect to prophylaxis and the crusade against alcoholism. Practitioners are no longer content to accept the idea of convulsions of an 'essential' type that is to say, with no cause outside itself. Most commonly eclampsia in the child is found in connection with various types of fever and particularly in association with adenoiditis and otitis. Arising at the

beginning of a hyperthermia, infantile eclampsia is much less grave than when it appears toward the end of the illness, for then encephalitis is to be feared. It is always grave in pertussis. Especially grave are likewise the convulsions that appear in acute gastro intestinal infections, particularly in connection with epidemics of dysentery as was pointed out by several departments of France. As to convulsions due to dentition and helminthiasis, opinions differed. In any event, they are of a reflex order and benign. More frequently one should seek the influence of alcoholism and of syphilis in the parents. Hereditary influences are very important. One often observes tendencies to convulsions in the same family for several generations. Also obstetric traumas play a part in the etiology. Meningeal hemorrhages of this nature were reported as more frequent than formerly. Spasmophilia is unquestionably a causal factor, but calcemia is unequally distributed throughout France. Convulsions appear before the age of 3 months, and after age 3 (years) the attacks are more serious than those that appear up to that time. The number of fatal cases is relatively small. Lumbar puncture in the grave cases has given excellent results. Hemotherapy, the blood of the mother being utilized is favorably regarded. Epilepsy which was much discussed is, on the whole, infrequent in subjects who have had convulsions in their childhood (from 1 to 10 per cent, at the most). But in adults who have epilepsy, one often finds references to convulsions, which were probably only masked epileptic attacks. The conclusion unanimously adopted was "Convulsions do not constitute a disease but only a group of symptoms. The prognosis is that of the condition that caused it."

BERLIN

(From Our Regular Correspondent)

Jan 29, 1934

Organization of the Kassenärztliche Vereinigung

The organization of the Kassenärztliche Vereinigung Deutschlands is now an accomplished fact with headquarters in Berlin. The Vereinigung is a corporation legally recognized and is under the supervision of the federal minister of labor. It is the only qualified representative of the medical profession in connection with the regulation of medical affairs in social insurance, the ersatzkassen, and the care of the war injured. It draws up the general contracts with the krankenkassen. As the representative of the relations of the physicians to the communes and the social aid leagues, it can enter into agreements concerning the medical care of persons receiving social aid. It can decide on the details and the regulations for the application of medical care. It regulates particularly the admission of physicians to medical attendance and the termination of such privilege, it determines the details affecting economic methods of treatment and the testing of medical performances, including the system of arbitration and it arranges the distribution of the sums collected as compensation. It can make arrangements concerning compensation for the rendering of expert opinions as to the degrees of disability in the service of the insurance companies for special examinations or for the application of treatments by physicians in bath and health resorts. It regulates likewise the relations of physicians to one another.

The membership of the Kassenärztliche Vereinigung Deutschlands is composed of physicians listed in the official register of physicians and the physicians who are admitted for the treatment of the war injured entitled to medical care. Other categories of physicians may become members of the Kassenärztliche Vereinigung. Such physicians may announce at the end of any calendar year that they wish to sever their connections with the Vereinigung. Such notice will take effect at the end of six months. The chairman of the Verband der Aerzte Deutschlands will serve as the federal director of the Kassen-

ärztliche Vereinigung. He will represent the Vereinigung in court and out of court. The authority of the federal director is emphasized in these terms: "The will of the federal director is the sole final authority. It will be the duty of the official aids to carry out his will and to make it plain to every member that only his will has authority. The 'leader idea' can be realized only through absolute subordination of individual views." The federal director may create an advisory board, the members of which may be appointed and dismissed by the federal director. They would serve the federal director as aids advising and supporting him in all administrative matters. For the execution of their tasks, provincial and district centers may be established as needed. The Vereinigung will collect dues from the physicians who are admitted to the medical care of patients. The dues will consist of a fixed amount payable by each member so participating or of a certain percentage of physicians' receipts or of both. These dues may vary in amount and in kind with the various groups of physicians.

The physicians are under obligations to the Kassenärztliche Vereinigung for the fulfilment of their tasks. If a physician does not fulfil his obligations properly action may be taken against him in the form of a warning, a fine, or through temporary or permanent exclusion from medical activity, unless permanent exclusion from certain medical activities is governed by a special procedure. More than one of these penalties may be imposed at the same time. Exclusion from medical activity may, on the basis of the existing regulations or agreements, be limited to certain fields, for example practice in the krankenkassen, in the ersatzkrankenkassen, and the like. The restriction will be in force for two years. The penalty will be fixed by the official director of the district center and must be communicated to the physician in writing, with an explanatory statement setting forth the reasons therefor. Within two weeks, the physician may file objections. The federal director will decide the further details of the procedure. He is empowered to change or nullify the decision rendered.

These statutes effect a thorough and strict regulation of all matters pertaining to the panel physicians. The Kassenärztliche Vereinigung Deutschlands is to be regarded as the precursor of the contemplated reorganization of the medical profession, some of the essential principles of which it has already realized. It will become also an important link in the anticipated federal chamber of physicians (reichsärztekammer).

Concerning the fees of panel physicians, an important agreement has been reached. Beginning Jan 1, 1934, the krankenkassen remit the fees for the services of panel physicians directly to the Kassenärztliche Vereinigung Deutschlands, which in turn distributes the fees among the panel physicians. As already stated, the arrangement gives the Kassenärztliche Vereinigung an opportunity to consider social and demographic points of view in determining the exact nature of the distribution. It makes it possible for the federated leagues of the krankenkassen to introduce much simpler methods of administration. For example, the medical press of recent months has contained arguments for and against the admission of childless physicians to panel practice, some have gone so far as to suggest that childless physicians who have been admitted to practice be dismissed. However, it does not seem likely, to judge from the plans so far worked out that it is the intention of the authorities to exclude from panel practice physicians (either men or women) whose marriage has resulted in no offspring or to dismiss such as have already been admitted to practice. However, with respect to new admissions married persons will be given preference over single persons, and physicians with several children will be favored as against those with few children.

New boards of directors for the "chambers of physicians" have been appointed. The Prussian state ministry has passed legislation whereby the jurisdiction of the general assemblies

of the "chambers of physicians" has been transferred to the boards of directors of the various "chambers." The chairman of the "chamber of physicians" can call a meeting of the members for the discussion of business affairs of the "chambers of physicians," but the membership will pass no motions or resolutions. Since January 1, the board of directors of the "chamber of physicians" has consisted of the chairman and from four to eight members. The chairman and vice chairman are appointed by the minister of the interior, and the other members of the board are selected by the chairman. One member of the board and his substitute must be federal health officers.

Opposition to the Preparation by Laymen of Medicines Prescribed

The Prussian minister of the interior has raised objections to the practice of certain physicians who as a result of demands to exercise economy, place in the hands of patients potent medicines that will accomplish the desired therapeutic effect only when prepared by experts, requesting such patients to prepare their own medicines. By such unsuitable preparation not only is the therapeutic effect endangered but severe damage to health may be produced. One common source of error in the preparation of medicines by laymen lies in the subdivision of ready made products, for example, the division of small sleep-inducing tablets into eight or more portions for administration to young children. The physician often acts under the influence of the *Artenkassen* and public welfare boards which place booklets published by themselves dealing with the preparation of prescriptions in the hands of physicians and urge them for the sake of economy, to resort to this method of prescribing. In the future, such institutions will be held liable for any damage that arises from such preparation of medical remedies if such damage is traceable to any compulsion leading to the improper preparation of individual prescriptions.

The Breslau Institute for Neurologic Research

A new institute for neurologic research was opened in Breslau, January 31, under the direction of Prof. Otfried Foerster. The funds for the erection of the institute were derived mainly from a \$50,000 gift from American friends and pupils of Professor Foerster. The institute has a department of physiology and a department of cerebral anatomy and histology. The institute houses also Foerster's valuable pathologic-anatomic collection.

ITALY

(From Our Regular Correspondent)

Dec 15, 1933

National Congress of Psychiatry

The Società Italiana di psichiatria held at Siena its twentieth national congress, under the presidency of Professor Donaggio.

BRAIN DISORDERS IN INFANTS

Professor Balduzzi, assistant physician in the Clinica neurologica in Genoa, discussed the "Diagnosis of Brain Disorders in Infants." He described how to make a neurologic examination of infants, which, in his opinion, should never be omitted. The diagnosis of the seat and nature of the lesion in the brain is difficult. The speaker called attention to certain symptoms, such as insomnia, convulsions, muscular paralysis and tonic reactions. A physiologic spasmophilia in children has not been spoken of, but thus far the problem of convulsions has not been solved. If an attack is capable of producing anatomic lesions in the brain (sclerosis in the cornu ammonis) theoretically every attack of convulsions in the child is an expression of a brain disorder. But that does not solve the problem as to whether the child will be a normal person or a psychopath. The speaker showed how frequently paralysis escapes the atten-

tion of physicians and explained the value of examining the tonic reactions in studying the development of the nervous system. The kinds of tonic reactions in the child are manifold: reaction of distention, of fixation and of adaptation, reflexes of the neck, reflexes of contralateral extension of the limbs, reaction of support, labyrinthine reflexes of posture, statokinetic reflexes. By making repeated examination of the tonic reactions, one can determine the degree of development of children and ascertain whether it is regular, retarded or pathologic. These examinations require a special personnel and a wide statistical basis, hence the speaker proposed a resolution in which might be submitted to the government and to the Opera pro maternità e infanzia the need of a specialized institute for the study of brain disorders in infants, from the standpoint of neuropsychiatric prophylaxis.

PSYCHASTHENIA

The official paper on the second topic "Course and Outcome of Psychasthenia," was presented by Professor Puca, director of the Ospedale psichiatrico in Reggio Calabria. The modern trend is to include all psychiatry under one head—that of mental dissociation. According to the speaker, the fundamental difference between psychasthenia and obsessive neurosis consists in the fact that the former constitutes the basis—the constitutional and permanent modification of the mental state, on which may develop without any necessary reason the obsession as a provisional manifestation. At the basis of every obsession there is an emotional trauma through which the emotional energy, fixed to a painful experience, creates a nucleus of sensitization—a modification in the organic structure. Every time that the painful experience is repeated, the whole psychosomatic organism feels a reaction which gradually becomes more extensive. The speaker studied 140 cases and found evidence of a potent hereditary influence. The course of these types may be occasional, periodic, remittent, progressive or chronic. Some patients recover under conditions which may be interpreted as stimulative factors, which reflect the psychic reaction to the immediate contacts of reality. These are of a psychologic and of an organic character. Normal outcomes are delirium, schizophrenia, the Cotard syndrome and real or moral suicide.

ADVANCES IN PSYCHIATRIC AID

The third topic, "Accomplishments in the Form of Psychiatric Aid," was discussed by Prof. Bruno Manzoni who considered chiefly what is being done in foreign countries. The criteria for the admission and the dismissal of cases are now characterized by greater generosity and breadth of views. An attempt is being made to facilitate hospitalization, freeing it from excessive bureaucratic practices especially of the coercive character which serve to maintain the distrust shown by Italian public opinion toward psychiatric institutions. Early dismissals as recommended by Bleuler have been found to have practical value, particularly in the schizophrenic types that have scarcely passed the acute stage. Their purpose is to prevent the atmosphere of a psychopathic hospital from influencing the patient harmfully and from creating those secondary manifestations to which Kraepelin has called attention.

These modern psychiatric ideas encounter frequent opposition in the form of the legal requirements, although some recent enactments denote real progress. For example, the English law and the Swedish law of 1931. Bratz, for instance, has established at Wittenau near Berlin, a graduated system of aid. The psychiatric hospital constitutes the central structure, around which are grouped various independent departments designed to meet the needs of the different classes of patients. Independent departments for nervous patients exist also in other psychiatric hospitals of Germany. In Switzerland at Mandrisio a separate pavilion for alcohol addicts has recently been created. In France where the law of 1837 is still in force, Toulouse

has sought to introduce a modern touch by the creation of a hospital admission to which is voluntary.

In the methods of treatment now used in psychiatric hospitals, one observes trends that are in sharp contrast with older methods for example abolition of systematic isolation and less frequent application of the protracted bath and of bedside treatment. These new trends are the results of the "more active treatment" of Simon which constitutes the most important advance of recent years. This method of treatment may be regarded as a form of pedagogy applied to mental diseases. Its purpose is to socialize the patient with respect to his surroundings and it has as its basis order and tranquility at any cost.

In the general discussion it developed that the Simon method has two defects, namely, the exaggerated emphasis on work and the small number of dismissals. The congress approved the idea that the work performed in the psychiatric hospital should be of a purely manual type and not machine work.

Naples was chosen as the next meeting place. The main topics on the program will be (1) Circumscribed Cerebral Atrophies, chief speakers Bonfiglio and Challiol (2) Psychoses Due to Diseases of Metabolism Penta and De Mares, and (3) Ergotherapy in Psychiatric Hospitals Fattovich.

PRAGUE

(From Our Regular Correspondent)

Jan 27, 1934

Medical Activities in 1933

The final statistical returns are not yet available for 1933 but according to preliminary data the health record was satisfactory. The only unfavorable event was the epidemic of influenza, which continued in the early part of 1933 from the previous year and brought also an increased tuberculosis and infant mortality rate during that period. The results for the second and third quarters of the year however, neutralize the unfavorable effect of the influenza outbreak. The natural increase of the population will again be lower than in the previous year because of the low birth rate. The tuberculosis mortality will show a further decline, even though the year of 1933 saw the highest rate of unemployment ever recorded in Czechoslovakia. The government does continued to be paid almost to the same extent as in previous years, which meant that nowhere was there actually want. Attention was paid especially to the feeding of school children.

The economic depression has had a profound influence on public health and medical activities. But the organization of public health in Czechoslovakia has always been conservative, even in prosperous times, and no material reduction in the public health budget was effected in 1933. Through the financial help of insurance bodies it was possible to maintain most of the public health institutions such as dispensaries and preventoria. Hospitals have been able to operate on a normal scale.

On the other hand considerable pressure was felt in medical practice owing to shrinkage of sickness insurance funds. A scheme for the reorganization of sickness benefit was worked out which curtails only the financial benefits but leaves actual medical aid untouched. In spite of that young physicians found it increasingly difficult to obtain employment with insurance bodies which try to maintain the salaries of physicians who were in their service previous to the depression. The uncertain outlook has led even older physicians to urge the adoption of some pension scheme for physicians engaged chiefly in insurance practice. The Savings Bank of Czechoslovakian Physicians has saved many of them from serious losses from the fluctuation of values during the depression.

The times have forced physicians into a closer organization. They are now on a sounder legal basis and have worked out strict statutes on ethical standards. The medical organizations

studied the conditions of medical practice and opportunities for new medical work and there was a discussion opposing the holding of several offices by one individual in medical practice.

The sickness insurance bodies tried to reduce their expenses by eliminating all possible waste, especially in the field of pharmaceutical products. Most of the imported pharmaceuticals have been eliminated from insurance practice. Another important development in sickness insurance is the increased interest of medical practitioners in the administration of sickness insurance bodies. The conviction is growing that physicians will be able to improve their situation in insurance only through active cooperation. This tendency has manifested itself in the formation of mixed committees, with an equal representation of physicians, by which important questions pertaining to medical practice are being decided.

The general dissatisfaction with medical practice in Czechoslovakia has led also to a deeper interest in problems of reform in medical education. Not only the medical faculties but also private groups of practitioners have been studying the possibilities of a better preparation of students for the practice of medicine. Limitation of the free admission of students into the faculties was foremost in this discussion. An almost complete elimination of foreigners from faculties of medicine was effected through the exchange regulations of surrounding countries which do not permit students to export the necessary funds for study abroad.

The faculties of medicine appointed committees to investigate the possibilities of economizing in the conduct of medical education. The only addition to the equipment of the faculties in Czechoslovakia during 1933 was the new orthopedic department of the Brno faculty of medicine. The Prague faculty of medicine lost two members in the deaths of Dr. Vladimír Slavík, professor of legal medicine, and Dr. Václav Rubeska, professor of gynecology. The German medical faculty of Prague lost also two of its members, Dr. Karl Kreibich, professor of dermatology, and Dr. Arthur Biedl, professor of experimental pathology.

Only two important additions to medical institutions can be recorded for the year: a new surgical hospital of the accident insurance was opened in Brno, in which city also foundations were laid for an institute for research in cancer.

In 1933 only two important international congresses were held in Prague: the cardiologic congress in June and the international congress of otorhinolaryngologists in July. The congress of Slavic physicians in Posen was a convincing demonstration of closer cooperation among the Slavic physicians of Europe.

Mendel's Garden Identified

The fiftieth anniversary of the death of the biologist John Gregor Mendel was celebrated in Brno, January 6, in assemblies held by all biologic societies. Mendel's work was reviewed and a further attempt made to trace the physical reminders of his investigations. The garden in the college was identified where he carried out his experiments in the crossing of plants at the time he was a professor. It was learned that he continued his experiments later when he became influential in the Brno convent. No traces of his work at this time could be discovered because all his private correspondence and archives were burned shortly after his death when no one suspected what an enormous influence his work would have on the development of the science of biology. The efforts for the erection of a Mendel institute in Brno have been renewed.

Introduction of Home Nursing Service by Insurance Societies

Attempts are being made to introduce nursing into the homes as an economy measure in the care of the sick. Skilled home nursing is almost unknown in Czechoslovakia among the lower classes. The Central Invalidity Insurance Agency was first

to set aside funds for home nursing for the destitute. Hospital care could not be afforded by such patients, as they do not have any right to hospital benefits under the insurance scheme. The difficulties encountered are twofold. As physicians under the insurance system are paid usually for a single performance, such as a visit or an injection, most physicians have been reluctant to call for the assistance of nurses in the care of patients, seeing in them possible competition for their services. The patients themselves did not welcome the nurses in their homes as they saw in them agents of the insurance bodies, in which they have but little confidence and whom they suspect of spying on them. The insurance bodies see in this nursing service an important possibility for curtailing their expenses for hospital care, and so they are putting through more and more the remuneration of physicians on a per capita basis. At the same time an attempt is being made through educational measures to inspire faith in the nurses.

"Dental Technicians" and Politics

According to the present laws, only physicians having a special qualification in dentistry (one year postgraduate education after a medical diploma) are allowed to perform dental operations. But in addition a limited number of so called dental technicians are admitted to practice dentistry. Dental technicians" who were in practice when the law of 1920 became effective were allowed to continue their vocation but no others were to be admitted to this profession. Dental technicians in previous times did not have any medical qualification. They acquired skill only through apprenticeship and then passed a state examination. Through political influence, an attempt was made to open further possibilities to new apprentices in the offices of dental technicians to establish themselves independently in the practice of dentistry. The medical profession is combating this project vigorously on the ground that only medical qualification guarantees proper work in operative dentistry. The candidates for the diploma of 'dental technician' have more political influence than the physicians, so the proposal has already been presented to parliament. The dental surgeons however have the backing of the medical faculties and scientific associations. Mass meetings of students, physicians and medical faculties have been held and delegations have been sent to the minister of health and to representatives in parliament. The daily press also became interested in the dangers of dental work done by those not properly qualified. This pressure resulted finally in withdrawing this project from the program of parliament, where it had already been placed among the urgent measures.

Marriages

GEORGE GEORGIJEFF EBANDJIEFF, Nanty Glo, Pa., to Miss Elizabeth Borsella of Washington, D. C., February 1.

WILLIAM KAULL JACOBY to Miss Irma Stumbo Reynolds, both of Evanston, Wyo., at Butte, Neb., Dec. 15, 1933.

ADOLPH WILLIAM VERHOFF, Columbus, Ohio, to Miss Ruth Mary Spangler of Portsmouth, Nov. 6, 1933.

MURL JOHN ROBERTSON to Miss Mary Jane Mertens, both of Bayfield, Wis., at Minneapolis, January 3.

CHRISTOPHER M. REYHER to Miss Clara Keller, both of Gary, Ind., at Jeffersonville, January 10.

WALDO FAIRFIELD DESMOND, Newton, Conn., to Miss Miriam Wales at Monroe, January 19.

FLOYD W. CRAIG, Coshocton, Ohio, to Miss Florence Emily Folev of Youngstown, February 10.

GEORGE MARWOOD HOFFMAN to Miss Ruth Behnke, both of Manitowoc, Wis., January 3.

ERLING SVERRE FUGELSO, Mystic, S. D., to Miss Fanny Gardner of Omaha recently.

JOSEPH A. BODVAR to Miss Mildred Mlazonvsky, both of Cleveland recently.

Deaths

Roger Sylvester Morris ☉ Cincinnati, University of Michigan Medical School, Ann Arbor, 1902, instructor in medicine at his alma mater, 1903-1906, associate in medicine, Johns Hopkins University School of Medicine, Baltimore, 1906-1911, associate professor of medicine, Washington University School of Medicine St. Louis 1911-1913. Gordon and Helen Hughes Taylor professor of medicine, University of Cincinnati College of Medicine, member of the Association of American Physicians, and the American Society of Clinical Investigation, fellow of the American College of Physicians, served during the World War, since 1915 director of the medical clinic, Cincinnati General Hospital, author of "Clinical Laboratory Methods," and "Clinical Laboratory Diagnosis", aged 56, died, March 1.

Abraham Lincoln Blesh ☉ Oklahoma City, Chicago Medical College, 1889, professor of clinical surgery, University of Oklahoma School of Medicine, one of the founders, district governor and fellow of the American College of Surgeons, past president of the Oklahoma State Medical Association, Medical Association of the Southwest and the Logan County Medical Society, member of the Western Surgical Association, served during the World War, chief of staff and chief surgeon to the Wesley Hospital, attending surgeon to the University Hospital and chief of the Oklahoma City Clinic, aged 68, died February 20, of carcinoma of the lung.

William Victor Levy ☉ Colon, Republic of Panama, George Washington University Medical School, Washington, D. C. 1907, member of the Medical Association of Isthmian Canal Zone, on the staff of the Samaritan Hospital, formerly chief of the medical service at the Colon Hospital, aged 54, was found dead February 13 while en route to the United States on board the *S. S. Cristobal*.

Maurice Paxton Jones, Youngstown, Ohio, University of Michigan Medical School, Ann Arbor, 1907, member of the Ohio State Medical Association, fellow of the American College of Surgeons, past president of the Mahoning County Medical Society, served during the World War on the staff of the Youngstown Hospital, aged 49, died suddenly, February 13, of heart disease.

Henry Walker Clouchek, Twin Falls, Idaho, University of Michigan Medical School, Ann Arbor, 1900, member of the Idaho State Medical Association, formerly member of the state board of medical examiners, past president of the South Side Medical Society, on the staff of the Twin Falls County General Hospital, aged 56, died, February 19, of cerebral hemorrhage.

Rufus Hansom Hagood, Jr., Honolulu, Hawaii, Jefferson Medical College of Philadelphia, 1911, member of the Hawaii Territorial Medical Association, fellow of the American College of Surgeons, served during the World War, attending eye, ear, nose and throat surgeon to the Queen's and Kauaikealani Children's hospitals, aged 46, died, February 1, of angina pectoris.

Walter Webster Harrington, Kansas City, Mo., Kansas City (Mo.) Hahnemann Medical College, 1907, member of the Missouri State Medical Association and the Associated Anesthetists of the United States and Canada, served during the World War, aged 54, died, February 9, in the Research Hospital, of chronic cholecystitis and uremia.

Frank William Keating, Owings Mills, Md., University of Maryland School of Medicine, Baltimore, 1896, member of the Medical and Surgical Faculty of Maryland, and the American Psychiatric Association, superintendent of the Rosewood State Training School, aged 64, died, February 18, of acute dilatation of the heart.

Adrian Hansford Grigg ☉ Beckley, W. Va., Jefferson Medical College of Philadelphia, 1912, fellow of the American College of Physicians, past president of the Raleigh County Medical Society, served during the World War, aged 45, on the staff of the Beckley Hospital, where he died, January 6, of lobar pneumonia.

James Joseph Brown, Buffalo, University of Buffalo School of Medicine, 1902, member of the Medical Society of the State of New York, on the staffs of Our Lady of Victory Hospital and the Mercy Hospital, aged 64, died, February 23, of cerebral thrombosis, hemiplegia and hypertension.

Joseph Dimock Howe ☉ Pittsfield, Mass., Tufts College Medical School, Boston, 1898, assistant district medical

examiner formerly member of the school board, veteran of the Spanish-American War on the staff of St Luke's Hospital, aged 64, died, January 30, of heart disease

Robert John Mercer Carter * Saginaw, Mich., Trinity Medical College, Toronto, Ont., Canada, 1899, past president of the Saginaw County Medical Society, aged 58, for many years on the staffs of St Luke's Hospital and St Mary's Hospital, where he died, February 9

Boyd Henderson Pope * Kingman, Kan., Washington University School of Medicine, St Louis, 1906, president of the Kingman County Medical Society, aged 57, on the staff of the Kingman Hospital, where he died, January 7, of injuries received in an automobile accident

Edwin Lawrence Kendig * Victoria, Va., Medical College of Virginia, Richmond 1905, secretary of Lunenburg County Medical Society, formerly member of the state senate fellow of the American College of Surgeons, aged 52, died, January 15, of heart disease

Franklin Beverly Kirby, Harrison Ark., Washington University School of Medicine, St Louis, 1904 member of the Arkansas Medical Society, formerly secretary of the Boone County Medical Society, aged 56, died, January 20, of heart disease

Charles H. Furnee, Kittanning, Pa., Vanderbilt University School of Medicine Nashville, Tenn 1898, member of the Medical Society of the State of Pennsylvania, veteran of the Spanish-American and World wars, aged 55, died, February 2

Mieczyslaus Boleslaus Hazinski * East Chicago, Ind., Loyola University School of Medicine Chicago, 1926, deputy coroner, aged 39, on the staff of St Margaret's Hospital, Hammond, where he died, February 17, of septicemia

William Francis Kelley * New York, Columbia University College of Physicians and Surgeons, New York, 1928 aged 41, on the staffs of the Harlem Hospital and the French Hospital, where he died, February 2, of pneumonia

Jonas Samuel Gilbert, Allais, Ky., University of Louisville School of Medicine 1898 member of the Kentucky State Medical Association, served during the World War, aged 59 died suddenly, February 9, of heart disease

John Francis Dooling, Brooklyn Long Island College Hospital, Brooklyn, 1903, member of the Medical Society of the State of New York served during the World War, aged 52, died, February 23, of pneumonia

Jere Augustus Allis, Basking Ridge, N. J. College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889 member of the Medical Society of New Jersey aged 70, died, February 3

Alfred Graham, Los Angeles, Hahnemann Medical College and Hospital of Philadelphia, 1885, aged 84 died, January 20 in the Glendale (Calif) Sanitarium and Hospital of arteriosclerosis and chronic myocarditis

John S. Borneman * Boyertown Pa., University of Pennsylvania School of Medicine Philadelphia, 1878, past president of the Berks County Medical Society, aged 82, died, February 10, of uremia and influenza

John Worthington Jeffries, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia 1928, member of the Medical Society of the State of Pennsylvania, aged 30 died, January 21, of a brain abscess

Charles Lawrence Nay * Jersey City, N. J. Baltimore Medical College 1897, on the staffs of the Christ Hospital and the Margaret Hague Maternity Hospital, aged 65, died, January 31, of cerebral hemorrhage

Edward Meeker Beach, West Long Branch, N. J. University of Maryland School of Medicine Baltimore 1885, aged 80, died suddenly February 9 in Hollywood, Fla., of acute myocarditis and arteriosclerosis

Robert Glenn Grose, Harmony N. C., University of Maryland School of Medicine Baltimore 1924, member of the Medical Society of the State of North Carolina aged 36 died, February 1 of angina pectoris

James Archibald Nydegger * Surgeon U. S. Public Health Service University of Maryland School of Medicine, Baltimore 1892 aged 69 died February 18 in the Union Memorial Hospital Baltimore

Walter S. Downham London Ont., Canada Western University Faculty of Medicine London 1912 lecturer in public health at his alma mater, medical officer of health, aged 53 died Dec. 28 1933

A. Lincoln Leatherman Indianapolis College of Physicians and Surgeons in the City of New York, medical depart-

ment of Columbia University, 1893, aged 69, died January 19, of heart disease

David C. Loewenstine, Rye, N. Y., Cincinnati College of Medicine and Surgery, 1881, formerly health officer of Rye, aged 75, died, January 26, of cerebral hemorrhage and hypostatic pneumonia

Nels Andrew Biorn, Jackson Minn., Minneapolis College of Physicians and Surgeons medical department of Hamline University, 1901, county coroner, aged 59, died, February 4, of heart disease

Randolph Frederick Hunter, Palm Springs, Calif., Willamette University Medical Department Salem Ore., 1906 served during the World War, aged 52 died February 3 of angina pectoris

John Willis Adair, Kenosha, Wis., Homeopathic Hospital College, Cleveland, 1887, served during the World War, aged 69, died February 14, in St Catherine's Hospital, of coronary thrombosis

Richard Elliott Lee, Lincolnton, N. C., University of Maryland School of Medicine, Baltimore 1896, veteran of the Spanish-American War, aged 60, died February 15, of pneumonia

Thomas Frank Liddy, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1889, aged 70, died, January 11, in Ocala, Fla., of uremia

John Moffatt Leslie, Chillicothe, Ohio Medical College of Ohio, Cincinnati, 1876, member of the Ohio State Medical Association, aged 83, died, February 20, of senility

Lewis Henry Fackler * York, Pa. Jefferson Medical College of Philadelphia, 1886, formerly member of the school board, aged 75, died, February 12, of heart disease

Thomas McNamara Leahy * Newfane, N. Y., University of Buffalo School of Medicine, 1930, aged 29, died, January 16, in a hospital at Lockport, of pneumonia

Alton Paul Gorman, Columbus, Ohio, Eclectic Medical College, Columbus, 1928, aged 29, died, January 31, in the White Cross Hospital, of heart disease

Samuel Eden, Brooklyn Hahnemann Medical College of Philadelphia, 1876, aged 82, died, February 8 of burns received while attempting to light a fire

Frederick M. Kremer, Holton, Ind., Central College of Physicians and Surgeons, Indianapolis, 1897, aged 63, died, February 13, of heart disease

Harry Calvert Iles, Prague, Okla. (registered in Oklahoma under the Act of 1908), aged 69, died, January 6, of acute nephritis and uremia

John M. Barthmaier, Philadelphia Hahnemann Medical College and Hospital of Philadelphia, 1890, served during the World War, aged 77, died, February 17, of arteriosclerosis

Edward Payson Geary, Portland, Ore., Jefferson Medical College of Philadelphia, 1882, formerly mayor of Medford, aged 74, died January 14, in the Good Samaritan Hospital

James Samuel Jackson, Belzoni, Miss., Memphis (Tenn) Hospital Medical College 1893 aged 69, died, in October, 1933, of a self-inflicted wound and hypostatic pneumonia

Winfred Merritte Johnston * Johnson Creek Wis. Ohio Medical University Columbus 1898, served during the World War aged 62, died, February 13, of angina pectoris

Ralph Jonathan Goodenow, Detroit, Detroit College of Medicine, 1907 aged 54, on the staff of the East Side Hospital where he died, February 10, of heart disease

George William McPherson, Los Angeles, University of Michigan Medical School, Ann Arbor 1866, aged 92, died, February 2, of cerebral hemorrhage and myocarditis

John Nathaniel Childs, Ideal Ga., University of Georgia Medical Department Augusta 1893 member of the Medical Association of Georgia, aged 73, died in January

James A. Crow, Round Knob Ill., St. Louis College of Physicians and Surgeons 1892 member of the Illinois State Medical Society, aged 71, died February 8

James Bancroft Hallam, Albertson, N. Y. New York Homeopathic Medical College and Flower Hospital, 1914, aged 67 died January 13, of chronic myocarditis

Edward Ames Robinson, Philadelphia Hahnemann Medical College and Hospital of Philadelphia 1893, aged 62, died, February 15 of carcinoma of the esophagus

George Layton Pearson * Youngstown, Ohio, Western Pennsylvania Medical College, Pittsburgh, 1897, aged 64, died, February 11, of carcinoma of the pancreas

Theodrick M. Johnson, Lima, Ohio, Hahnemann Medical College and Hospital, Chicago, 1884, aged 76, died, January 31, in the Memorial Hospital, of uremia

John Berton Allen ☉ Bloomville, N. Y., University of the City of New York Medical Department, 1891, aged 68, was found dead, February 4, of heart disease

Merle Theron Adkins ☉ Durham, N. C., Johns Hopkins University School of Medicine, Baltimore, 1907, aged 58, died, February 21, of coronary thrombosis

James Andrew King, Forest Miss., Tulane University of Louisiana Medical Department, New Orleans, 1911, aged 60, died, Dec. 3, 1933, of angina pectoris

Willis Leroy Hasty, Norway, Maine, Maine Medical School of Maine, Portland, 1908, member of the Maine Medical Association, aged 57, died, January 30

Alvin A. Francis, Knoxville, Tenn., University of Tennessee Medical Department, Nashville, 1885, aged 77, died, Dec. 19, 1933, of lobar pneumonia

George W. Goss, Pawhuska, Okla., Kansas City (Mo.) Medical College, 1889, aged 73, died, January 10, of heart disease and nephritis

William David Bacon, Philadelphia, Baltimore University School of Medicine, 1900, aged 58, died, February 14, in the Presbyterian Hospital

Charles Coleman Jones, Canton, Ohio, Ohio Medical University, Columbus, 1898, aged 60, died, January 5, of cerebral hemorrhage

Zed Vanderman Luke, Columbus, Ohio, Ohio Medical University, Columbus, 1896, aged 67, died suddenly, January 10, of heart disease

John William Crumbaugh, Huntingdon, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1878, aged 78, died, in January

Allan Moore Kimbrough ☉ Norfolk, Va., Medical College of Virginia, Richmond, 1921, aged 37, died, January 15, of heart disease

James J. Dewey, St. Paul, Rush Medical College, Chicago, 1878, aged 78, died, January 2, of cerebral hemorrhage and arteriosclerosis

Benjamin Franklin Simon ☉ St. Paul, Rush Medical College, Chicago, 1900, health officer of St. Paul, aged 63, died, January 15

Charles B. Chidester, Erie, Pa., College of Physicians and Surgeons, Baltimore, 1881, aged 75, died, February 10, of pneumonia

Robert Stephen Reid, Savannah, Ga., University of Pennsylvania School of Medicine, Philadelphia, 1898, aged 62, died, January 4

Harry Wilson Trimmer, South Gibson, Pa., Medico-Chirurgical College of Philadelphia, 1888, aged 70, died, January 15

Jenny M. Morgan, Santa Cruz, Calif., Hahnemann Medical College and Hospital, Chicago, 1884, aged 87, died, January 28

S. B. W. Courtney, Lake City, S. C., Baltimore Medical College, 1902, aged 58, died, February 12, of coronary thrombosis

Jeremiah Edward Black, Chicago, Bennett Medical College, Chicago, 1913, aged 49, died, February 15, of pneumonia

Thomas Colmer Rowe, Coal Bluff, Ind., Long Island College Hospital, Brooklyn, 1866, aged 80, died, January 13

Charles Schwartz, New York, Baltimore University School of Medicine, 1898, aged 63, died, January 18, of angina pectoris

William H. Lester, Dublin, Ky., Eclectic Medical Institute Cincinnati, 1888, aged 69, died, February 16, of pneumonia

Edgar F. Stewart, Indianapolis, Eclectic Medical College of Indiana, Indianapolis, 1908, aged 60, died, January 31

George Henry Coffin, Malden, Mass., Boston University School of Medicine, 1903, aged 82, died, February 8

Joseph W. Jones, Stockdale, Texas, American Medical College, St. Louis, 1894, aged 70, died, January 8

Benjamin F. Evans, Clarks Green, Pa., Albany (N. Y.) Medical College, 1875, aged 82, died, January 30

Harley S. Norton, Troy, Mo., St. Louis University School of Medicine, 1904, aged 55, died, January 19

Robert G. Carter, Chetopa, Kan. (licensed Kansas 1901) Civil War veteran, aged 87, died, February 1

Lasell W. Lyon, Detroit, Rush Medical College, Chicago, 1885, aged 72, died, January 16, in Pontiac

Bureau of Investigation

LIQUID ARVON

A "Dandruff Remover" with Irritating Qualities

The R. L. Watkins Company of Cleveland, Ohio, has for some time had on the market a preparation known as "Liquid Arvon" and sold as a cure for dandruff. Not, of course, that the product is crudely labeled a "cure", "patent medicine" concerns and cosmetic manufacturers are not that frank. Liquid Arvon has been advertised under the slogan "A Sure Way to Get Rid of Dandruff" and as a "Sure Way to Get Rid of Dandruff". Not even this direct statement appears on the trade package, where the claim might come within the purview of the National Food and Drugs Act. According to the trade package, Liquid Arvon is "For Removing Dandruff". No claim that it will remove dandruff appears on the trade package.

No information appears on the label or carton of Liquid Arvon regarding the composition of the product other than that which our present inadequate law requires, "Alcohol, 5 per cent." Under the present Food and Drugs Act there are only eleven drugs and the derivatives of those drugs that have to be

Sure Way to Get Rid of Dandruff

There is one sure way that never fails to remove dandruff completely and that is to dissolve it. Then you destroy it entirely. To do this just get about four ounces of plain ordinary liquid Arvon. Apply it at night when retiring. Use enough to moisten the scalp and rub it in gently with the finger tips. By morning most, if not all, of your dandruff will be gone and two or three more applications will completely dissolve and entirely destroy every single sign and trace of it, no matter how much dandruff you may have.

You will find, too, that all itching and digging of the scalp will stop instantly and your hair will be lustrous, glossy, silky and soft, and look and feel a hundred times better.

You can get liquid Arvon at any drug store and four ounces are all you will need. This simple remedy has never been known to fail.

THE R. L. WATKINS CO., CLEVELAND O

declared in presence and quantity on the label. Some of the most dangerous poisons known are not among the eleven. For instance, arsenic, aconite, carbolic acid, prussic acid, bichloride of mercury, strychnine—to name a few potent substances—do not have to be declared either in presence or in quantity under the present law.

In the past few years a number of cases of more or less severe dermatitis or other untoward effects have been reported following the use of Liquid Arvon. A Massachusetts physician has just written:

I have a patient with an extensive chemical dermatitis with edema and bleb formation of the scalp forehead and lids of one eye following the use of a liquid sold for treatment of dandruff and called Liquid Arvon. sold labeled as such with the name of the manufacturer R. L. Watkins Co. Cleveland Ohio U. S. A.

A New York attorney writes

I have been retained as attorney for a client of mine who has suffered a dermatitis of the scalp due to the use of a hair lotion called Liquid Arvon. Would you please send me a report giving the chemical constituents of this lotion and also advise me whether or not there have been similar cases such as described above either medical or legal or both.

A physician in New York State reported

I have a patient with severe dermatitis from its [Liquid Arvon] use.

A dermatologist in New York City wrote

I had under observation and treatment a patient with an acute dermatitis of the scalp following the use of Liquid Arvon. I wrote to the manufacturers asking them for a list of the ingredients in the preparation but they failed to reply.

From Oklahoma a physician wrote

I have a patient that used Liquid Arvon a hair tonic. He had a severe rash that covered the entire body.

From Idaho came this note from a physician

A patient came in suffering with quite an extensive dermatitis following apparently, the use of a preparation for the hair called Liquid Arvon. Is there any injurious ingredient in this stuff?

There have been other cases reported, but these are typical

As long ago as 1914 the state chemists of Connecticut published in the report of the Connecticut Agricultural Experiment Station the statement that Liquid Arvon "is an extremely dilute alcohol-glycerine solution containing salicylic acid, potassium carbonate and possibly resorcin." In 1930 a chemist connected with an educational institution in New York City reported that he analyzed Liquid Arvon and found it to contain among other things "sodium and potassium arsenites." In view of that, it seemed desirable at that time to have the A M A Chemical Laboratory test the preparation for the absence or presence of arsenic. The Laboratory report follows

LABORATORY REPORT

"An original bottle of Liquid Arvon (the R L Watkins Company, Cleveland, Ohio) was submitted by the Bureau of Investigation to the A M A Chemical Laboratory for a preliminary examination for presence of arsenic. The bottle contained approximately four liquid ounces of a green colored, perfumed liquid, which was alkaline in reaction to litmus. Qualitative tests indicated the absence of heavy metals and phosphates and the presence of an arsenic compound, potassium, one or more phenolic substances such as resorcin and salicylic acid. Five per cent alcohol was declared on the label. Quantitative determinations were as follows

Specific Gravity at 25 C	1.042
Arsenic (calculated as arsenous oxide)	17 per cent

'In terms of Solution of Potassium arsenite this is equivalent to approximately 17 cc of Solution of Potassium arsenite U S P (Fowler's solution) in 100 cc of Liquid Arvon."

Following three reports of more or less severe dermatitis following the use of Liquid Arvon that have come in since January 1, 1934 the A M A Chemical Laboratory was asked again to test Liquid Arvon, purchased in February, 1934 for the presence or absence of arsenic. The Laboratory reported that arsenic was again found

Correspondence

MENSTRUATION AND THE SAFE PERIOD

To the Editor—In connection with Dr Novak's article "Two Important Biologic Factors in Fertility and Sterility" (THE JOURNAL, February 10), kindly allow me a remark or two.

Births can be controlled in a natural or biologic way by complete abstinence (continence) or by observing the periods of sterility and fertility in women. Births can be controlled in an artificial way by making use of chemicals or mechanical devices and by coitus interruptus. In the one case births are avoided and in the other case births are prevented. This distinction is of great importance not only from an ethical point of view but also from a scientific point of view. Hence the expression 'biologic contraception' to indicate natural or biologic birth control does not seem a very happy one. The word 'contraception' should be used only in connection with artificial methods of preventing conception because *contra* connotes prevention rather than avoidance and prevention is not biologic.

Dr Novak remarks that Ogino admits the possibility of fertilization in the five day period preceding the span indicated but considers it very remote. Owing to more precise observations, Ogino has abandoned that position and no longer requires the extra five days.

Dr Novak refers to opponents of the Ogino Knaus theory, such as Grosser Bolaffio and Niedermeyer. Refutation of their arguments as proposed by Ogino Knaus De Guchtencere, Smulders and others is summed up by Latz in his discussion of the Ogino Knaus theories 'The Rhythm' in these words:

They speak in terms of weeks while Ogino and Knaus speak more accurately in terms of days. They did not ascertain the

variations in the menstruation cycles with sufficient accuracy, they tell the situation with reference to the previous menstruation instead of with reference to the subsequent menstruation.

The last point applies especially to the cases adduced by Grosser, to whom Novak appeals.

Taking up the possibility of extraordinary ovulation brought on by coitus, Latz sums up the position of the opponents by saying "So far no proof has ever been given to establish the contention that such ovulations occur in the case of women. Spontaneous ovulation is the rule with all mammals, except three species, and there is no evidence indicating that human beings do not fall into the general rule. Much evidence points in the opposite direction, namely, that ovulation is not brought on by intercourse. The regularity of the menstrual cycle in spite of intercourse when conception does not take place (as for instance after the use of contraceptives), the yellow-body theory, observed facts in overwhelming numbers, to be mentioned later (Q 43), etc.

'In this connection we might quote Dr Hartman (Carnegie Institution), 'the prevailing gynecological notion—namely, that a woman may ovulate and therefore conceive on any day of the menstrual cycle, is based in part upon uncontrolled evidence, in part upon incorrect observations'."

PAUL E. LAWLER, M.D., Chicago

To the Editor—In THE JOURNAL, February 10, Dr Emil Novak, in discussing the safe period, bottom of second column, page 452, states "the nondangerous span being that embraced between the twelfth and nineteenth days, inclusive." This seems to be the direct opposite of his statement earlier in the same paragraph. It does not fit with the observations you make in your editorial in the same issue. If the word dangerous instead of "undangerous" were used or the word "inclusive" construed as meaning from the nineteenth day of the menstrual cycle, through to the twelfth day after, this passage would be obvious. I am pointing to this apparent error because the statement, as it stands, is in entire accord with my previous knowledge and is the teaching that the clergy in my locality are advising in regard to the "safe period." The newer knowledge of the time of ovulation, the life of the ovum and of the spermatozoa make those views untenable. If the passage, as quoted, is correct, I would appreciate a more detailed explanation of these intricacies of the menstrual cycle.

IVAN I. YODER, M.D., Cleveland

[The communication of Dr Yoder was sent to Dr Novak, who replies.]

To the Editor—Your correspondent is perfectly right in his first comment, but not in his second. While the context makes my real meaning clear enough, I regret exceedingly that the slip in words escaped me in reading the proof of my paper. The word 'nondangerous' should, of course, have been 'dangerous.' As for the intricacies of which the correspondent speaks, I believe that these apply only to the case of women with irregular cycles, in whom, as I stated in the paper, there is a greater element of fallibility in the determination of the "safe period" than there is in women with regular four-weekly cycles. In the latter, since menstruation recurs every twenty-ninth day, there is no difference between the Knaus plan of counting forward ten to seventeen days from the first day of the preceding period to derive the safe span and the Ogino method of counting back twelve to nineteen days from the first day of the next period ($10 + 19 = 29$ $12 + 17 = 29$). It is the Ogino plan that is used in the case of women with irregular cycles, based on this author's idea that the fixed portion of the irregular cycle is the postovulatory span and that the time of ovulation cannot be even approximately determined in very irregular cycles by counting forward from the last period.

EMIL NOVAK, M.D., Baltimore

A PLEA FOR UNIFORMITY IN THE BIOLOGIC STANDARDIZATION OF COMMERCIAL PREPARATIONS OF DIGITALIS

To the Editor—The chemistry of the digitalis glucosides is as yet but imperfectly understood. Chemical assay is therefore not feasible and it is necessary to resort to the technique of biologic standardization. Most of the digitalis products now marketed in America are so standardized.

The present situation with respect to the biologic assay of digitalis is unsatisfactory both to practitioners of medicine and to the manufacturing drug firms. The various factors that lead to confusion are as follows:

1 The one-hour frog method is official in the Pharmacopoeia of the United States.

2 Other methods of assay have been devised, and one or another of these is employed for the standardization of commercial products, e. g. the cat method of Hatcher and Brody, the guinea-pig method of Vanderkleed and the Magnus modification of the Hatcher-Brody technique. The establishment of an international unit has also been attempted, and at least one firm markets a preparation said to be assayed in terms of this unit.

3 There is abundant evidence which indicates that the cat method of Hatcher and Brody yields uniform and reliable results and that the relative potencies of different preparations as determined by this method, apply to human dosage. When a specimen is found to be twice as active as another by this method it is also twice as active in man.

4 No standard of potency has been established for preparations that are assayed by the cat method. Thus 1 cc. of a given tincture may contain the equivalent of one-half cat unit, 1 cc. of another tincture may contain 2 cat units. Tablets, pills and capsules vary in like fashion.

When the physician prescribes digitalis, he is entitled to receive a dependable and uniform product. The drug manufacturer requires and is anxious for guidance and support from the medical profession. He is confronted on the one hand by the U. S. Pharmacopoeia which sets its stamp of approval on the frog unit, and on the other hand by a majority of competent cardiologists and pharmacologists, who favor the use of the cat unit.

The Heart Committee of the New York Tuberculosis and Health Association has for a number of years distributed to its constituent cardiac clinics tablets of digitalis leaf standardized by the cat method of Hatcher and Brody. The tablets have been made up to the strength of 1 cat unit, one-half cat unit and 2 cat units. The experience with this preparation has been entirely satisfactory.

On the basis of the facts cited, the following recommendations are made by the Heart Committee of the New York Tuberculosis and Health Association:

1 For the present and until further knowledge may necessitate a change in point of view, digitalis preparations should be standardized by the cat method of Hatcher and Brody. For convenience the exact procedure now followed in Dr. Hatcher's laboratory is appended.

2 In marketing commercial products, liquid preparations of digitalis should be put up so that 1 cc. (15 minims) contains the equivalent of 1 cat unit.

3 In marketing tablets, pills or capsules of digitalis, each of these should contain the equivalent of 1 cat unit. Tablets, pills or capsules containing stated fractions or multiples of 1 cat unit may be dispensed if desired.

It is hoped that the manufacturing drug firms will adopt these simple suggestions, for by so doing they will be rendering

a real service to the members of the medical profession and their patients.

These recommendations have been approved by the Executive Committee of the American Heart Association.

CAT METHOD OF HATCHER AND BRODY

The cat method of Hatcher and Brody, as carried out in the Department of Pharmacology of the Cornell University Medical College, is as follows:

The digitalis leaf to be assayed is first made up into a tincture, in accordance with the directions given in the U. S. Pharmacopoeia. The tincture is then diluted twenty times with physiologic solution of sodium chloride. The diluted tincture is injected slowly and continuously from a buret into the saphenous vein of the cat until death results from ventricular fibrillation. The rate of injection is such that the total dose is injected in about ninety minutes. The test may be made during light ether anesthesia or only local anesthesia may be employed, 1 per cent procaine hydrochloride being injected or 10 per cent phenol being rubbed into the skin for the exposure of the vein. Six cats are usually employed for one test. Pregnant, lactating or excessively fat animals are not used.

The cat unit potency of the preparation is the average of the results obtained with the group of animals and is expressed as the volume, in cubic centimeters, of undiluted tincture per kilogram of the animal required to cause death under the conditions described. The amount of leaf contained in this unit of tincture is readily calculated.

APPENDICITIS

To the Editor—The excessive death rate from appendicitis is at last attracting nation-wide attention and the question is being seriously raised as to whether many of the operations for appendicitis are justified and necessary. As a statement of fact I submit the following tabulation of appendicitis admissions and operations for seventy-five leading hospitals in this country.

Appendicitis in Seventy-Five American Hospitals, 1923-1932

Year	Cases Treated	Number of Operations	Per Cent
1923	18,194	16,700	92.3
1924	19,197	17,893	93.2
1925	21,298	19,899	93.4
1926	21,916	20,706	94.7
1927	23,673	22,461	94.9
1928	24,162	22,686	93.9
1929	25,495	24,883	97.6
1930	26,094	24,576	94.2
1931	25,271	24,886	98.5
1932*	26,261	24,642	93.8
Total	231,561	217,237	93.8

Total for 142 hospitals during 1923-48,000 cases and 46,848 operations

during the decade ended with 1932, numbering in the aggregate 231,561 cases and 217,237 operations, or 93.4 per cent. This figure is slightly impaired in absolute accuracy by the inclusion of operations for appendicitis that were found necessary in the surgical treatment of patients admitted and treated for other ailments. But this error would not very seriously impair the accuracy of the conclusion that on the average over 90 per cent of the patients with appendicitis are operated on.

The percentage of operations shows no pronounced upward tendency, but the actual number of patients treated increased from 18,194 in 1923 to 26,261 in 1932, while the actual operations

increased from 16790 to 24,642. The highest proportion of operations, 947 per cent, was reported for the year 1925.

Many of the statements regarding appendicitis in this country are, however, grossly misleading. In the November 1933 issue of the *New Health Magazine*, London, for example, is an editorial in which Dr. Ochsner is quoted to the effect that "appendicitis was now causing more deaths than cancer, with one person in the United States dying every twenty-nine minutes from appendicitis." This report is inaccurate for the total number of deaths from appendicitis in the United States registration area in 1932 was 16,978, while the number of deaths from cancer in the same area and for the same year was 122,339.

In several cities, particularly Philadelphia, in recent years various efforts have been made to study the appendicitis mortality from a new standpoint. The work in Philadelphia is especially encouraging and a decided improvement is noticeable in the returns. According to my own appendicitis review, the death rate for appendicitis in sixty American cities with an aggregate population of 29,000,000, was 157 per hundred thousand in 1932 against a rate of 133 in 1910. The rate reached a maximum of 18 per hundred thousand in 1929 and maintained the same figure in 1930, declining to 174 in 1931 and 157 in 1932. The increased attention to appendicitis on the part of the medical and surgical professions is therefore apparently producing encouraging results. In Philadelphia, as I have said before, a special effort has been made to study and reduce the mortality from appendicitis, the rate having declined from 139 per hundred thousand in 1931 to 113 in 1932, against a rate of 148 for New York and 145 for Chicago.

ASCHHEIM-ZONDEK TEST FOR PREGNANCY

To the Editor—I am writing to get some specific information on the Aschheim-Zondek test for pregnancy. The particular information I wish is with regard to the following two cases: 1. A married woman aged 25 who has severe diabetes has had two attacks of diabetic coma that were nearly fatal and her life was saved only by heroic treatment. She has skipped her last period and is about two or three weeks overdue. (a) I should like to know the earliest date on which the Aschheim-Zondek test might be expected to be positive in case she is pregnant. (b) She is receiving large doses of insulin. Would that influence the test? 2. A married woman aged 21 has suffered from irregular menstruations ever since menstruation began. Usually she goes over her periods rather than under them. She has also had a low grade secondary anemia but the menstrual disturbance probably has an endocrine basis. She has been taking anterior pituitary gland and corpus luteum. She is now two weeks overdue but states that there is no chance of pregnancy. (a) In such a case how early would the Aschheim-Zondek test be positive? (b) Would the administration of pituitary and corpus luteum affect the reaction in any way of the Aschheim-Zondek test? What is your experience with the reliability of this test? What is the percentage of false reactions? What if any conditions will produce a false reaction? J. CORVIN MABEY, M.D., Montclair, N. J.

ANSWER—1 (a) Positive Aschheim-Zondek reactions are reported as being obtained as early as two or three days "before the appearance of the next anticipated menstruation." Five days after the first missed period or three weeks after conception is usually regarded as about the earliest that the test can be expected to show positively.

(b) Baumerstein (*THE JOURNAL*, Sept. 30, 1933, p. 1095) has observed that urine of diabetic patients in two instances has caused sudden death of the rabbits used for the test, but nothing has been found in the literature to indicate that the test proper is interfered with by the urine from a diabetic patient receiving insulin.

2 (a) If the cessation of menstruation is the result of pregnancy the Aschheim-Zondek test can be expected to reveal a positive reaction by the time the menstrual period is two weeks overdue.

(b) Medication with pituitary and corpus luteum preparations would tend to cause a positive Aschheim-Zondek reaction and workers advise that it should be discontinued before the test is performed.

The original Aschheim-Zondek test and its later modification by Friedman and by Schneider, in which rabbits are used in place of mice, has given excellent results in the hands of careful workers. Aschheim reported 98.6 per cent accuracy (The Early Diagnosis of Pregnancy, Chorionepithelioma and Hydatidiform Mole by the Aschheim-Zondek test, *Am J Obst & Gynec* 18:335 [March] 1930). The test is strongly positive in hydatidiform mole and in chorionepithelioma. Retained placental tissue, as long as vital vascular contact remains, will give a positive test.

Ziserman (*Am J Obst & Gynec* 26:204 [Aug] 1933) in a review of the incidence of false positives and reports on 356 tests covering a series of problem cases states that 178 patients were pregnant and that 93.7 per cent gave positive Aschheim-Zondek tests. A modification of the Friedman test was used. Of the patients, 178 were not pregnant and 94.4 per cent gave negative Aschheim-Zondek reactions, 5.6 per cent gave falsely positive results. The climacteric, primary ovarian hypofunction, ovarian cysts with amenorrhea, and hyperthyroidism were some of the conditions found in the falsely positive group.

Genital carcinoma may give a falsely positive Aschheim-Zondek reaction and to this class belongs the teratoma and seminoma of the testis in the male.

Bishop (*Gyn & Hosp Rep* 83:308 [July] 1933) states that disorders of the pituitary may cause an excess of prolactin (anterior pituitary-like factor) in the urine.

STERILITY AND ARTIFICIAL INSEMINATION

To the Editor—A healthy woman aged 39 is desirous of another pregnancy. She has three healthy children: two girls and one boy aged 10, 8 and 4. Prior to the birth of the youngest child one miscarriage occurred at 2 months; the cause is stated to be running fast for a considerable distance. Prior to the first pregnancy the woman was told by a renowned obstetrician that it must have been difficult to conceive because of the position of the cervix. The menses occur from twenty-six to thirty days regularly and are of three to four days duration. Beginning about ten days to two weeks prior to their occurrence there is pronounced aching in the thighs followed by discomfort and soreness in both breasts. The woman is subject to severe migraine headaches. For the last six months no precautions against conception have been practiced. Squibb's Follutein two 5 cc vials were given intramuscularly with failure of pregnancy. The last injection was followed by a severe reaction: chills, fever and vomiting. The knee-chest position has been resorted to in coitus during the last two months on numerous occasions in the hope of increasing the possibility of conception with failure. Elevation of the hips on pillows and prone coitus also have resulted in failure to conceive. The cervix is in a healthy condition but with a pronounced rectocele and relaxed perineum. The uterus is in good position. Motile spermatozoa are found in the semen of the husband who is in good health and presents no venereal history. Would a rectocele and a bulging anterior to the cervix be the cause of failure? The vagina is long and deep. Would artificial insemination with a syringe be advisable and safe? If so please give suggestions as to technique. Would getting out of bed following coitus and losing some of the seminal fluid be a factor or preventive to conception? The woman states that in the prone position much of the seminal fluid is lost following coitus but not in the knee-chest position. What would be the most likely time to conceive and what is the likelihood of having another boy? Males predominate in both sides of the family. She hopes to avoid surgery if possible though she is willing to submit to dilation but wishes to avoid curettage if possible. She is needed at home because of the children. Please omit name and address. M. D. Idaho.

ANSWER—A rectocele and cystocele rarely ever interfere with conception. Even women with a partial prolapse of the uterus can conceive. The loss of seminal fluid does not usually result in sterility because in most instances, enough semen is deposited on the cervix during ejaculation to permit impregnation. However, when the cervix is not in the line of ejaculation, the loss of semen immediately after coitus may play a part in sterility. Nevertheless, even in these cases, enough semen remains in the vagina to permit fertilization. As a precaution however in cases of sterility when there is a tendency to the loss of semen the patient should remain in bed for at least half an hour after intercourse with her hips elevated on a pillow or stay in the knee chest or Sims position for ten or fifteen minutes.

Before insemination or even a dilation is resorted to, the contents of the cervical canal should be aspirated immediately after coitus and examined to see whether motile spermatozoa are present in this medium. A Rubin test should be performed to make certain that the fallopian tubes are patent, even though the patient has had three children. Not infrequently pregnancy

follows such a test, even when the tubes are permeable. If no gestation follows such a test, it may be advisable to perform a dilation and a mild curettement, because conception occasionally occurs after this procedure. The last resort is artificial insemination. Both husband and wife must be told that attempts to impregnate the woman artificially will most likely have to be carried out many times over a period of months. Even then there may not be a successful result. The most favorable time to carry out this procedure is the ten days that occur midway between the first day of one menstrual period and the first day of the next expected menses. The ideal time for conception to take place is at the time of ovulation, which usually occurs about midway between menstrual periods. Since ovulation may occur any time from the tenth to the eighteenth day of the cycle it is advisable to inseminate three, four or five times during these ten days. The husband should be instructed to wash the penis with soap and water before coitus and the wife should take a sodium bicarbonate or salt water douche. There are four methods of procuring semen—masturbation, coitus interruptus with ejaculation into a small jar, coitus condomatus, and natural coitus followed by aspiration from the vagina. The most aseptic method and the one that is not too obnoxious is to have a small sterilized jar at hand before intercourse. At the time of the orgasm the semen should be ejaculated into this jar. The latter should be immediately brought to the doctor's office. The patient is placed in the lithotomy position as for a vaginal examination and the vagina carefully cleansed. The cervix is exposed with a bivalve speculum and the external os is further cleansed. However, it is not advisable to apply any antiseptic because this may destroy the spermatozoa that are to be injected. The cervix is grasped with a tenaculum and a uterine cannula is gently inserted into the uterine cavity. The semen in the jar is drawn up into a luer syringe and 1 or 2 cc of it deposited in the uterine cavity, very slowly. If the semen is injected too quickly, it will be expelled by uterine contractions. After the injection is performed, the cannula should be removed slowly and the patient should lie quiet on the examining table for about thirty minutes. It is best to examine some of the semen just before each insemination, to make certain that it is satisfactory.

At present there is no dependable way of selecting the sex of offspring in human beings. However, Unterberger maintains that if sodium bicarbonate is applied to the penis and in the vagina before intercourse a boy will result from the impregnation. Thus far no one has verified Unterberger's contention.

DIAGNOSIS AND TREATMENT OF ASPERMIA

To the Editor—A young couple married four years want a baby. The man has never had a seminal emission. After intercourse his urine appears milky and contains numerous spermatozoa. My diagnosis is congenital absolute aspermia, probably due to faulty direction of the ejaculatory canal. Is there a way for him to have a child of his own? Can one obtain semen by aspirating the testicle? What is the technique of that procedure and of artificial fertilization in detail? Has it been done before? Please omit name. M D

ANSWER—The diagnosis of aspermia, absence of ejaculation of semen, may be made by a complete genito-urinary examination. The appearance of the ejaculatory duct openings can be determined by a posterior urethroscopy, and with proper technique the ducts themselves may be catheterized. In some cases a tight urethral stricture may be the cause of the condition. In other cases the fault lies in the sexual centers themselves. In some cases the condition has been artificially acquired by the patient holding back his ejaculation during coitus or masturbation. In some of these cases fluid containing live spermatozoa may be obtained by vigorous massage of the prostate combined with expression or stripping of the seminal vesicles at the same time. This procedure is best done when the bladder is full. In other cases a nocturnal pollution will be found to contain numerous live spermatozoa.

Before resorting to more radical procedures an attempt should be made to correct or cure the aspermia. In the absence of some of the pathologic conditions mentioned, a cure may at times be brought about by prostatic massage and weak silver nitrate solutions (from 1,000 to 1,500) into the prostatic urethra. Of course if the posterior urethroscopy reveals some severe pathologic condition, especially in the neighborhood of the ejaculatory duct openings, this should be treated locally.

If the aspermia itself cannot be relieved, and spermatozoa can be obtained from the seminal vesicles and prostate by expression, this fluid aseptically collected, may be put just within the cervical os care being taken not to inject it into the fundus uteri, as severe cramps or even a serious reaction may result.

The same may be done with the fluid obtained from a pollution with the aid of a condom. If spermatozoa cannot be obtained from any of these sources, one may administer to the patient enough sodium bicarbonate to render the urine mildly alkaline and collect the urine under aseptic precautions after a coitus, and procure some of the sediment which contains the spermatozoa and deposit this about the external os. Either of these procedures should be done shortly after the cessation of menstruation.

It is possible to obtain a few spermatozoa by aspiration of the testicle. The technique is quite simple and is described in detail by Hühner (Aspiration of the Testicle in the Diagnosis and Prognosis of Sterility, *J Urol* 19 31 [Jan] 1928). Briefly, the skin over the testicle is painted with iodine, and a rather large bore hypodermic needle, attached to an ordinary hypodermic syringe, is plunged through the skin at this point and into the testicle, and suction is maintained throughout the withdrawing of the needle. No anesthetic is used or is of any use, as whatever pain is caused is testicular in character and quickly disappears. A small amount of collodion may be applied to the puncture site after removal of the needle. Unfortunately, the number of spermatozoa obtained is so small that the procedure for this purpose has been found useless. The aspirated fluid thus obtained has been injected into the female cervix, both pure as well as mixed with a weak sodium bicarbonate solution and also mixed with some of the patient's own prostatic secretion. Various attempts in this direction have been made by Hühner as well as others, but so far there has been only one successful case briefly reported by Kenneth Walker in his book 'Male Disorders of Sex' on page 177.

INJECTION TREATMENT OF VARICOSE VEINS

To the Editor—About 5 cc of sodium morrhuate solution was injected into a varicose vein Aug. 15, 1933. None of the solution escaped into the surrounding tissues. The tortuous vein has remained hard and has absorbed scarcely at all. The usual tests for deep circulation were carried out before the injection. The patient has since complained of pain in the leg and swelling of the ankle. October 21 the patient complained of an intensely irritating rash over the entire body, and especially in the region of the varicose veins. The rash was punctate and raised confluent over the arms and in circinate arrangement over the other parts of the body. She complained of severe irritation which has only recently been entirely alleviated. This rash has never been of the weeping type. I felt at the time that the rash was due to ingestion of some food and could not reconcile myself to the idea that it could possibly be due to the injection given. Is it possible that the latter could be the cause? If so what might have been done to help the condition? What can be done to hasten absorption of the mass of veins?

ARTHUR S. LEAVITT, M.D., Los Angeles

ANSWER—The reaction should be discussed under two heads.

1 The thrombosis of the vein giving the firm hard cord is what is desired but probably is more painful and has more tissue reaction about it than usual, because of the large dose injected. 5 cc of 5 per cent sodium morrhuate being too large a dose to inject into any vein through one needle puncture. Just this reaction will often follow excessive doses of this solution.

2 The rash is very annoying and is also seen only in those cases in which a massive dose has been used and seems to be more prone to occur if a large dose is used in one injection. The rash greatly resembles an anaphylactic reaction. Its termination may sometimes be hastened by highly alkalinizing the patient and forcing fluids.

TREATMENT OF TABES

To the Editor—I have a patient who has severe symptoms of tabes. During the past ten years he has been through several courses of treatment and his blood Wassermann reaction at present is negative. However his symptoms are rapidly becoming worse so that at present he is almost unable to walk. Please give me a brief summary of the newest method for treating a case of spinal syphilis of this type. Please do not publish my name. M D, Illinois

ANSWER—Much depends on what one finds in the examination of the cerebrospinal fluid. If this is completely negative as is examination of the blood, one would feel that the lesion is of a late degenerative type, for which little, if anything, can be done. If, on the other hand, one finds evidences of an active inflammatory process in the examination of the fluid, there is some possibility of improvement by the use of trypanasamide or fever. The latter can be produced either by malaria or by diathermy, the electrical blanket, or intravenous injections of typhoid serum. When tabetic ataxia has reached the stage at which walking is impossible, one may assume that a great deal of destruction has taken place and that there is only a relatively small chance of any improvement.

HEREDITARY IN CANCER

To the Editor—My husband's mother died at 47 years of age of carcinoma of the liver. His father died in his late fifties as a result of metastasis of a prostatic cancer. Four years ago a half sister (same mother) died at 47 years of age of carcinoma of the liver diagnosed at the University of Michigan Hospital. Operation was begun but the condition proved to be too far advanced to be benefited by surgery. My husband was healthy as a child with the usual childhood diseases including scarlet fever. During 1921-1922 while teaching in Japan he had an eye infection diagnosed trachoma which was overtreated; he suffered a nervous breakdown and returned to this country where he recovered. When he married in 1925 he had been suffering from severe sick head aches which have since been eliminated by diet and exercise only an occasional one appearing under severe nervous strain. He has an occasional cold and the hearing in the left ear is slightly impaired. At 36 years of age somewhat overweight he is apparently in excellent health. What tests or examinations can be made what mode of life can be outlined to anticipate the fate of his immediate relatives? Any light on this problem will be appreciated. Please omit name. M D Ohio

ANSWER—The first thing to consider is the fact that the existence of the cases of cancer in this man's family do not necessarily, or even probably, mean that he will suffer from the same disease. He undoubtedly has many other relatives who did not die of cancer, and so while it may well be that he has a somewhat greater possibility of eventually acquiring cancer than another individual who did not have so many close relatives with the disease, as far as general experience goes this chance is not much worse than with the average run of mankind. He should take the same precautions that any one should of having periodic physical examinations to disclose any abnormalities that are not producing symptoms, and to seek competent medical advice whenever any unexplained symptoms of any kind manifest themselves. He should be assured that, as far as is now known of the genetics of cancer inheritance, he has no great cause for fear but he has excellent reason for more than ordinary care in seeing that his physical condition is checked up frequently.

EFFECTS OF RAYS ON TESTIS—SEXUAL NEUROSIS

To the Editor—About nine months ago a patient of mine, a man aged 32, was treated by a dermatologist for a lichen planus which failing to respond to ordinary treatment was eventually cleared up by roentgen therapy, a total of fifteen exposures at weekly intervals to the site of the eruption, the upper thighs being required to effect a cure. Three months ago the patient came to me stating that from about the time of the last exposure he had noticed that the testicles and penis were becoming smaller and that the scrotum seemed to be looser and more flabby than before he had received the roentgen treatments. A recent examination of the semen shows normal and active spermatozoa. He does not complain of any change in desire for sexual intercourse but finds that the orgasm is delayed in its completion. There are no evidences of any glandular disturbances and repeated examinations fail to show any abnormal physical changes. There is no history of venereal infection. Could his complaints be attributable to exposure to x-rays? Has there been any recent work done in the field of glandular therapy that might help the patient? What can be done to bring the genitalia back to normal? Please omit name. M D New York

ANSWER—The patient's statement that there has been organic change in the testicles since exposure to x-rays is contradictory to the fact that his physician finds a normal concentration and activity of the spermatozoa in the semen. On the other hand the statement that this observation by the patient coincides with disturbances of sexual function (delayed orgasm) completes the familiar picture of sexual neurosis. The decision whether this is a sexual neurosis can be made only by the physician in charge. There are apparently no recorded effects of x-rays on the genitals other than destruction of spermatogenesis, which has not occurred in this case. One would suppose that the effect of "glandular therapy" in such a case would be psychic, if any. One would also suppose that the genitalia are normal. At least the physician does not say that they are not so. To convince the patient that they are normal will require psychotherapy, formal or informal.

BRONCHIAL ASTHMA IN CHILD

To the Editor—I should like to know the prognosis in the case of a boy, aged 12 years, suffering from bronchial asthma since the age of 6 months. He has had his entire system gone over by numerous specialists in this city and Calgary. At the age of 4 his tonsils and adenoids were removed with no improvement in his condition. During the past six years he has resided in Edmonton and has had numerous skin tests, about eighty in the series and he reacts to most of them. What is the best treatment in this case? He has tried Felsol (an Anglo-French preparation), asthma powders by various pharmaceutical houses and ephedrine. He gets the best relief from ephedrine tablets by mouth. Please omit name and address. M D Canada

ANSWER—The prognosis in children suffering with bronchial asthma is usually good. This is especially true when the disease has been present for only a short time. The prognosis becomes

less hopeful as attack follows attack. This is because emphysema commonly sets in and adds its symptoms to those of the original uncomplicated bronchial asthma. Deformity of the chest is a frequent result of repeated attacks of dyspnea. Emphysema and chest deformity are not curable; the original asthma is curable in many cases even in those who have had it for many years.

As to treatment, it would seem that good care has been rendered. However, there are several hundred skin tests to be made; intracutaneous tests sometimes reveal clues not obtained by cutaneous tests. Diet tests often are of aid.

Failure may also be due to leniency on the part of the parents or the physician. Asthmatic persons must be shielded, as far as is possible, from all possible causes of attacks. Foods that give positive tests should not be given. If egg, for example, gives a positive reaction, the boy should not be allowed egg in any form. In addition, he should be protected against feathers and he should not be allowed to play with dogs, cats or other animals.

Finally, if these measures do not help he should be retested completely with the several hundred different antigens now available. Repeated tests frequently yield interesting information.

It is needless to add that general hygienic measures are of great importance.

TREATMENT OF NEUROSIS

To the Editor—A man aged 24 was given a thorough physical examination about six weeks ago. Everything was normal except the metabolism test which gave a reading of minus 19. He has an oily skin and is taking roentgen treatments for acne. He is underweight (his height is about 5 feet 10 1/2 inches or 178 cm and weighs between 125 and 130 pounds or 56.7-59 Kg) but has a good appetite. He had pulmonary tuberculosis when 6 years old from which he recovered. He sleeps from ten to twelve hours. He has never had duties to do around the house but is a good worker when given work to do. He recognizes that he must work and for this reason wants a job but just cannot bear the thought of it especially if he must leave home. His disposition has always been disagreeable—the kind one has in mind in saying he hates himself. He never has entered into sports but is pleasant enough when he wants to be so if he tries. He recognizes this and says that he just lacks nerve—no ambition but he wants ambition. I fear to have a psychoanalyst see him because he is far from being dull and might get the wrong slant as to its reason. Please comment on this—such as how frequent the metabolism test ought to be made and whether this thyroid extract is enough. Please omit name and address.

M D Michigan

ANSWER—A great deal more would have to be known of the mental and emotional attitudes of the patient before sound advice could be given. An inquiry into and examination of these fields does not necessitate the technical and prolonged procedure of orthodox psychoanalysis. A good psychiatrist with tact and judgment is accustomed to meeting this type of patient and securing cooperation. Certain questions at once occur, such as: Why can't he bear the thought of a job or of leaving home? What has balked the development of normal ambition? Is he worrying about masturbation? Has the low metabolic rate been checked by a second test? What is the pulse rate? The correspondent might be asked how much thyroid the patient has received.

TREATMENT OF GLYCOSURIA AND DIABETES

To the Editor—About three years ago I tested the urine of a friend (who then weighed 250 pounds or 113 Kg) and found a marked sugar reaction. I put him on a diet which promptly cleared up the glycosuria and reduced his weight to 200 pounds (93 Kg), which weight he has since maintained (he is 6 feet [183 cm] tall and 40 years of age). Although he has greatly restricted his carbohydrates when I examined the urine about a month ago there was another strong sugar reaction. He has since restricted his diet still further so that he now weighs 195 pounds (88.5 Kg) and the urine is sugar free. At present if he inadvertently eats a bunch of grapes or a few handfuls of popcorn a glycosuria appears. Aside from this there were no symptoms whatever. Is there anything to be done aside from rigid dieting? Is this a case for insulin? Is it enough that he keep the urine sugar free? M D

ANSWER—From the description of the case, a strict adherence to proper diet would seem to be the correct treatment. Insulin is necessary only when the patient is unable to take a diet that is adequate to maintain normal weight and physical activity, without glycosuria or appreciable hyperglycemia. Since the patient is still above average weight for his height and age (180 pounds, or 81.6 Kg) and since he has no symptoms or signs except for glycosuria following dietary indiscretions, insulin is not indicated.

Ordinarily it is sufficient to keep the urine sugar free but one should determine the blood sugar level from time to time to ascertain whether the urine examinations continue to be an adequate check on the patient's condition. In certain cases the

threshold of sugar excretion in the kidneys may rise above normal, so that a high blood sugar exists while the urine is sugar free. In such cases the treatment must be directed toward the lowering of the blood sugar to the normal range, and the physician must necessarily be guided by more frequent analyses of the blood sugar.

INJECTION OF QUININE AND UREA IN VASOMOTOR RHINITIS—REMOVAL OF UVULA

To the Editor—1 Since the injection of quinine and urea hydrochloride is used in the treatment of hemorrhoids to cause a shrinkage of the tissues could the same treatment be used in vasomotor rhinitis? The patient has had skin tests for pollens and has been treated with autogenous vaccine and calcium with a salt free diet. 2 An article in *North West Medicine* November 1933 gave the author's experience with staphelectomy in the prevention of colds. Is there any proved disadvantage in removing the soft palate? Kindly omit name.

M D Washington

ANSWER—1 Quinine and urea hydrochloride not only has been used in the treatment of hemorrhoids but also was rather extensively employed some years ago for the purpose of producing local anesthesia for tonsillectomy. It was observed, however, that when used by infiltration there was considerable edema of the tissues and sloughing at times occurred. It does not seem logical to use quinine and urea hydrochloride for hyperesthesia, as there is the possibility of edema and sloughing and, furthermore, the essential etiologic factors of the hyperesthesia are not eliminated by injecting substances into or beneath the nasal mucous membrane.

2 There is no particular disadvantage in removal of the uvula but removal of the actual tissues of the soft palate will in many instances lead to changes in the voice. If the uvula is removed flush with the edge of the soft palate there will be no difficulty either with the voice or with the act of swallowing. It is difficult to visualize beneficial effects so far as the prevention of colds is concerned, by the mere removal of the uvula. Unless a large number of cases under control could be observed for several seasons, it would be difficult to arrive at any conclusion regarding the possible benefits from staphelectomy or removal of the uvula.

UNUSUAL DISEASE REPORTED FROM MEXICO

To the Editor—The following item appeared in *El Siglo de Torreón* for Nov. 22 1933 (My own crude translation from the Spanish). Mexico Nov. 21—The health department has received reports from numerous towns and ranches of Sinaloa where it is causing great mortality of the presence of so-called spotted fever, a fever accompanied by excessively high temperature, hemorrhages and black spots over the entire body. The spotted parts decompose and fall in pieces causing the death of the victim in a few hours. Cases have been reported of entire families consisting of from seven to ten persons who died in less than one week. From those places they are asking for physicians to combat the evil which is most highly contagious. I am anxious to know whether this disease is a new entity or whether it has been epidemiologically investigated and reported. If so I would appreciate some report as to its alleged identity. A L MANN M D, Elgin Ill.

ANSWER—In some ways the description given resembles that of Rocky Mountain spotted fever in virulent form. The statement about spotted parts decomposing and falling in pieces does not fit into that picture, because such changes do not occur in rapidly fatal cases. Sloughing may occur in cases of spotted fever after several weeks. If it is true that the disease is actually contagious, it could not be Rocky Mountain spotted fever. It will be necessary for competent investigators to study the disease where it exists to determine its exact nature.

SULPHARSPIRANAMINE IN SYPHILIS

To the Editor—Will you kindly outline (dosage and frequency of dosage) treatment for congenital and acquired syphilis in children from 5 to 20 years with sulpharspiranamine (DePree)?

WILLIAM J JOHNSON, M D Wrentham Mass

ANSWER—Sulpharspiranamine is not to be commended for general use in persons from 5 to 20 years of age, on account of the marked tendency that it shows toward the production of exfoliative dermatitis and aplastic anemia. It is, however, quite well tolerated by very young children in whom a dose of from 15 to 20 mg per kilogram is allowable, the initial dose being 10 mg per kilogram and the highest individual dose not to exceed 0.4 Gm weekly. Courses may consist of from eight to ten injections at weekly intervals given either alone or in conjunction with a bismuth compound. It is inadvisable and in general unnecessary to use the drug after the tenth year of age when an intravenous injection technic becomes easily available. Jeans gives 20 mg per kilogram without any statement as to maximum dosage and Schamberg and Wright give 20 mg per kilogram, no individual dose to exceed 0.4 Gm.

PLANTAR WARTS

To the Editor—I should like some information concerning the infectious or noninfectious nature of so-called papillomas of the foot (plantar warts). At this institution we have had a number of cases of these wartlike tender and painful foot ailments appearing in the course of several weeks and successfully eradicated by repeated applications of dichloroacetic acid. I have been unable to find any opinion concerning this etiology. Please omit name and address. M D New Jersey

ANSWER—The infectivity of warts has long been known, having been demonstrated experimentally by several investigators. U J Wile and L B Kingery (*The Etiology of Common Warts* *THE JOURNAL*, Sept 27, 1919, p 970) demonstrated that the virus of warts is one of the filtrable viruses. They made a mash of the curettings of warts, filtered it through a Berkefeld filter and made cultures on agar. No growth was obtained. They then injected it endermically in a number of cases, obtaining a growth of warts at the sites of many of the inoculations. A filtrate of the juice of these experimentally produced warts also produced warts on endermic injection. It is generally agreed that the smooth topped juvenile warts and plantar warts are examples of verruca vulgaris, all caused by the same virus.

PROGNOSIS OF FRACTURES INTO JOINTS

To the Editor—Would you please give me information as to the prognosis of joint fractures and especially baseball fingers in which a fracture is near the joint? I have a case in which joint is threatened and I should like data on the situation. I want especially data on the likelihood of stiffness. J O HELM M D New Florence Va.

ANSWER—The prognosis of fractures into and near joints depends on several factors including the presence of traumatic synovitis, traumatic arthritis, bony irregularity or bony block. It also involves the degree of reduction, splinting, early active motion, delayed passive motion, and appropriate physical therapy.

In regard to baseball finger, the prognosis depends to a considerable degree on whether there is a chip fracture into the joint or rupture of the extensor tendon.

THE TREATMENT OF GONORRHEAL PROCTITIS

To the Editor—In *Queries and Minor Notes* in *THE JOURNAL* Dec 23 1933 page 2069 a pint of 1:4000 potassium permanganate as a retention enema was recommended for the treatment of rectal gonorrhea. I believe that this is inadequate and unsatisfactory because the majority of patients cannot retain it long enough for it to be of any value. I therefore suggest the following treatment. While the patient is lying on the left side with the right knee flexed 1 ounce (30 cc.) of 10 per cent mild silver protein should be instilled by rubber catheter into the rectum for fifteen minutes. This is performed every second day for three weeks and then followed with 1 ounce of 1:4000 acriflavine base for two weeks. This treatment should be alternated for about three months. The patient is instructed to insert a 10 per cent mild silver protein suppository in the morning and before retiring to take 1 ounce of liquid petrolatum daily by mouth and to maintain a bland diet. All foci of infection in the urogenital tract should receive immediate attention. This method of treatment has three distinct advantages: retention of the medication, prevention of injury to the rectal mucosa and a better ultimate result. HERMAN FEINBERG M D San Francisco

VIABILITY OF SPERM IN FEMALE GENITAL TRACT

To the Editor—In your answer on identification of sperm and seminal fluid in the vagina you state that the sperms disappear from the vagina in two days because of the acidity but live two weeks or so in the uterus or tubes. This is not correct.

In my experiments made from 1925 to 1928 and later reports of which have been published since I have shown definitely that the vaginal acidity is not an important factor but that the body temperature alone other factors remaining the same will kill all sperms in twenty-four hours or so. The limit is certainly not more than from thirty-six to forty-eight hours. It has been expressed very wittily by the statement: The presence of living sperms in the female genital tract two weeks after alleged intercourse is no longer a scientific question but a moral issue. G L MOENCH M D New York.

DUOCHROME METHOD OF REFRACTION

To the Editor—Recently there was brought to my attention a query and minor note in the Nov. 25 1933 issue page 1748 of *THE JOURNAL* regarding the duochrome method of refraction. Some months earlier there appeared a similar query and minor note. In both the text of the answer was mainly condemnation of the method chiefly on the ground that the method is an attempt to do away with the use of cycloplegia. I feel that this is unfortunate for the procedure of duochrome refraction is of value but really is not to displace the use of cycloplegia. May I give as a reference my editorial in the *American Journal of Ophthalmology* for November 1932 in which I have discussed the subject from the standpoint of physiologic optics.

Children's Sleep A Series of Studies on the Influence of Motion Pictures Normal Age Sex and Seasonal Variations in Motility Experimental Insomnia the Effects of Coffee and the Visual Flicker Limens of Children By Samuel Henshaw Professor of Experimental Psychology Ohio State University Vernon J. Miller Instructor in Psychology Bowdoin College and Dorothy P. Marquis Cloth 11c \$2 1p 212 with 31 Illustrations New York The Macmillan Company 1933

This monograph offers extensive quantitative data on the sleeping habits of children from 6 to 18 years of age. The work represents a part of a larger and related group of investigations of the influence of motion pictures on children sponsored by the Payne Fund of New York. During 347 nights, 170 children of both sexes were observed. These children in groups of twenty, slept in single beds each fitted with an electrical device which recorded the changes in posture made by the sleeper minute by minute throughout the nine hours stay in bed each night. Each group of twenty children remained in the experimental beds about fifty consecutive nights. The records include 6650 child nights of sleep. It represents the most comprehensive study of this nature thus far reported.

First a satisfactory norm or standard sleep pattern for the various ages, sex groups and seasons of the year was determined. This was compared with the sleep patterns obtained after the children saw various types of motion pictures in a typical neighborhood theater. Data also illustrate the variations in sleep motility with the season, the effect of drinking coffee and coffee substitutes at the evening meal, the effect of loss of sleep and impending illness, and a study of the limens of critical frequency for visual flicker in children of various ages. Enough of the observations are tabulated or given in graphic form to indicate the manner of arriving at conclusions. The monograph includes a summary of previous work on the problem of sleep in childhood and a bibliography of 255 titles on the general aspects of the problem.

Some of the conclusions are as follows: Temperature and relative humidity are not important factors in influencing hourly sleep motility. Younger children are quieter sleepers than older ones. The least motile and most recuperative sleep is indulged in during the first half of the stay in bed especially from thirty minutes to one and one half hours after retiring. Seeing some movie films does induce a disturbance of relaxed recuperative sleep, especially in the first half of the night in children, to a degree which if indulged in with sufficient frequency, can be regarded as detrimental to normal health and growth. For certain highly sensitive or weak and unstable children the best hygienic policy would be to recommend very infrequent attendance at carefully selected films. Children below 10 years of age show relatively less influence. The maximal effects seem to occur at about the age of puberty. The movie influence is not always limited to the night immediately following the viewing of the film.

The effects of the loss of sleep in children extend into several nights following the deprivation period and are reflected in the postdeprivation curves, whereas practically all investigators report that a single night is sufficient for complete recovery from the effects of insomnia periods lasting as many as 115 hours in the case of adults. All children show significant reductions in mean hourly motility as a result of the loss of a third of the usual night's sleep over a period of from three to five nights. This effect is comparable to the effect of a certain soporific drug (phenobarbital).

Frequent loss of sleep in amounts equivalent to one third of the normal ration occasioned particularly by late retiring, will almost certainly lead to disturbances in conduct and to physical conditions detrimental to health in children. Younger

children and children of weak constitution or nervous temperament will show these effects in the greatest degree.

So far as motility may be taken as an index of recuperative sleep, coffee does not have the consistently detrimental effect on the sleep of all children that it is generally assumed to have. Individual differences in susceptibility to the influence of coffee are so great that it is impossible to generalize regarding the extent or direction of its effects on children of the same sex or the same age. For some children coffee affects sleep motility during the first one to three hours of sleep for others during the middle of the night, and for a few children it seems to raise or lower the general level of the motility curve throughout the night. The fact that Kaffee Hag seems to produce a greater increase in motility than coffee for some individuals, would indicate that the extent of the effect is not a direct function of the amount of caffeine in the two beverages. For some individuals there can be little doubt that coffee causes increased motility in sleep to a considerable extent (in some cases doubled for the first part of the night), while in other children of about the same age and weight no appreciable difference is noted. Parents who would strongly protest against their young children ingesting from 0.25 to 0.4 Gm of caffeine between the hours of 6 and 9 p. m. nevertheless permit attendance at motion pictures whose effects on sleep motility may be as great as or greater than that of coffee and possibly more lasting in influence.

The critical frequency limen for both sexes of all ages is sufficiently low, so that the present rate of motion picture projections should not result in the perception of flicker and should therefore not be taken to indicate that children suffer distress from flicker in the motion picture theater or that the restlessness in sleep following the motion pictures was induced by this form of visual stimulation.

L'exploration fonctionnelle de la rate. Diagnostic et traitement des syndromes spléniques. Par Ed. Benhamou, médecin des hôpitaux d'Alger. 14p. 11c \$0 francs. Pp 215 with 10 illustrations. Paris. Masson & Co. 1933.

The author approaches the study of the various diseases associated with splenomegaly as one who has had much experience in tropical diseases. He calls attention to the fact that the work of contemporary physiologists and clinicians has enlarged the scope of investigation concerning the functions of the spleen and he devotes much attention to the application of physiologic methods to clinical diagnosis. He classifies diseases of the spleen according to three syndromes: those in which there is a disturbance of the reservoir function; those in which there is an abnormal degree of hemolysis; and those in which there is abnormal destruction of platelets. After calling attention to the conception of a closed circulation through the venous sinuses of the spleen and an open circulation by way of the reticulo endothelial tissue of the splenic pulp, he sets forth his own and reported experiences with respect to the value of injecting epinephrine in the demonstration of alterations of the reservoir function of the spleen. Roentgenograms, and erythrocyte and platelet counts made before and after the injection of 1 cc of 1:1000 solution of epinephrine, he believes give information that is valuable in diagnosis. Following the injection of epinephrine the platelets were found to increase in number within five minutes and the erythrocytes in ten or fifteen minutes. In hemolytic icterus an increase in the number of reticulocytes was noted. He believes that accurate results can be obtained only by having the patient at absolute rest for one hour preceding the test with epinephrine. Normal contractility of the spleen usually is lost in cases of splenic anemia and of Banti's disease, whereas it is present in hemorrhagic purpura, hemolytic icterus and certain other diseases. The author pays considerable attention to the value of ligation of the splenic artery in cases in which splenectomy might be associated with excessive risk. The spleen undergoes atrophy after ligation of the splenic artery, but adhesions are likely to become more dense, consequently he advises that ligation of the splenic artery should not be done when splenectomy may be necessary later. He believes that there are certain cases of hemorrhagic purpura in which operation must be performed during the acute stage and in which ligation of the splenic artery may be preferable to splenectomy. The author's discussion of the diagnosis and treatment of diseases associated with splenomegaly

does not differ greatly from treatises that have been published in English. Probably because of his experience the discussion of malarial splenomegaly is extensive and the existence of parasitic disease is always under consideration in connection with the diagnosis in any given case. The subject matter is logically arranged, illustrations are plentiful, there are many excellent tables of differential diagnosis and a bibliography of 299 references and an index are appended.

Dynamo Biology By Arthur O. Baker. John Adams High School, Cleveland and Lewis H. Mills, Glenville High School, Cleveland. Edited by William L. Connor, Chief, Bureau of Educational Research, Cleveland Public Schools. Cloth. Price \$1.72. Pp. 722 with illustrations. Chicago: Rand McNally & Company, 1933.

If the prime purpose of education is to fit the individual to meet the problems of life, this high school textbook should be useful. In comparison to the massed accumulation of details and facts combined with moralistic interpretations, which an older generation was required to study under the guise of biology, this book reads almost like a novel. The various phases of biologic phenomena are interpreted in terms of everyday living, whether in the plant or the animal kingdom. For instance, in the discussion of microscopic forms of life, the opportunity is taken to present pertinent facts concerning the spread and control of pathogenic bacteria, personal and community hygiene and the part played by the family physician in maintaining health. Several playlets are given, one of which deals with quackery and patent medicines. The information concerning digestion and nutrition is concise and accurate and for clarity might well be recommended to those groups of our population who are inclined to follow visional dietary fads. The chapters on reproduction escape the prudishness so often found in textbooks of this nature, yet are sufficiently conservative as not to offend the most sensitive individuals. Numerous photographic reproductions, drawings and diagrams accompany the text, and at the end there is an extensive glossary.

Some Thoughts of Asthma By A. I. D. Cameron, M.B., Ch.B., Physician to the Sherwood Park Clinic and Spa, Tunbridge Wells. With a foreword by Kenneth Playfair, M.A., M.B., B.Ch. Cloth. Price \$2.75. Pp. 178 with 12 illustrations. Bristol: John Wright & Sons Ltd., 1933.

This small monograph dealing with asthma of the bronchial type is apparently based on fifteen comparatively recent cases, in thirteen of which recovery had occurred at the time the book was written. It enthusiastically advocates the method of treatment championed by Haseltine and LaForge in the United States. Asthma is looked on as due to a combination of intestinal autointoxication, disease of the ethmoid sinuses and an irritable nervous system. The treatment is by repeated colonic flushings and diets for the intoxication and Dowling's mild silver protein packs (with or without surgery) for the ethmoid disease. No special mention is made of treatment of the irritable nervous system. The book is full of assertions with no experimental data to support them. It condemns the studies of the large majority of specialists in this field as being unnecessary and practically useless. The book praises the work of Barber and Oriel, work that has been condemned by leading American and British investigators. The book adds nothing to present knowledge. It would be interesting to know how these fifteen patients after five years of treatment have fared.

Physiology and Anatomy By Estlin M. Crelshelmer, B.S., in Education, M.A., Ph.D., Associate Professor of Physiology, the University of Minnesota, Minneapolis and Raymond F. Blount, B.S., M.S., Ph.D., Instructor of Anatomy, the University of Minnesota, Minneapolis. Second edition. Cloth. Price \$3. Pp. 697 with 401 illustrations. Philadelphia & London: J. B. Lippincott Company, 1933.

This volume occupies a prominent place in the extensive series of nursing manuals sponsored by the publisher. The task the authors have set themselves is a pretentious one indeed, that of encompassing in a little over 600 pages of text the essential features of the fields of anatomy and physiology. Considering the limitations of space and style necessarily imposed in a manual of this sort, the result is commendable to a surprising degree. The faults and errors are largely those of detail. Repeated excursions have been made into the realms of therapeutics of immunology and even of diagnosis, often thus appearing to detract from the work chiefly because it is fre-

quently not evident that such material is intended to be merely illustrative. The comparison of bodily organization to that of a high school is but a variant of the many hackneyed similes so commonly, and unnecessarily, employed by popular writers. The statement that the reaction of muscle is neutral to litmus does not make it clear that litmus is of little value in measuring the range of hydrogen ion concentration in normal tissue. Caput medusae is indicated as a sign of portal obstruction, while hemorrhoids are not mentioned in this connection. Water loss from the body is emphasized as occurring by insensible perspiration and by urination; the roles of expired air and feces are neglected. The section on endocrinology is far from adequate, particularly that dealing with the pituitary and with the sex hormones. The choice of the trade name 'pituitrin' for the 'hormone of posterior pituitary' when there is a pharmacopoeial name for the identical extract, is particularly poor, similarly the arbitrary choice of one of the many appellations (i.e. "cortine") that have been applied to the active principle of the suprarenal cortex is hardly warranted in a textbook, particularly when the name here adopted has received no general recognition. While these shortcomings detract considerably from the work, this is nevertheless a significant addition to the educational armamentarium.

Over cylinders en eiwit in urine [Casts and Albumin in the Urine] Proefschrift ter verkrijging van den graad van doctor in de geneeskunde aan de Rijksuniversiteit te Groningen op gezag van den rector magnificus Dr. A. G. Roos, hoogleraar in de faculteit der letteren en wijsbegeerte tegen de bedenkingen der faculteit der geneeskunde in het openbaar te verdedigen op vrijdag 8 Juli 1932 des namiddags te 4 uur door Leopold Veyler. Paper. Pp. 114. Assen: Van Gorcum & Comp. N.V. [n.d.]

The author has studied clinical conditions that are associated with cylindruria and albuminuria and has attempted to determine the mode of origin of these products in the urine. He has observed albuminuria and casts in such diverse clinical conditions as diabetic coma, chronic nephritis, hunger acidosis, icterus, epileptic seizures, physical exertion in sports, cardiac asthma and after the ingestion of ammonium chloride, calcium chloride and sodium salicylate. He finds that the hydrogen ion concentration factor is the common denominator in all these conditions, when the pH falls below 5 there is an increase in the albuminuria and cylindruria. The granular casts are not fragments of degenerated renal epithelium, as has been previously supposed, but consist of coagulated albumin with uric acid crystals. Whenever the urine becomes acid, the hydrogen ion concentration of the kidney cells is increased and globulins as well as albumins pass into the urine. Globulins have the property of flocculation at their iso electric point. In the urine this point is reached with a pH of 4.8. This is precisely the pH of the urine in which occurred the greatest amount of albumin and casts. The author concluded that the excretion of a very acid urine is associated with albuminuria and cylindruria. The presence of casts is no indication of renal damage.

Post Operative Treatment By George Sanford Foster, M.D., Surgeon to the Lucy Hastings Hospital, Manchester, N.H. Forewords by Horace Binney, M.D., Professor of Surgery, Tufts College, and John C. Rommel. Cloth. Price \$5. Pp. 323 with 18 illustrations. Boston: Christopher Publishing House, 1933.

In writing this book the author has reviewed his notes on the postoperative care of his patients. He has placed emphasis on the daily attention to details by the surgeon. This seems somewhat at variance with the routine treatment as outlined, since daily observation should permit a wider flexibility in the care of such conditions. The care needed after most of the standard operations in the different regions of the body is discussed in separate chapters. There is considerable repetition which may be excusable. Most surgeons will disagree with the routine confinement of almost all operative patients in bed for twenty-three days. The exceptions are the prostatectomy patients, who are up on the fourth day. One would expect that the advantages of being up early might also apply to other patients in advanced years after other operations. The routine use of gauze and rubber tube drains is not adopted in most hospitals. Gauze is now rarely used except for hemostasis. Rubber tubes are usually now split or covered as in the cigaret drains in order to lessen pressure rather than having free gauze around them. The routine use of cathartics such as mild mer-

curous chloride and castor oil, on the third day after operation, has been abandoned for a long time in most hospitals. No doubt exists that many useful hints have been made in the postoperative comfort of the patient. However, it is doubtful whether the routine adoption of all the author's practices in his own hospital would be equally desirable in others.

Le sinus carotidien et la zone homologue cardio aortique. Physiologie, pharmacologie, pathologie clinique. Par C. Heymans, professeur de pharmacologie et de pharmacodynamie à l'Université de Gand, J. J. Bouckaert, professeur de thérapeutique générale à l'Université de Gand et P. Regniers, agrégé de l'Université de Gand. Papier. Prix 50 francs. Pp. 334 with 127 illustrations. Paris: G. Dolin & Cie, 1933.

In 1932 THE JOURNAL (February 27, p. 761) reviewed a brochure in German by Eberhard Koch on the same subject matter. The present volume, in French, by leading experimenters in this interesting field, correlates the observations of all workers, the literature of which since 1923 alone covers twenty-five pages. Koch's monograph did not contain as large sections on the pharmacologic, clinical and pathologic aspects of the subject. Many clinicians probably are not yet familiar with the automatic regulation of blood pressure, respiration and other physiologic processes of the body by sensory impulses arising from intra-arterial pressure changes in the carotid sinus region, aortic arch and most probably also in blood vessels of other parts of the body. The thinking physician will want to know about these physiologic mechanisms because of their interest and because of the possible clinical states arising from malfunction of these mechanisms. In short, the clinician will find this book [also] of practical interest and significance in his daily work.

Oral Surgery. By Sterling A. Mead, D.D.S., M.S., B.S., Professor of Oral Surgery and Diseases of the Mouth and Director of Research, Georgetown University Dental School. Cloth. Price \$12.00. Pp. 1087 with 463 illustrations. St. Louis: C. V. Mosby Company, 1933.

This is a large volume covering many subjects, and probably it is admirably suited to the author's intended purpose. He states that there appears to be a need for a book on oral surgery containing subject matter especially selected and arranged for instruction of the undergraduate dental student yet sufficiently concise and systematized as to permit of accommodation to the limited time of the college curriculum. The importance of minor oral surgery is not always sufficiently recognized in our dental schools, in many cases an attempt is made to teach major studies to those who would do well to grasp the minor ones, also this field of minor oral surgery is the only one into which the average dental practitioner will enter. A somewhat less general title might have been used.

Prophylaxie de la tuberculose. Applications en Europe. Par Etienne Burnet, de l'Institut Pasteur. Papier. Prix 65 francs. Pp. 375 with 25 illustrations. Paris: Masson & Cie, 1933.

This is a thoughtful work based on an abundance of investigation. While the data, except for occasional pertinent references to this country, have been collected only in Europe and the recommendations are for European application, the assemblage will prove of great value to American physicians and public health workers. The author is to be commended for the balance he has preserved. It would not be surprising if a French author discussing the prophylaxis of tuberculosis emphasized preventive vaccination with BCG above everything else. Burnet, however, devotes but eight pages to this, and while his comments are entirely favorable they are also conservative. The monograph is divided into two parts, the principles underlying the prophylaxis of tuberculosis and a summary of the organization of the antituberculosis campaign in different European countries. The historical consideration devoted to the decline of tuberculosis will be found of much interest. Burnet points out the well known fact that the decline in tuberculosis mortality in general began long before the modern period of bacteriology and hygiene. The curve of decline varies for different countries and for individual groups in a single country. In some countries the decline has barely commenced. Others are well down the curve. Industrialization, which initiated the original rise, favors the decline 'when it reaches the stage of social hygiene.' Up to a certain point general social trends may be expected

to depress the tuberculosis rate, but there is a critical point, which Burnet fixes at a tuberculosis mortality rate of 80 per hundred thousand where spontaneous decline ceases and specific antituberculosis measures are necessary to continue the rate of fall. The key structure for antituberculosis control Burnet repeatedly emphasizes is the dispensary. The methods used in the dispensary and the adjuncts employed, such as sanatoriums, preventoriums and special schools, will vary with the local problem but the campaign must center in the dispensary. Emphasis should be laid on removing the bacillus carrier from opportunity to infect others, and as has been stressed in this country in recent years, this should be the chief function of the sanatorium. In this connection attention is called to the possibilities of mass application of pneumothorax, a procedure long valued as an individual therapeutic measure but now recognized as an epidemiologic weapon of great possibilities. Part II will be found useful as a source of knowledge of the specific measures employed in the different European countries.

Studies on Blood Sugar and Glycosuria in Exophthalmic Goiter. By William Thune Andersen. Paper. Pp. 206 with 16 illustrations. Copenhagen: Levin & Munksgaard, 1933.

The much discussed question of hyperglycemia and glycosuria in exophthalmic goiter and the relation between this disease and diabetes mellitus is the subject of this small monograph translated from the Danish. The author reviews the literature and reports his detailed observations on thirty-one patients with exophthalmic goiter and two patients with diabetes one with exophthalmic goiter and the other with myxedema. Although there was little difference from the normal in the fasting blood sugar levels, most of the patients gave sugar tolerance tests slightly higher and more prolonged than normal. The sugar excretion thresholds were slightly lower than normal, though no cases of typical renal glycosuria were found. After thyroidectomy, the sugar tolerance test was usually unchanged, while the kidney threshold rose slightly. The relatively frequent occurrence of glycosuria in exophthalmic goiter is therefore attributable to the tendency to alimentary hyperglycemia coupled with the slightly lowered kidney threshold. The text is fully illustrated by tables and graphs and detailed case reports of all the material are appended. The bibliography is international in character. The volume should be of interest to the specialist in this field.

The Mechanism of Nervous Action. Electrical Studies of the Neurons. By E. D. Adrian, M.D., D.Sc., F.R.S., Foulerton Research Professor of the Royal Society. The Eldridge Reeves Johnson Foundation for Medical Physics. Cloth. Price \$2. Pp. 103 with 35 illustrations. Philadelphia: University of Pennsylvania Press. London: Oxford University Press, 1932.

This constitutes the Eldridge Reeves Johnson Foundation lectures for 1931. Its author, a Nobel prize winner with Sherrington, presents in simple language much of his own research and that of his associates on the physiology of nervous action. After an outline of the history of electrophysiology, two chapters are devoted to the action of the sense organs and to Discharges in motor nerve fibers are next discussed and the book closes with an account of the activity of nerve cells. Although the book contains results of fundamental research on nerve action, it will probably cause a ripple of enthusiasm in but 1 per cent of busy practitioners into whose hands it might fall.

Trois fondateurs de la médecine moderne. Pasteur, Lister, Koch. Derniers écrits. Par Elie Metchnikoff. Préface de M. le Dr. Et. Burnet, directeur adjoint de l'Institut Pasteur de Tunis. Papier. Prix 10 francs. Pp. 196. Paris: Librairie Félix Alcan, 1933.

The main part of this book consists of the essay Metchnikoff wrote in Russian in 1915 about the work and personalities of Pasteur, Lister and Koch, whom he regards as the founders of modern medicine. Here are interesting personal reminiscences. This essay, a model of luminous exposition gives a stirring introduction to the microbic era and its great pioneers. The rest of the book contains Metchnikoff's last writings (1) his answer to Roux's letter (also reproduced) on his seventieth birthday, and in this answer he discusses his then favorite topic, old age (2) his article on the death of the mulberry butterfly, a chapter in thanatology, from the *Annales*

de l'Institut Pasteur 29 477 1915, and (3) a chapter on the sexual function prepared for a projected book on the sexual question. These writings illustrate well Metchnikoff's views and ideals, which are discussed understandingly in the preface by Etienne Burnet of the Pasteur institute in Tunis

Medicolegal

Malpractice Implied Partnership, Liability of Individual Partners—The Northern Pacific Hospital, at Missoula, Mont., is operated principally for the benefit of members of the Northern Pacific Beneficial Association. Other patients are admitted, however as pay patients. The medical staff of the hospital consists of Dr George T Jennings, Dr T Haas and Dr A R Foss. Each physician has a private office in the hospital, where he is permitted to treat private patients. Each is entitled to use all the equipment of the hospital, including the services of the nurses, for which privilege the three physicians pay jointly \$60 a month.

The plaintiff in this case, who was not a member of the benefit association, called on Dr Haas for treatment and he referred her to Dr Foss. After examining her, Dr Foss directed her to go to the "surgery" of the hospital, for irrigations of the bladder with a solution of boric acid, on each of three successive days. The nurse in charge of the "surgery" was instructed by Dr Foss to do these irrigations. On the third day, by mistake, she irrigated with a solution of bichloride of mercury. For resulting injuries, the plaintiff sued the Northern Pacific Railway Company, the Northern Pacific Beneficial Association, and the three physicians named above. The trial court directed verdicts in favor of every defendant, and the plaintiff appealed to the Supreme Court of Montana.

In directing a verdict for the Northern Pacific Railway Company and for the Northern Pacific Beneficial Association, said the Supreme Court the trial court did not err. The physicians in this case constituted the staff of the hospital, but they were also private practitioners, and in their private practice they were independent of the beneficial association and the railroad company. Their arrangement for the use of the hospital, with its equipment and nurses, was no more and no less than a leasing of the hospital, fully equipped, for their private practice.

If Dr Foss or the physicians associated with him are liable for an act or omission of a nurse, continued the court, it is under the doctrine of respondeat superior. The physicians contended that nursing is a profession in itself and that the ordinary principles governing the relationship between master and servant do not apply. But the mere fact that an assistant to a physician is a member of the same or of a similar profession, the court pointed out does not take the employer and employee out of the operation of the rule of respondeat superior. If a physician sends another physician to treat a patient and the substitute is accepted by the patient, the physician is not liable for the independent acts of the substitute. But when a physician retains complete control and renounces no part of his functions as sole physician, and delegates to another only the manual administration of the prescribed treatment, the relation of principal and agent exists, whether the person administering the treatment is a layman, a physician or a nurse. In this case it is clear, said the court that the nurse was the agent of Dr Foss, in irrigating the plaintiff's bladder and for the nurse's negligence he may be held liable.

The liability attributed by the plaintiff to Drs Jennings and Haas was predicated on the contention that they and Dr Foss were operating as a partnership and that the act of one within the scope of the partnership business was the act of each and all. That there was any such partnership was denied by the physicians. The existence or nonexistence of a partnership said the Supreme Court, is a question of fact, to be determined by an examination of the relationship among the parties. If the facts bring the arrangement within the definition of a partnership the parties cannot escape liability incident to that relationship by saying that no partnership exists.

These three physicians were drawn together in the same building by common employment as the staff of the Northern Pacific Hospital. Not having all their time taken up, they agreed, either expressly or impliedly, to treat as patients of the firm all persons who came to any one of them and whose condition was such as to require attention in the hospital for a day or more, and to divide the fees equally. Each was permitted to represent himself as a member of the firm of "Jennings, Haas & Foss." For services rendered, bills were submitted on a billhead bearing the legend "Doctors Jennings, Haas & Foss." By a secret, informal agreement, it was understood, however, that if a patient did not require hospitalization he became the individual patient of the physician receiving the patient and that the fee was his. A partnership agreement, continued the court, need not be in writing and may be express or implied. To prove the existence of a partnership, it is not necessary to prove its elements by direct evidence, a billhead, such as was used in the present case, purporting to show the names of the partners, is competent evidence on this question. To hold two or more persons liable as partners, it must be shown that they consented to become partners, acted as such in carrying on the business, divided the profits, and occupied the interchangeable position of principal and agent. Where the business is such as to require the use of property, there must be a community of title. The evidence was sufficient, said the court, to warrant the finding that the three physicians were partners.

The plaintiff testified that she called on Dr Haas because he was a member of the firm, and she expected to receive the benefit and experience of the firm. If the jury accepted this uncontradicted testimony, said the Supreme Court they might well find that the plaintiff did in fact employ, and was a patient of, the firm. Any secret limits on the authority of one of the firm or on the division of compensation, not known to the plaintiff, could not affect her right to look for damages for her injuries, to those in whom she placed her trust. Secret limitations on the authority of a partner are valid as between the partners, but a third party, if such limitations are not made known to the public, may deal with the firm on the presumption that any act within the general scope of a partner is within the authority of the partner with whom he deals.

The question whether the plaintiff was the patient of the firm or of Dr Foss alone was for the jury to determine, said the Supreme Court. If she was the patient of the firm, then the nurse was the agent and employee of the firm and all the physicians were responsible for the injuries caused by her negligence, though no one of them was himself negligent. The court therefore reversed the action of the trial court in directing a verdict for the three defendant-physicians and remanded the case for a new trial.—*Simons v Northern Pac Ry Co (Mont)*, 22 P (2d) 609.

Libel Distribution of Articles from Medical Journals

—The plaintiff, Julia La Salle Stevenson, is described in the record as a "professional teacher of educational psychology" and a lecturer on personality, beauty and charm. She lectured on such subjects as "The Cause of Old Age," "How to Stay Young," "Rejuvenation Through Autosuggestion," "Eating Your Way Back to Health," "Forces Within You and How to Use Them" and other subjects of like nature. The defendant, as editor of *Southern Medicine and Surgery*, the official organ of the Tri-State Medical Association, published articles concerning the plaintiff wherein she was charged with being a faker, a teacher of fantastic isms and a member of fantastic cults. The articles charged also that the plaintiff advertised in "McFerrin's" health bulletin, whose columns, it was stated, "were patronized by either quacks or faddists, and doubtless 'Dr' Stevens [sic] feels at home among this class." Subsequently, the defendant sent copies of these articles to the president of the Asheville Normal and Teachers' College and as a result the plaintiff lost the opportunity of delivering lectures before the student body of that institution. Lecturer Stevenson then sued the defendant for libel. The trial court held that the original publication of the alleged defamatory articles in *Southern Medicine and Surgery* was privileged, but for the subsequent publication—the mailing of the articles to the president of the college—a judgment was rendered for the plaintiff.

The superior court of Buncombe county upheld this judgment and the defendant appealed to the Supreme Court of North Carolina.

The defendant contended that the subsequent publication was at least qualifiedly privileged and therefore both falsity and actual or express malice must be shown to establish liability. In actions for libel said the Supreme Court, it is not necessary that particular ill will or malice should exist toward the plaintiff. Malice in this connection is defined as any indirect and wicked motive which induces the defendant to defame the plaintiff. If malice be proved, the privilege attaching to the occasion is lost at once. The privilege attaching to the occasion in the present case continued the court and the court doubted if any attached was at once lost on the showing of malice. The plaintiff contended that in mailing the letter the defendant was not actuated by any desire to protect the public but was possessed of a spirit of unkindness and sent the letter "with intent to injure her." On the other hand, the defendant contended that he was merely interested in the medical profession, that he acted in good faith with no ulterior motive and that he mailed the letter only in the interest of the public good. These contentions, the court said were fully given to the jury and it was for them to say which contention the evidence supported. The jury was instructed that if the subsequent distribution was in good faith why then that would end the case. The jury must have found said the court that the articles were false and that they were distributed maliciously or for no good purpose. The court considered it unnecessary to decide whether the occasion was in fact unprivileged as the plaintiff contended or qualifiedly privileged as the defendant asserted. Undoubtedly the publication was actionable continued the court it untrue and not privileged for it tended to expose the plaintiff to ridicule or scorn and was calculated to injure her in her calling or profession. The evidence in this case was quite sufficient concluded the court to carry the case to the jury. The judgment against the defendant was therefore affirmed.—*Stevenson v. Northington* (N. C.) 169 S. L. 622.

Faith Healing as the Practice of Medicine—Royal Miller, an Iowa farmer, undertook to cure the sick who desired his services. For years his neighbors and friends called him "Doc." For a time he carried the designation "Dr." in front of his name in the telephone directory but on being advised that the use of that appellation was improper, he discontinued it.

Section 2538 of the Code of Iowa 1931, declares who shall be deemed to be engaged in the practice of medicine and surgery, namely:

1. Persons who publicly profess to be physicians or surgeons or who publicly profess to assume the duties incident to the practice of medicine and surgery.

2. Persons who prescribe or prescribe and furnish medicine for human ailments or treat the same by surgery.

3. Persons who act as representatives of any person in doing any of the things mentioned in this section.

The laws of Iowa do not exempt a faith healer from the operation of the laws regulating the practice of medicine, requiring a license as a condition precedent to practice.

The state brought an action to enjoin Miller from practicing, alleging that he had been and was engaging in the practice of medicine and surgery without a license that he had assumed and was assuming the duties of a physician and surgeon, that he had been and was diagnosing, prescribing for and treating diseases, and that he had assumed other incidental duties of a physician and surgeon and was maintaining an office and had advertised as "Dr. Royal Miller." The district court Cerro Gordo county denied the injunction and the state appealed to the Supreme Court of Iowa.

The Supreme Court attached no weight to the fact that Miller was called "Doc." by his friends and neighbors. There are many kinds of doctors. Besides, it is a common practice to use nicknames. Often druggists clerks are called doctors, often some well known town character not versed in the law is called "Judge" and some county school teachers are called professors. Miller said the court, did not publicly assume the duties of a physician and surgeon. At no time did he make physical examinations or diagnose the ills of his patients or prescribe medicine. He told his patients not that he would

cure them but that he would help them if he could. His treatment was the laying on of his hands or at most a slight massage at the back of the neck and head. He made no charge but accepted voluntary offerings. He had no office but met his patients by private arrangement at his home or at a room at a hotel. He had no advertisement on his door and published no advertisements in the newspapers. He had no cards. He never claimed privately or publicly that he was a physician and surgeon. He told his patients that he did not know where he got his power, unless he got it from the Savior and that through faith one could be healed. Frequently when he saw that he was doing no particular good he would send his patient to a physician and surgeon.

There are said the Supreme Court a great many people who believe, and certain churches that teach that through faith one can be cured. Certainly there is nothing in the statutes of this state that would permit the courts by injunction, to bar the exercise of that power. The court affirmed therefore the judgment of the court below refusing to grant the injunction.—*State v. Miller* (Iowa) 249 N. W. 141.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Bachman Intradermal Reaction in Human Trichinosis

Kilduffe utilized the Bachman skin test in the study of thirty-three persons exposed to trichinosis from which he concludes that 1 The demonstration of eosinophilia is not only technically simpler than the demonstration of the skin test but always feasible whereas the skin test requiring an antigen difficult to prepare is feasible only when the antigen is available 2 In point of delicacy and constancy of appearance eosinophilia serves as a reliable index of trichinosis in the

human being 3 The Bachman skin test in the study of human trichinosis presents no practical advantages over the demonstration of eosinophilia

Effect of Injections of Solution of Pituitary on Blood Pressure—Moffat gave 1 cc of solution of pituitary by intramuscular injection to sixty-two persons and observed the blood pressure at nine intervals in from two to sixty minutes. No constant changes in blood pressure were observed. In a few persons there was a marked change in the blood pressure, but this was as often downward as upward. In the majority there was little or no change. The general trend of the blood pressure was except for a slight transient rise immediately following the injection downward rather than upward. This downward trend was more marked in the systolic than in the diastolic pressure and resulted in a slight but constant decrease in pulse pressure. In general, the higher the initial pressure, the greater was the fall following the injection of solution of pituitary.

Blood Sugar Curves in Mental Disorders—Katzenbogen and Friedman-Buchman studied the carbohydrate metabolism in 116 psychotic patients as tested by the blood sugar tolerance curves. These included thirty-one cases of merergasia (psychoneurosis) fifty of thimerergasia (manic-depressive psychosis) six of which were in the manic state) twenty-eight of parergasia (schizophrenia) and seven of anergasia (organic psychosis). The blood sugar curves were evaluated by the intensity of the alimentary hyperglycemia (following the ingestion of 50 Gm of dextrose), by the extension of the glycemic reaction over a period of two hours (hyperglycemic index) and by both the height and the extension of the curve combined (hyperglycemic area). Abnormal curves were obtained in each psychotic group in merergasia, 64 per cent in hypothimerergasia 72.9 per cent and in parergasia 60.7 per cent when the curves were evaluated by the climax of the hyperglycemia. When estimated by the hyperglycemic area, the values were 62.5 per cent 79.2 per cent and 72.7 per cent, respectively, but in anergasia 100 per cent judged by both methods of evaluation. The abnormal curves show similar characteristics in the four psychotic reaction types. In each of them high and broad curves in which the hyperglycemic peak is moderately high but the glycemia remains above the fasting level two hours after dextrose was taken and curves in which the markedly high hyperglycemic reaction goes together with the return of the glycemia to the fasting level at the end of the period

of two hours after the administration of dextrose were found to be representative. The authors believe that the apparently similar disturbance of the carbohydrate metabolism in the different psychotic reaction types may be related to a common denominator, that is, affective disorder. Thus the abnormal blood sugar curves in their patients are considered as physiologic accompaniments of psychobiologic reactions.

Relation of Thyroid, Suprarenals and Islands of Langerhans to Malacic Diseases of Bone.—Golden and Abbott examined the roentgenograms in 110 cases of hyperthyroidism, fifty-one of hypothyroidism and fourteen of Addison's disease, and sixty roentgenograms of adult diabetic patients. They conclude that hyperthyroidism produces an abnormal elimination of calcium, the mechanism of which is not understood. It seems to be frequently associated with a decalcification of the bones demonstrable on the roentgenogram by suitable comparison with the normal, which is so slight as to be of little if any importance. In rare cases the decalcification of the bones may be extreme. Its appearance, however, is not characteristic of thyrotoxicosis. In cretinism and infantile myxedema there is a widening of the cortex of the long bones without loss of calcium. Hypothyroidism in adults is apparently associated with no greater incidence of decalcification of bones than that which might be encountered in any group of patients of the same age. Although suprarenal secretion directly or indirectly influences calcium metabolism and although the suprarenals may

be indirectly involved in a pluriglandular imbalance in certain cases of osteomalacia, the evidence does not seem to justify the assumption that decalcification of the bones results directly from disease of the suprarenals or dysfunction. Calcium metabolism is intimately linked with carbohydrate metabolism. The available evidence indicates that a calcium loss may take place in diabetes especially with acidosis. In children the disease may be associated with a decrease in the density of the bones on the roentgenogram, which in one case was so marked as to suggest osteomalacia. The question may be raised as to how much of this is of endocrine and how much of nutritional origin. Roentgen evidence of definite important skeletal decalcification in diabetic adults which can be attributed directly to the disease is lacking.

Familial Infection by *Endamoeba Histolytica*.—Mackie and Nauss present the history of a family of six of which four members were infected with *Endamoeba histolytica*. The source of the infection seems to have been the mother, who has had the direct care of the children and of the preparation of food. The children have not at any time been out of New York City. The history given by the father of constipation associated with mucus in the stools five years ago is suggestive of amebiasis and the negative examination cannot be accepted as indicating freedom from infection until more prolonged studies have been carried out. This is especially true in view of the demonstration of *Endamoeba coli* in his intestinal tract. If the father is eliminated as the original source, it is probable that the mother acquired her infection in the summer of 1931 when both parents visited in a small village where flies had easy access to human dejecta. The fact that the children have not been out of the sanitary area of New York City indicates that the spread through the family occurred probably as a person to person transmission.

Bromide Psychoses.—Levin establishes the diagnosis of a bromide psychosis on the following criteria: 1. The existence of a bromide intoxication as shown by the Walter-Hauptmann test. 2. The fact that the psychosis began after the patient had become intoxicated. 3. The fact that the psychosis clears up within a short time—generally from two to six weeks—after the discontinuance of bromides. The patient should be kept in bed until the intoxication has subsided. Fluids should be

forced If there is no nephritis, 4 Gm of sodium chloride should be given three times a day, the chloride ion facilitating the excretion of the bromide ion Patients who are restless should be given continuous baths The need of using only the least toxic hypnotics is especially urgent in bromide intoxication, poisoned as the patients already are, paraldehyde will suffice for the majority of them Cardiac stimulants should be given when indicated The author urges the following suggestions for the prevention of bromide psychosis 1 When contemplating the administration of bromides, the physician should seek to ascertain whether the patient is already getting bromides from another source 2 He should know whether the patient takes much or little table salt In the latter case he should be doubly cautious 3 He should not relax his vigilance just because the dosage he is giving is one that has proved harmless in the majority of his patients 4 When a nervous patient getting bromides grows worse the physician should promptly discontinue the drug unless he has good reason to believe that it bears no responsibility for the aggravation 5 When a patient has been taking bromides for a month or more, it is wise to discontinue them occasionally for a week or two An occasional Walter-Hauptmann test is the best way to make sure that the patient is not becoming intoxicated

Effect of Pilocarpine on Gastric Secretion—Meienberg and Brown studied the effect of pilocarpine on the various constituents of the gastric juice and compared the results with those obtained following histamine stimulation They observed that pilocarpine is a true stimulant of gastric secretion, its chief effect being an increased volume of gastric juice, the acid and pepsin secretions, however are also stimulated Histamine also stimulates the secretion of pepsin, and the values obtained are not explained by a process of washing out of the gastric crypts as suggested by some workers No definite evidence is obtained to support the opinion expressed by some experimenters that pilocarpine is a better stimulant of enzyme secretion than histamine The results are not sufficiently conclusive to say that either is a better stimulant for enzyme secretion than the other This also seems to be true in regard to the secretion of acid There is no appreciable difference in the effect of these two drugs on the secretion of total chlorides No untoward symptoms were noted from the use of pilocarpine in the doses given (0.5 mg for each 10 Kg of body weight), with the exception of slight nausea, which was experienced by one patient A definite increase in salivation was noted in practically all cases The estimation of total peptic activity during a given period would seem to be a better quantitative index of peptic secretion than a determination of the concentration of pepsin

Lobar Atelectasis as a Cause of Triangular Roentgen Shadows in Bronchiectasis—In their study of bronchiectasis particularly in reference to triangular basal shadows Warner

and Graham endeavored to determine the significance and cause of the shadows and have them produced experimentally They found that triangular basal shadows as seen in roentgenograms of the chest are diagnostic of bronchiectasis Their presence should always be taken as an indication for the injection of iodized oil to confirm this diagnosis They occurred in about 6 per cent of all cases of bronchiectasis The authors report two cases of bilateral triangular basal shadows Triangular basal shadows are caused in some cases at least and probably in all cases initially, by a lobar atelectasis of the bronchiectatic lobe They believe that the cause of this lobar atelectasis is the plugging of the terminal bronchioles by the swelling of the bronchial wall with an inflammatory exudate Lobar atelectasis produced in dogs by completely occluding the bronchi of the lower lobes caused typical triangular shadows due to the atelectatic lower lobe Atelectatic bronchiectatic lobes may occasionally be found on physical examination, such physical signs are diagnostic of bronchiectasis Bronchiectasis may occur in the absence of both fibrosis of the pulmonary parenchyma and pleural adhesions

Skin Lesions of Pellagra—Spies chose ten patients presenting the characteristic dermatitis of pellagra for his experiment and exercised extreme care to select those without neurologic involvement Each patient remained in bed throughout the experiment and was given a diet of corn starch and lactose amounting to 2,000 or 3,000 calories a day Two of six persons having stomatitis were unable to tolerate this diet and vomited frequently, the stomatitis and glossitis became worse rapidly, so the diet was discontinued As soon as the dermatitis of the eight remaining patients healed, they were given a high caloric, high vitamin diet In order to test this diet still further it was fed to six young albino rats The author found that persons having pellagra and tolerating a diet of lactose and corn starch show improvement of their cutaneous lesions This confirms and somewhat extends his previous observation that the dermatitis of pellagra improves while the patients receive a so called pellagra-producing diet He recommends that improvement in dermatitis be interpreted with great care before accepting it as an index either of efficacious treatment or of favorable prognosis It appears possible that the specific chemical substance related to the development of the dermatitis is not the same as that affecting manifestations of the disease in the gastro-intestinal or central nervous system

Otogenous Meningitis—Gatewood and Settel describe a case of fulminant meningitis in which the primary otitis media had regressed and was apparently well on the way to resolution when, with a sudden onset, signs of fulminating meningitis appeared, with recurrence of the pain in the ear and development of the characteristic stiffness in the back of the neck The patient died within twenty-four hours The markedly increased pressure of the cerebrospinal fluid, together with the opacity and the greatly increased cell count of the fluid, could mean only well established meningitis When one adds to this the presence in large numbers of *Streptococcus viridans* in the fluid, there is additional evidence of generalized septic leptomeningitis From their observations the authors conclude that various pathways exist by which infection may pass from the middle ear to the brain Extension by way of the blood vessels or lymph canals leads rapidly to a diffused meningitis Positive blood cultures are indicative of a hematogenous infection of the brain Their observations in their case pointed to the blood stream as the route by which the meninges were infected

Primary Malignant Neoplasms of Maxillary Sinus — Houser states that an absolute diagnosis cannot be obtained without securing a biopsy specimen. The method of choice is to perform a Caldwell-Luc operation under local anesthesia in cases in which the observations are suggestive of antral tumor. This permits inspection of the sinus, and the securing of biopsy material. If the interior of the sinus is negative for tumor, immediate closure is performed. In case the interior of the sinus has a suggestive but not definitely positive appearance, the wound is packed wide open. When the positive diagnosis is obtained, the patient receives roentgen therapy over the antrum and the cervical lymphatic channels as a preliminary procedure. In his series of twenty-one cases the author carried the dosage to the limit of cutaneous tolerance with high or low voltage roentgen therapy. The doses given to patients treated with high voltage therapy varied from 800 to 1600 roentgens per portal. The factors were 200 kilovolts, a distance of 50 cm., 4 milliamperes and a 0.5 mm. filter of copper. Some of the patients received in addition an erythema dose of radium delivered through a 3 cm. radium pack, the filter being equivalent to 3 mm. of lead. After operation radium was placed in the maxillary sinus; the dosage in this series ranged from 300 to 4,000 milligram hours. Four of these patients, or 19 per cent., are now living, one for thirteen years without signs of recurrence, one, five years, one, two years, and the other one one and one-half years. The treatment followed depended largely on the status of the lesion. Six growths when first seen, were so far advanced as to be considered inoperable. All the patients, however, regardless of the condition existing when they were first seen, were treated with roentgen radiation and radium. When pain was marked, avulsion of the sensory root of the trigeminal nerve was performed or if this operation was not considered proper, alcohol was injected into the second and third divisions. Radical removal of the upper jaw was performed in three; all had a recurrence and died within a year. In ten patients radical operation was performed on the maxillary sinus involved. Three of the patients operated on received electrocoagulation of the lesion at the time of operation.

Angio-Endothelioma of Bone with Hemothorax Due to Pleural Metastases — Warner and Singleton report a case of angio endothelioma of bone in which the symptoms were present for only five months prior to death from metastases arising from the primary malignant bone tumor. During illness the symptoms referable to the primary tumor were not severe; the whole picture was overshadowed by symptoms due to pleural

metastases which bled producing hemothorax and resulting in death from hemorrhage. The vascular character of the angioma was undoubtedly the cause of the massive hemorrhage. Therefore, in hemothorax due to tumor one should suspect some vascular tumor, such as angioma. However, this massive hemothorax obscured the underlying pathologic process and only after replacement pneumothorax could the metastatic sarcomatous nodules on the pleura be shown roentgenologically. Whether the patient's injury, a fall from a bicycle was the exciting cause of the primary tumor or merely called attention to a preexisting tumor is speculative. The onset of pain immediately after the injury would be in favor of a preexisting tumor. The presence of hemothorax from pleural metastases of a sarcomatous type accompanied by the presence of a primary malignant tumor of the bone led to the diagnosis of angio endothelioma of bone. It would seem from the necropsy confirmation of this diagnosis that in cases of true hemothorax from secondary sarcoma the possibility of a primary malignant bone tumor should be borne in mind.

Pneumonecstomy Preliminary Report of Operative Technique in Two Successful Cases W. F. Riehoff Jr. Baltimore — p. 390

Pneumonecstomy — Riehoff describes an operative procedure that has been successfully employed in two cases in which complete removal of the entire left lung was found to be necessary because of a benign and a malignant tumor, respectively of the left primary bronchus. For two weeks previous to operation the left lung was compressed by a gradually induced artificial pneumothorax, which finally brought about a complete collapse of that lung. Tribrom ethanol, 70 mg. per kilogram of body weight was given by rectum thirty minutes before operation, and nitrous oxide and oxygen was administered as a supplementary anesthetic. The position of the patient on the operating table was semirecumbent with the right side down. The trunk was rotated toward the right, to an angle of about 45 degrees; the left arm was raised over the head and the head of the table elevated to 45 degrees. An incision was made in the third interspace parallel to the third and fourth ribs and extending from the costal cartilages to the anterior axillary line. The fibers of the pectoralis major muscle were divided along their course. The internal intercostal muscles were cut directly across. The parietal pleura herniated up between the ribs as a result of the increased intrathoracic pressure and when it was incised the escaping air gave off a hissing sound. The third and fourth ribs were spread apart with a self retaining

retractor. The anterior approach was used. The pulmonary artery and veins were ligated. The pulmonary artery running in front was isolated by blunt dissection and clamped just midway between the reflection of the pericardium and the primary division of the artery. The proximal arterial stump was then ligated with oiled braided silk and the mouth of the vessel transfixed with medium waved silk. The superior and inferior pulmonary veins were then isolated in turn and transfixed with medium waved silk. In the first case the left primary bronchus was cut across with the scalpel and the lung removed from the chest. The cartilaginous rings of the bronchial stump were cut at various points in their circumference in order to do away with their springlike action which normally tends to maintain the patency of the bronchus. The bronchus was sutured with interrupted medium silk sutures, and the mucous membrane was approximated just as one would do in the suture of mucous membrane elsewhere. In the second case the technic was as described, but owing to the location of the tumor it was possible to cut across the first ventral or superior branch and then incise the primary bronchus diagonally. This left to be closed two openings somewhat smaller than if the primary bronchus had been cut across perpendicularly. There was but little loss of blood during the course of the operation. The pulse rate and blood pressure were unaltered. The ribs, which had been spread apart were reapproximated with number 2 silver wire and the pectoral muscles, subcutaneous tissue and skin were sutured with interrupted fine silk sutures. In both cases the chest was closed without drainage. The first patient had an afebrile and uneventful convalescence. The second patient has also had an uneventful convalescence with primary healing throughout. It is not necessary to perform a thoracoplasty at the same time as a pneumonectomy because the remaining lung will in uninfected clean cases obliterate the ensuing dead space. To prevent infection mass ligatures and cauterization of the bronchus should be abandoned. Individual ligation of the vessels and the minimal amount of injury to the bronchus in suturing permit primary healing of the bronchial mucous membranes.

Agglutination with Bacillus Typhosus.—The study of 4,000 serums by Gilbert and her associates has shown that the employment of macroscopic tests with two killed suspensions of typhoid bacilli, one to demonstrate the floccular or species-specific, and the other the granular or group-agglutinative properties, usually furnishes information of greater diagnostic significance than does the microscopic test with living culture. These observations are in general accord with the results reported by other workers. Apparently, agglutination in a 1:80 or higher dilution with an alcohol-treated suspension usually indicates that the patient has typhoid or an infection incited by a species allied to *Bacillus typhosus*, while a similar reaction with a formaldehyde treated suspension suggests one of three alternatives: that the patient has typhoid, has had the disease in the past, or has received typhoid vaccine. Both the granular and floccular types of agglutination have seldom been observed in high dilutions of serums other than those from typhoid patients.

Treatment of Irritable Colon with Sodium Ricinoleate.—Burger treated twelve patients exhibiting the symptoms that are attributed usually to an irritable colon with sodium ricinoleate. Prior to the institution of this treatment, these patients failed to respond to a bland diet and antispasmodics. He observed that the cases reported by Dorst and Morris had all been under treatment for a period of six months or longer. Some of the inconclusive results obtained with certain of the cases included in this series are reported after only three months of treatment and would probably respond to persistent therapy. The general results may be outlined as follows: There was a diminution of the pain and belching in the majority of the patients. The amount of flatus was diminished in five. Constipation was not affected. Mucus in the stools was appreciably lessened or disappeared in 50 per cent of the patients who showed this symptom. It is important to note that the patients who did not show clinical improvement during the treatment with purified sodium ricinoleate presented with one exception, definite gastric symptoms following the ingestion of the drug. This demonstrates the necessity for having more adequate enteric coating since the sodium ricinoleate if liberated in the stomach and acted on by gastric secretions gives rise to distressing symptoms. The skin sensitivity to organisms from the intestinal flora was reduced materially in nine out of ten cases. In two it was impossible to obtain sensitivity records at the end of treatment.

Hemolytic Streptococci Isolated from Hemorrhagic Smallpox.—Fisher believes that certain differences exist between the hemolytic streptococci isolated from blood cultures of fatal hemorrhagic smallpox and the pyogenic type of organism of scarlet fever, erysipelas and puerperal septicemia. Morphologically, the strains of streptococci from smallpox are similar to those isolated from scarlet fever, puerperal septicemia and erysipelas. Classification of the streptococci by means of their action on certain carbohydrates would place the organisms from smallpox and those from scarlet fever, erysipelas and puerperal septicemia in two distinct groups, based on the inability

of the latter to ferment lactose. Each of the controlling strains produced an acid reaction in litmus milk, while the strains from smallpox were all negative. The virulence for mice of organisms from smallpox is low, the usual fatal dose, after repeated passage, being about 0.1 cc. Agglutination tests with both homologous and heterologous strains would indicate a different serologic grouping between the organisms isolated from smallpox and the comparative strains. Complement fixation results run about parallel to the agglutination tests and are apparently no more specific. Streptococci isolated from smallpox produce a specific toxin which when injected into susceptible persons gives rise to a cutaneous reaction. The antitoxin produced in rabbits is specific as it neutralizes the toxin while normal serum has no effect.

Effect of High Fat Diets on Respiratory Metabolism and Ketosis of Man—Hawley and her associates studied the respiratory metabolism in seven subjects taking high fat diets. Following meals containing varying amounts of butter fat many respiratory quotients below the theoretical level for oxidation of fat were shown. The occurrence of these low quotients does not depend on the amount of fat taken in the experimental meal or on the fatty acid-to-dextrose ratio of the general diet, so much as on the tolerance of the subject. Adaptation to or tolerance of high fat in the sense of better capacity to oxidize fat and producing less ketosis may be acquired and retained for several months. The level of the respiratory quotient bears no intimate relationship to the demonstrable ketosis or ketonuria. Production of glycogen from the protein metabolism could account for a depression of the respiratory quotient at most of 0.025 while production of glycogen from glycerin, assuming that only the glycerin of the fat metabolism was available, would produce a depression of not more than 0.003. Correction of the quotient for the demonstrable ketosis and consequent ammonia formation would not account for more than 0.005. At most, the combined effect of all these factors would not account for quotients lower than 0.69. The formation of glycogen from fat (beyond the amount that could arise from glycerin) having never been proved, it would be premature to conclude that the quotients below 0.69 in this work demonstrate gluconeogenesis from fatty acids. The authors suggest, as an alternative explanation, that in the oxidation of fatty acid chains the uptake of oxygen may outrun considerably, for a time, the production of carbon dioxide and thus account for depression of the respiratory quotient. A process of desaturation that would remove hydrogen but not produce any carbon dioxide followed by oxidation with production of carbon dioxide, would fulfil the requirements.

Atropine Treatment of Postencephalitic Parkinsonian Syndrome—During the past year, Adams and Hays modified the dosage of atropine for the treatment of the postencephalitic parkinsonian syndrome. They used a 0.5 per cent solution of atropine sulphate beginning with 1 minim (0.06 cc) of the solution in a half glass of water three times a day, increasing the dose 1 minim a day until the fourth day, then 4 minims (0.25 cc) a day for three days, and then an increase of another minim a day until the tenth day, when 8 minims (0.5 cc) is

given for three days. On the thirteenth day the dose is continued at the rate of an increase of 1 minim a day until the optimal dose is established—this is usually between 12 and 18 minims (0.75 and 1.12 cc) given three times a day. Each case must be studied to determine the correct dosage—the quantity that just suffices to produce and to maintain physical and psychic euphoria. The authors found that this dosage overcame the toxic symptoms that occurred in some patients, such as nausea, vomiting, and paralysis of the bladder and the intestinal tract. The bladder became badly distended and had to be relieved by catheterization, but the distention of the abdomen could not be relieved by any treatment and it became necessary to discontinue atropine altogether, whereupon the symptoms would subside in about twenty-four hours.

Cancer Survey of Philippine Islands in 1929 C Reyes Manila—p 502
Percutaneous Treatment of Leprosy H Reitz Manila—p 511

Percutaneous Treatment of Leprosy—Reitz believes that to treat the entire skin simultaneously with a therapeutic substance can be accomplished only by percutaneous application, that is, by friction with the curative substance on the entire surface of the skin. On the assumption that it is possible to introduce therapeutic substances through the skin by friction, this method would be ideal for the treatment of leprosy, as it is far superior to the methods of subcutaneous and percutaneous injection. The author has worked out a new method of application, based on the fact that the skin is the principal and primary seat of leprosy, the bacteria of which are embedded either in the layer of the cutis or in the subcutaneous tissue. Only substances that are compatible with the cholesterol of the skin and are perfectly dissolved in the vehicle (which also must be compatible) have any chance to enter and pass through the epidermis and come to absorption. Therefore the passage of therapeutic substances through the skin depends on the character of the vehicle in relation to the skin and the character of the substance applied in relation to the skin and to the vehicle. Several patients who were suffering from advanced leprosy of the mixed type have been treated at San Lazaro Hospital with a substance of suitable character, worked out according to the individual requirements. The preparation was applied daily, by friction on the whole body, after the skin had been thoroughly cleansed with hot water and soap and dried carefully. The medicine was administered by the patient himself, who rubbed it into the entire front of his body by manual friction and the application to the back was made by another patient, the various patients thus helping one another mutually. The skin was left in this condition all day until the next morning, when the cleansing of the skin and the application of the medicine were repeated. No noxious effect to the health of the patient was observed during the entire period of treatment. The clinical lesions underwent radical change rapidly and the infiltrations, no matter of what character disappeared leaving behind a pale mark which gradually faded out. The skin, formerly disfigured by lesions and sometimes presenting a dreadful appearance, became clean and smooth. The patients now bear no visible signs of their former disease and the blood examination shows the negative character by the absence of bacilli.

Effect on Infant of Morphine Administered in Labor—Shute and Davis state that in morphine narcosis in the newborn the air passages should be cleared by means of a tracheal catheter if necessary, and external warmth should be applied. External stimulation is not only of doubtful value but often serves only to deepen the narcosis. Such stimuli may cause the baby to inspire once or twice and then to lapse into apnea, from which it is difficult to arouse. A mixture of carbon dioxide and oxygen gases proved to be the most useful stimulus to respiration. The authors regard the reaction of morphinized babies to these gases as a criterion of true narcosis. The administration of 30 per cent carbon dioxide with 70 per cent oxygen was the ideal mixture, especially effective when followed by pure oxygen. They present an account of all fetal deaths in their series, together with the pathologic observations in which necropsies were done. They feel that no baby in their group was lost as a result of morphine narcosis. Indeed, it has been their experience that morphine is a safe drug to use in labor, especially when adequate means of resuscitation are at hand. Many clinicians have relegated this drug to the background because of the possible development of the unpleasant complications of narcosis, only to make use of far more dangerous drugs of doubtful analgesic value.

Fractures in Lower Third of Both Bones of Forearm—In an analysis of 123 fractures Levinthal found that twenty-two (17.9 per cent) were fractures of both bones of the forearm, eighteen (14.6 per cent) of the total being in children. Fourteen of these fractures were in the lower third of the forearm. The four others were in the middle third. The authors' manipulative reduction of these fractures is carried out in a lighted fluoroscopic room, and it should be accomplished as soon as possible. The anesthetic of choice is ether. The fact that several days have elapsed since the accident should not deter the surgeon from attempting this maneuver. In an overriding fracture of both bones of the left forearm the surgeon stands at the left side of the table. The patient lies on the extreme right side of the table so that it is not necessary to move him when a fluoroscopic view is desired. The elbow of the patient is flexed at right angles, and an assistant encircles the arm of the patient with his hands. During the entire manipulation the forearm of the patient is held in complete pronation. The operator places his left thumb on the dorsum of the distal radial fragment and his fingers grasp the patient's hand over the thenar eminence. With his right hand he grasps the forearm over the distal end of the proximal radial fragment, the thumb of this hand resting on his own left thumb. Maintaining pressure with both thumbs on the distal fragment the operator gently angulates the fragments, increasing the deformity and at the same time exerting a distal push and some traction. The distal push by the thumbs is

maintained, the traction in the longitudinal axis is increased and the angulation is gradually decreased, as the fragments skid into apposition. The hand, wrist and distal fragments are straightened and gradually palmar flexed with moderate ulnar deviation, while the thumbs maintain their pressure on the distal fragments. The position of the fragments is checked by the fluoroscope. Should the manipulation fail, it should be tried a second and a third time if necessary. When the reduction is complete, a circular plaster cast is applied from the wrist to the palm, with the elbow at a right angle and the forearm in complete pronation. The cast is applied over a moderate amount of sheet wadding. Roentgenograms are taken as soon as the cast is dry. Finger motion is started early. The cast is bivalved at the end of from ten days to three weeks, the position of the fragments is verified by roentgenograms, and heat, passive exercises and light massage are started. In younger children, all retentive apparatus is removed at the end of from two to three weeks.

Postoperative Gastric Dilatation Treated with Insulin

—In the case reported by Mallory, a cholecystectomy was performed and no abnormality was found. The patient was discharged seventeen days later after an uncomplicated post-operative period. Eight days later he developed nausea and vomiting of all food and fluid. The only abnormality disclosed on physical examination was moderate distention of the abdomen with gas. Treatment consisted of gastric lavage, with the removal of a large amount of greenish liquid, a liquid diet, simple enema and rectal medication were given. The vomiting recurred and the patient was examined before the fluoroscope without a barium meal and the stomach was found to be filled within half an inch of the dome at the fundus. The stomach was again aspirated and 1,200 cc of fluid removed with fragments of prunes eaten six days previously. Further treatment consisted of physiologic solution of sodium chloride by hypodermoclysis repeatedly. On the fifth day feeding was resumed by mouth there was no further vomiting and the patient was discharged. He returned seven days later because vomiting recurred, 1,500 cc of greenish fluid was evacuated and a barium meal was given, he returned the next day and 1,200 cc of fluid was aspirated despite the fact that the patient had vomited five times during the night. The patient was readmitted to the hospital. The physical observations were the same as on previous examinations. Physiologic solution of sodium chloride 500 cc, with 5 per cent dextrose was given intravenously, with 10 units of insulin. Nothing whatever was given by mouth. The next day 200 cc of orange juice was given orally and 5 units of insulin was administered four times a day. The next day the diet was gradually increased by the addition of meat, bread and vegetables with 200 cc of orange juice between meals, and 5 units of insulin was given after each meal and after intermediate feeding of the orange juice. No further vomiting occurred. The patient was discharged on the seventh day and has been well for the past two months. The author believes that complete repeated evacuation of the stomach and the prevention of dehydration remain essential in the treatment of acute postoperative gastric dilatation. Insulin would seem to be a valuable physiologic remedy both in prevention and in treatment.

Chronic Hypertrophic Stenosis of Pylorus in Adults—

Chronic hypertrophic stenosis in adults is an uncommon benign cause of a prepyloric filling defect. The three cases described by Twining occurred in his private practice in a series of about 1,000 opaque meal examinations. Its interest for radiologists lies in the extreme difficulty of making a differential roentgen diagnosis from other stenosing prepyloric lesions, which it simulates so closely that in nearly all recorded cases a faulty preoperative roentgenologic diagnosis of carcinoma or prepyloric ulcer has been made. Minor degrees of pyloric hypertrophy are not uncommonly found at operation. Cases showing gross hypertrophy may require surgical treatment and it is important that a preoperative diagnosis should be made whenever possible. At present the roentgenologic criteria are by no means clear cut. The author presents a detailed study of his three personal cases in order to draw attention to the roentgenologic appearances and to stimulate a closer study of the condition.

 Heartburn in Pregnancy E. B. Ryner —p. 970

Duration of Passive Immunity to Diphtheria—Jones and Kershaw obtained passive immunity to diphtheria in a highly satisfactory proportion (97.9 per cent of all patients and 100 per cent of those under 10 years of age) of Schick positives by the injection of 500 units of diphtheria antitoxin. In adults and adolescents more than 15 years of age a larger dose is probably necessary. The duration of this immunity is at least fourteen days, and in the majority of cases (94.4 per cent) it extended to twenty-one days. The incidence of diphtheritic infection in passively immunized patients occurring at the times stated would suggest that it is unwise to regard this form of immunity as lasting longer than three weeks.

Carbon Tetrachlorethylene in Treatment of Hookworm Infection—Mapleston and Mukerji used carbon tetrachlorethylene in fifty cases of hookworm infection under hospital conditions and have cured thirty one with the first treatment and a further six with two treatments. The cure

rate after the second treatment would probably have been higher, but ten of the remaining thirteen persons left before it could be given to them, and thus there were only four patients out of the fifty who, the authors know definitely, were not cured by two treatments. Twenty one of the patients felt slight giddiness, nine vomited four felt nausea but did not vomit, and one said he felt drowsy for a short time. Of the nine who vomited, two did so immediately and the others at periods ranging between one and three hours after swallowing the dose. The dose was not repeated, so the vomiting probably had some effect on the total cure rate, and this supposition is supported by the fact that only two of the nine patients who vomited were cured by one treatment. The symptoms were never severe. There was no constant or significant change in the pulse and respiration rates, although there appeared to be a definite tendency for the blood pressure to fall in all the cases, but this was so slight as to be negligible in practically every instance. The authors observed no macroscopic evidence of damage to the small intestine either from single or from repeated doses of tetrachlorethylene. Their method of treatment consisted of placing 2 ounces of saturated magnesium sulphate solution in a 3 or 4 ounce flask or bottle and 4 cc of tetrachlorethylene and 1 cc of oil of chenopodium, the flask was corked and shaken until the drugs were distributed throughout the mixture in the finest possible droplets, and the dose was then given to the patient immediately before the drugs had time to coalesce into larger drops and float to the surface. Although the work of Garin and others indicates that tetrachlorethylene can be repeated with safety for two or three days in succession, the authors recommend giving it at intervals of no less than ten days, because it resembles other anthelmintics in causing the female hookworms to stop laying eggs for some days when it fails to remove them and so the establishment of a cure cannot be determined under that time.

Toxic Effects of Ephedrine—Chopra and Mukherjee point out that their studies indicate that toxic manifestations and undesirable side effects are commonly encountered after the use of ephedrine in asthma and other conditions. Some of the subjective symptoms are easily explained when one considers the physiologic action the alkaloid produces on the system. Ephedrine in doses of from 1 to 10 mg per kilogram of body weight is known to cause a rise in the blood pressure of anesthetized dogs by 100 or more millimeters of mercury and the rise is maintained at this level for at least fifteen to twenty five minutes. In human beings the rise in pressure is not so high as in animals but it varies from 20 to 65 mm of mercury. It is easy to see that circulatory reactions, such as palpitation and anginal pain, will be produced by the drug, particularly when the systolic pressure is at its highest level. The symptoms are also found to disappear as the pressure returns to normal. Insomnia and tremors are possibly due to stimulation of the central nervous system. Constipation, nausea and anorexia may be explained by the paralytic condition of the intestine due to sympathetic stimulation and loss of tone. Headache and throbbing sensations in the temples may be attributed to changes in pressure in the arterioles or veins within the skull. There is no agreement regarding the dosage required to produce these effects. Ephedrine is undoubtedly not a very toxic alkaloid and consequently there is a wide margin of safety. Its minimal lethal dose when given intravenously in dogs was found by Chen to be from 70 to 75 mg per kilogram of body weight. From this it can be inferred that a man weighing from 50 to 60 Kg would require from 4 to 5 Gm of the alkaloid to produce a fatal result. In contrast to this, the usual therapeutic dose is from one-half to 2 grams (0.03 to 0.13 Gm) and 7 grams (0.45 Gm) has been given in a single dose without untoward effects. The only explanation of the toxic effects appears to be a state of hypersensitiveness of certain persons to the drug. Ephedrine is a sympathomimetic drug and the stimulation of the sympathetic system in a highly strung individual may lead to symptoms of sympathoparasympathetic imbalance. It is also well known that slight differences in the amount of calcium in the blood make the autonomic system sensitive to sympathomimetic drugs of which ephedrine is one. If during its administration the patient exhibits toxic symptoms the drug should be discontinued.

Paravertebral Heterotopia of Bone Marrow in Jaundice—Hartfall and Stewart report a case of massive extramedullary hematopoiesis with intrathoracic localization of the tumor masses. There was little doubt that the patient suffered from familial acholuric jaundice. A sister died from the same disease and the examination of the blood of a brother now aged 52 showed that his red blood corpuscles possess undue fragility. Severe and recurring anemia existed in this patient for many years and it may be presumed that the heterotopic marrow developed excessively in this unusual situation in response to a demand for more red blood cells. That such a demand existed is shown by the hyperplastic character of the normal marrow. It is not clear why the localization of these accessory masses should be in this curious intrathoracic paravertebral site, but the same distribution was present in the cases reported by Dawson, Rich, Plonskier and Saleeby, as well as in Hunter's two unreported cases. Saleeby's patient was the only one that was not anemic. Examination of the nodules showed that they were not extensions from the marrow of adjacent ribs or vertebrae, for no pedicle or other communication could be found. The masses were in fact completely circumscribed. It has been suggested that these formations develop from small bone marrow heterotopias of embryonic origin, are examples of post-fetal metaplasia or are true benign tumors. The heterotopic view is supported by the fact that the commonest situations in which small foci develop are the liver, spleen, kidneys and suprarenals sites in which embryonic hematopoiesis normally occurs, while even the larger nodules have been most frequently reported in connection with the kidney. In these organs it is conceivable that the embryonic hematopoietic tissue might survive into the postfetal period and, under the influence of a suitable and prolonged stimulus, undergo an adaptive hyperplasia. If chronic anemia serves indirectly as the stimulus the wonder is that such ectopic nodules are not found more frequently. It is possible that a careful search in appropriate cases might reveal the frequent presence of nodules of marrow tissue within the thorax in the paravertebral angle, but the reason for this special localization would still remain obscure.

Intracranial Tuberculoma—From an analysis of 13,000 consecutive necropsies Garland and Armitage found that the incidence of intracranial masses is more than 2 per cent of all cases coming to necropsy, and of these more than half are neoplastic. Tuberculomas constitute 34 per cent of all intracranial masses, 63 per cent of all masses in patients under the age of 20 and 66 per cent in children. Above the age of 20, 17 per cent are tuberculomas. Tuberculoma is slightly more frequent in women. There is no evidence of a diminishing incidence in the twenty-one years under the authors' review. In half the cases the tuberculoma is solitary. The cerebellum is involved in 67 per cent of cases and the cerebrum in 47 per cent, the commonest type of lesion being the solitary cerebellar mass. Death results from tuberculous meningitis in 75 per cent of cases and from some other tuberculous lesion in 20

per cent. Death from increased intracranial pressure is rare. Calcification and healing are rare and, unlike gumma, tuberculous masses are rarely adherent to the dura mater. Tuberculomas rarely give rise to symptoms prior to the onset of tuberculous meningitis. There are no characteristic clinical manifestations of intracranial tuberculoma but pyrexia occurs at some stage in 90 per cent of cases. The discrepancy between the pathologic and surgical incidence of tuberculoma can be explained only by the absence of clinical manifestations prior to the onset of tuberculous meningitis.

Histology of Neuroparalytic Accidents—Getzow and his associates discuss the histopathology of three cases of acute ascending paralysis of the Landry type, two were definitely connected with the administration of antiribic treatment and the third and most rapidly fatal developed without apparent cause. The microscopic appearances in the central nervous system are similar in the three cases and differ markedly from those detailed in previous reports of posttreatment paralysis. The authors endeavored to determine the microscopic appearances in the neuroparalytic accidents of antiribic treatment. They found that the paralysis is due to disturbance of the ganglion cells, motor and sensory alike, characterized by primary nuclear changes proceeding often to complete karyolysis and final cytolysis. Microscopic examination of the brain and spinal cord revealed little more than varying degrees of a degenerative change in the nerve cells. Between the normal ganglion cell nucleus and its antemortem stage there have been encountered certain intermediate types that permit affected nuclei to be divided into three categories: the clear basophilic type, the dark basophilic type and the dark basophilic homogeneous type. The positive histologic observations additional to the fundamental ganglion cell changes included marked edema of the gray substance in the cord, most pronounced in the lumbosacral portion, enlargement of the perivascular and pericellular lymph spaces, engorgement of the small vessels and edema of the glia. There were no focal lesions, no destruction of nervous tissue (apart from the ganglion cells), no demyelination, no change in the axis cylinders, no focal increase of neuroglia, no perivascular or pericellular aggregations and no fat in the three cases. The authors believe that such rapid involvement of the cerebrospinal axis with nervous tissue destruction, diffuse indeed but strictly limited to ganglion cells, indicates the highly selective action of some toxin on these cellular elements of the central nervous system. The extreme activity of this toxin is best illustrated by the occasional speedy dissolution of water-clear almost normal nuclei, while the occurrence, even if rare, of perfectly intact bodies of cells without nucleus or with a nucleus in an advanced state of degeneration presupposes the existence of karyolytins and suggests their incrimination in a primary attack launched on the ganglion cell nuclei.

Clinical Applications of Dimitro-Orthocresol—The results of the studies of Dodds and Robertson with dimitro-orthocresol indicate the extremely powerful action of bodies of this group and consequently the extreme caution with which their administration must be attended. A safe dose that will cause a definite increase in the basal metabolic rate would

appear to be between 50 and 100 mg. daily for a normal person or from 0.5 to 1 mg. per kilogram of body weight. Under no circumstances should the compound be administered in such quantities as to raise the basal metabolic rate above +50, as otherwise grave discomfort and danger will result. It must also be borne in mind that neither the pulse rate nor the blood pressure is of any value in assessing the basal metabolic rate, since the characteristic action of this compound is an increase in metabolism without a proportionate stimulation of the cardiovascular system such as occurs with the administration of thyroxine. Any attempt to arrive at the basal metabolic rate by the use of Read's formula would give misleading results. It would appear, therefore, that the action of the drug should always be checked by determination of the basal metabolic rate. These experiments show that it is possible to maintain the metabolic rate at a figure from 30 to 50 per cent above normal without the appearance of any discomfort or toxic symptoms. It follows that provided the diet is not grossly in excess of the person's requirements weight will be lost, and it is possible to adjust the intake so that a steady loss of weight results. This will be possible without undue privation. A series of such cases is at present under examination. It would appear that dimitro-orthocresol is about five times as potent as the dinitrophenol compound, as judged by clinical observations.

Acholuric Jaundice with Increased Fragility of Erythrocytes After Splenectomy—Thomson points out that cases of acholuric jaundice may present great difficulties in diagnosis as jaundice may be inconspicuous or even absent and the only principal feature may be unexplained anemia. In most cases there is evidence of increased fragility of the red blood corpuscles which gives a clue to the diagnosis, it is well known however that this fragility may vary in degree not only in different patients but also at different times in the same patient. In the author's patient there was no evidence of increased fragility in the two examinations carried out before the operation and the second of these was done only a fortnight before the onset of acute illness. Reticulocytosis of considerable degree is an important feature of many cases of acholuric jaundice, but in the case recorded it was found only once. It was slight in amount (3.4 per cent) and had disappeared a week later. Splenectomy was decided on on this admittedly slender evidence. The effect of splenectomy on fragility is variable, according to Dawson it remains unchanged in half the cases and is reduced in the remainder. In his paper he mentions one case in which it had been found that the fragility increased after operation. So far as the author is aware the history of his patient is the only one of this type to have been put on record. It is difficult to suggest a completely satisfactory explanation of the unusual course of the case, provisionally he accepts the simplest as the most likely to be true. It seems to him that it is possible that, when hemolysis in the spleen is active, all fragile corpuscles may be removed as soon as they enter the blood stream from the bone marrow and that consequently the estimated fragility of the blood removed from a vein may remain normal. After splenectomy, fragile corpuscles may circulate in the blood stream as they will not be removed by the spleen, and the general fragility of the red blood corpuscles in the peripheral circulation will therefore be increased. Should this be the true explanation, the author states that he would have expected the anemia to be more profound in his patient and he can only assume that the proportion of fragile corpuscles produced was not great.

Pellagra—Of the twenty-six cases of pellagra that Biggam and Ghalioungui observed during the last twelve months all presented the typical rash, twenty-four a glazed tongue, twenty-

one nervous or mental manifestations (this includes cases showing only increased reflexes) and fifteen only cutaneous and nervous symptoms, while in six digestive symptoms were also present, in two digestive disturbances and, in three, only cutaneous manifestations. No special treatment is necessary for the cure of the cutaneous and digestive manifestations. The ordinary hospital diet, after getting rid of any parasitic infestation, is sufficient to cure them, and the rash usually disappears within two to four weeks after treatment is commenced. This does not always bring about a cure of the nervous or mental manifestations. Once the latter have appeared in a well defined form, improvement is extremely difficult to obtain, but simple dulness or a feeling of depression easily disappears under this treatment. Recently, Sargent states that he has obtained recovery in cases of subacute combined degeneration of the cord associated with anemia, Addisonian or otherwise, by the administration of 150 grains (9.75 Gm) of ferrous carbonate in the form of pills daily for six weeks. More recently he described one case treated on these lines with benefit, in which there was no associated anemia. Owing to the similarity between the pathologic changes of the nervous lesions of the anemias described and that of the lesions accompanying pellagra, the authors tried this form of treatment in six of their cases, and their results agree closely with the results obtained in Sargent's cases, i. e., considerable improvement in the functional state of the nervous system with little corresponding changes in the nervous signs.

An "Acid-Fast" Other Than Koch's Bacillus—Cummins and Williams describe an organism found under circumstances that would almost certainly have led to an erroneous diagnosis had the investigation stopped short of cultural tests and animal inoculation. The patient was a woman suffering from acute pulmonary disease, which had come on shortly after confinement. The picture was that of acute phthisis, but the sputum had been reported negative on several occasions. The authors found in a sample of sputum numerous acid-fast bacilli scarcely distinguishable from tubercle bacilli but showing a few curious balls of curved rods which were sufficiently peculiar to raise the question of an unusual morphologic type. From a culture a growth was obtained and from another sample of the sputum sent to Griffith six weeks later the same organism was cultivated. Whether the germ was merely an adventitious saprophyte or the causative organism of the severe pulmonary disease from which she suffered must remain open to question as opportunities for further biologic tests were refused. The authors emphasize the fact that the finding of acid fast bacilli in the sputum is not necessarily positive proof of tuberculosis. The importance of cultural verification in all doubtful cases cannot be stressed too much.

Observations on an Acid-Fast Bacillus—In the specimen of sputum from the patient having acute pulmonary disease sent to Griffith by Cummins an acid fast bacillus was obtained in culture directly from the sputum after treatment with 25 per cent potassium hydroxide. After an incubation of five days at 30 C one colony was seen on a glycerin egg and one

on an egg tube, on the latter tube another colony was seen on the eighth day and this colony was then the size of a pinhead grayish white and hemispherical. The colony on the glycerin egg tube grew much larger than that on egg and finally was heaped up, cream colored and convoluted, surrounding it for a wide distance there was a thin almost invisible marginal growth with fernlike markings, beneath which the medium acquired a dark color on exposure to light but the growth itself remained unchanged. The colonies on the egg medium were light buff, prominent and conical the larger about 3 mm in diameter, the surfaces, mainly toward the apexes, became studded with rounded prominences, the colonies had very narrow thin margins and the medium beneath was not darkened on exposure to light, but some of the prominences became slaty gray. In subculture the strain grew fairly rapidly and abundantly, producing moist easily spread and emulsified growths, which were whitish on the egg mediums and slightly creamy on glycerin agar and potato and bovine serum. A pellicle was produced on broth and the growth tended to break up and sink forming a deposit. The micro organism is strongly acid fast and alcohol fast and grows at temperatures ranging from 15 to 37 C. It retains its vitality in culture for long periods. The strain did not absorb the agglutinin from an avian antiserum (rabbit). The author found that this strain of acid-fast bacilli is pathogenic for rabbits and mice when introduced in relatively large doses intravenously or intraperitoneally but that it has little pathogenicity for the guinea-pig and none for the fowl or the frog. The strain differs from tubercle bacilli both in cultural characters and in its effects on animals and is not identical with any of the acid-fast strains of bacilli which he has obtained from tubercle-like lesions in cold-blooded animals or any of the saprophytic acid-fast bacteria with which he has worked.

Cobra Venin in Treatment of Algeries and Tumors

The favorable action of cobra venin on the hyperesthesias caused by tumors that cannot be operated on is becoming more definitely established. The cachexias frequently associated are also often improved. Orticoni notes that anesthesia occurs with relative rapidity when the venin is injected near the site of the tumor. He feels that it probably acts directly on the nerve fibers. The improvement in the cachexias so frequently observed may be due to a tonic action of the venin but the author thinks that the change is so rapid and lasting that the venin more probably inhibits directly the destruction of the malignant cells. Although cobra venin so far has been used exclusively in the algeries produced by malignant growth, the author quotes Calmette as suggesting that there is a fertile field for investigation of its effects in hyperesthesias and neuralgias of other origins.

Relation Between Calcium and Phosphorus in Blood Plasma—Meli and Cammarella found that varying daily intravenous doses of sodium oxalate in rats and rabbits produce a diminution of the plasma calcium and a proportionate rise in the values of organic phosphorus. Injections of calcium produce not only a temporary rise in the calcemia but a simultaneous and proportionate diminution of the phosphatemia. Treatment with a neutral phosphate results in a rise of the phosphatemia and slight diminution of the calcemia. Sodium citrate scarcely affects the calcium content but occasions notable increases in phosphatemia while the blood becomes noncoagu-

lable. These alterations of the mineral composition of the plasma may be observed after prolonged treatment and also a few minutes after a single intravenous injection. A mixture of calcium chloride and sodium citrate in corresponding amounts is more effective than ionizable calcium salts in raising the degree of calcemia, whereas it does not alter the degree of phosphatemia. The literature shows without exception an identical synchronism in the deviation from normal of the plasmatic values of calcium and phosphorus, the two being displaced proportionately. The relation does not exist between the phosphorus and calcium in the blood but rather between the ionized parts of these two elements and, grossly, between the dialyzable fraction of calcium and the inorganic fraction of phosphorus. This fact explains why the plasmatic chemical picture of osteomalacia and rickets may be experimentally reproduced with sufficient exactness by treatment with citrate and with citrate and calcium. The relation between the plasmatic values of calcium and phosphorus remains constant. Thus it is impossible to determine in individual cases whether the primary change is imputable to the calcium metabolism or to the phosphorus metabolism.

Technic of Subserous Appendectomy.—Iriarte and Olivera say that the subserous technic in appendectomy is a simple and rapid procedure, which is applicable to all cases. By this technic there is no danger of immediate or secondary hemorrhage. It is the only procedure that should be followed in cases of appendices covered with membranes and surrounded with friable tissues which make the dissection of the appendix a dangerous operation and make peritonization of the appendicular stump impracticable. The authors describe the technic by means of illustrations. In 1126 appendectomies they have not observed any complications for which the method might be blamed. With an early diagnosis and the opportune surgical intervention by the subserous technic used systematically, there should be no mortality in appendectomy.

Acute Erosive Gastritis.—Hanke administered caffeine to cats in subcutaneous doses of from 1 to 3 Gm. in his animal experiments on the production of acute erosive gastritis. This was followed by the development of definite macroscopic and microscopic alterations in the gastric mucosa in the form of localized erosions. These lesions occurred with greatest frequency in the body of the stomach but were likewise seen in the pyloric portion, while with the aid of microscopic studies, defects in the duodenal mucosa were demonstrated. The erosions resembled those produced by morphine or pilocarpine in that they were limited to the superficial layer of the mucosa and

showed a tendency to spread into the depth. An individual lesion frequently presented a fibrinous necrotic layer with beginning leukocytic infiltration and perifocal edema. The absence of diffuse gastritis suggests that these erosions were not primarily the result of toxic action. The histologic picture likewise did not suggest the existence of spasmogenic factors, such as muscular or arterial spasms. There was nothing in this histologic picture to suggest an infarct nor did the limits of erosions correspond to those of blood vessels. The author therefore concluded that the erosions were of a peptic character, the result of acid gastric secretion. Caffeine in large doses has the effect of provoking a copious secretion of acid gastric juice. This view was supported by the study of the gastric secretion of the cats in the experiment. Focal localization of lesions is conditioned by the fold system of the gastric mucosa. The results of these experiments lend support to the theory of Buchner that gastric juice alone is capable of producing peptic lesions.

Treatment of Hemorrhoids.—Peters believes that the greater incidence of hemorrhoids in men than in women (four to one) is due to the differences in the pelvic floor and in the caliber of the pelvic veins. The pelvic floor in man is narrower and is composed more of connective tissue than of muscle. Its anterior portion is occupied by the muscular prostate gland, so that the entire intra-abdominal pressure is exerted against its only yielding portion, the anal region. In women the pelvic outlet is considerably wider, is more muscular, and contains in its anterior portion a sort of regulating valve with the vagina acting as the point of lesser resistance. The veins in women have a wider lumen. Attention is called to the fact that the most frequent cause of hemorrhoidal nodes is cardiac insufficiency. Intermittent chronic or acute and that operation is contra-indicated in these cases. Hemorrhoids do not call for any treatment except hygiene of the anal region, until pain is complained of or symptoms of inflammation set in. These are met by conservative measures such as sitz baths and the use of astringent solutions or salves. Surgical treatment is not indicated as long as there is no gangrene, periproctitis or thrombophlebitis. Generally speaking conservative treatment is indicated for hemorrhoidal nodes resulting from acute dilatation or insufficiency of the hemorrhoidal veins, while surgical removal is necessary in the case of genuine varicosities or angiomas. The author discusses methods of cautery operation, excision and injection. The objections to the excision method of Whitehead are the incidence of from 37 to 74 per cent (Stone) of recurrences, incontinence, strictures and persistent discharge of mucus leading to pruritus and eczema. The operation is rather difficult and the average hospitalization is from twenty to twenty-six days. Among 649 patients operated on by the cautery method in the author's clinic, there were 518 men and 131 women. The duration of hospitalization was 11.79 days for men and 13.54 for women. A follow-up study of 177 cases showed that 94.92 per cent were permanently cured, 2.28 per cent were improved and 2.26 per cent presented recurrences but were cured by reoperation. There was no instance of stenosis. The author concludes that the oldest method, that of cautery operation, originated by Langenbeck, is the best method. Its advantages are simplicity, a sterile field, applicability of local anesthesia, short hospitalization, retention of sphincter function and excellent results.

Massive Intravenous Infusions.—Warthen studied the effect of intravenous administration of various solutions on the blood chemistry in animal experiments. He introduced into

the femoral vein of a dog up to 2 liters and more of the solution in a relatively short time. The quantities administered amounted to from 56.6 to 210.5 cc per kilogram of the body weight. The rest nitrogen of the blood serum diminished after the administration of a 5 per cent solution of dextrose by 13.6 mg per hundred cubic centimeters, while after the administration of a hypertonic salt solution (from 1.5 to 2 per cent) it increased by 0.8 mg. The blood sugar content increased by 0.1 mg after the administration of the physiologic solution of sodium chloride, but diminished by 20 mg after administration of the hypertonic salt solution. The blood chlorides rose 100.4 mg per hundred cubic centimeters after the infusion of physiologic solution of sodium chloride and only slightly more after the hypertonic salt solution. This rather surprising effect is explained by the fact that the hypertonic solution in these experiments was injected into normal animals. The blood chlorides diminished after the administration of a 5 per cent solution of dextrose by 13.9 mg per hundred cubic centimeters, and by 59.3 mg after the injection of a 10 per cent solution of dextrose. The resistance of the red corpuscles showed only slight diminution after the physiologic solution of sodium chloride and no change after the hypertonic salt solution. There was only one fatality in the twenty-eight experiments. This animal died after an infusion of an exceedingly large quantity of a 10 per cent solution of dextrose. A postmortem showed no transudation into the pleural cavity, the pericardium or the peritoneal cavity. Death apparently was due not to circulatory disturbance but to an excessive amount of dextrose. The author concludes that the enormous quantities introduced did not cause circulatory disturbances. Corresponding quantities for human beings would amount to 7 or 8 liters for an adult weighing 65 Kg, which is several times that ordinarily used in clinical work.

Therapy of Infectious Diseases with Synthetic Medicines—Schulemann discusses chemotherapy. He evaluates the chemical preparations used in the treatment of nematodes but admits that they have added little to the formerly employed anthelmintics provided by nature. Chemotherapy was much more successful in the treatment of diseases caused by protozoa such as malaria, trypanosomiasis, leishmaniasis, frambesia and amebic dysentery. In diseases of bacterial origin, particularly the spirochetoses, syphilis and recurrent fever, chemotherapy proved effective, and it was resorted to with some success in tuberculosis, leprosy and diseases of pneumococcal, staphylococcal and streptococcal origin. In diseases caused by ultra-violet viruses chemotherapy has failed. The author points out that mere accident has never produced results in chemotherapy but that the studies were always guided at least by a hypothesis, and for further studies he emphasizes the necessity of close cooperation between the chemist and the physician.

Hormonic Regulation of Female Cycle—Schoeller shows that the normal course of the female sex cycle is dependent on the harmonizing collaboration of uterus, ovary, hypophysis and midbrain which is effected by hormonal influences. In discussing the gonadotropic hormone of the anterior hypophysis, he points out that under its influence two ovarian hormones are formed the follicle hormone and the hormone of the corpus luteum. This has led Zondek and Aschheim to assume that the gonadotropic hormone of the anterior hypophysis consists of two factors which they designate as prolan A and B and which they think are produced successively in the hypophysis, as indicated in the succession of the maturation of the follicle

and the formation of the corpus luteum. Although efforts have been exerted to separate prolan A and B it has not been accomplished as yet, and Evans does not believe in the existence of the two factors. The author calls attention to Philipp's observation that during pregnancy the anterior hypophysis is practically free from gonadotropic hormone. This apparently contradictory observation becomes understandable in view of the retroaction of the gonadic hormones on the hypophysis. This retroaction is accomplished indirectly by way of the central nervous system. In the hypothalamic region of the midbrain there must exist a center, which, in the event of a reduction of the gonadal hormones, stimulates the hypophysis by nervous impulses. Thus it is not the hypophysis as such that regulates the ovary but rather the sex center. Moreover, on the basis of studies on patients with cystic hyperplasia of the uterine mucosa, it appears that luteinization is effected by the ovary rather than by the hypophysis, and the author reasons that if this is the case a separation of the gonadotropic hypophyseal hormone into prolan A and B is no longer necessary and the hormone may be considered a unit.

Changes in Sympathetic Nervous System in Gastric Ulcer—Stohr relates his observations on the nervous apparatus of forty-four stomachs that had been resected on account of ulcer. He shows that the nervous tissue in the center and in the immediate surroundings of the gastric ulcer presents an almost inexhaustible multiplicity of formations and points out that attempts have been made to produce a gastric ulcer experimentally by interventions on the vagus and the sympathetic. He considers it impossible that resection of nerves produces such complicated changes in the intramural nervous system as exist in chronic ulcer. In case of a disease condition of the gastric nerves, purely anatomic factors necessitate the consideration of the entire sympathetic nervous system but from the same anatomic point of view it appears hardly possible that abnormal vascular conditions, secretory disturbances, muscular spasms or inflammatory manifestations can alone be the cause of gastric ulcer, for without the sympathetic nervous system not a single cell is able to function.

Acetarsone in Congenital Syphilis—Eckardt employed oral acetarsone treatment in small children having congenital syphilis, some of whom had previously been subjected to other antisyphilitic injection treatments, while others had received no other treatment. It was found that treatment in which from 12 to 15 Gm of acetarsone was administered in the course of about twelve weeks was generally adequate. As a rule, periods of four, six and later ten days of medication with acetarsone were followed by pauses of four days. According to the weight and condition of the child, the treatment is begun with from one eighth to one fourth of a 0.25 Gm tablet daily. This dose is later increased to one half tablet and in the further course of the treatment the half tablet is given first twice and later three times a day. After twelve weeks of this procedure the treatment may be stopped, but if necessary it is repeated after an interval of four weeks. The efficacy of the treatment becomes manifest in a surprising improvement of the general condition. The children usually thrive and gain in weight. The exanthem

and the rhagades gradually disappear. Even disturbances of the bones, such as syphilitic periostitis and Parrot's pseudo-paralysis, are favorably influenced. The coryza often persists for longer periods and in the severe forms of visceral syphilis acetarsone is generally no more effective than other antisyphilitic remedies. The reduced blood pressure frequently increases in the course of the treatment. As a rule, the Wassermann reaction becomes negative during the second half or at the end of the treatment and only occasionally remains positive for some time after the first cure. The author concludes that the high percentage of effectiveness of acetarsone and the simple oral application make it the method of choice in the treatment of congenital syphilis.

The Central Nervous System in Pneumonia—This is one of a series of investigations on the role of the hemato-encephalic barrier in nutritional intoxication in infants. In this one Schaferstein and his associates describe their histologic observations on eight children, who died of pneumonia. They show that during early childhood nutritional disturbances leading to decomposition but without the toxic syndrome are accompanied by numerous changes in the central nervous system. In the soft meninges there exist mild inflammatory processes, and the nerve cells of the cerebellum and of the tuber cinereum show degenerative changes, which must be considered the result of the intoxication of the nervous system. In children the elements of the hemato-encephalic barrier are highly susceptible to various injurious agents. However, mild inflammations of the pia mater may pass off without clinical symptoms. The cerebral aspects of the toxic and decomposing nutritional disturbances differ from those in pneumonia, particularly in regard to the most frequent points of attack.

- Obstetric Diagnosis of Thoracopagus W. Haupt—p. 148

Acridine Dye in Treatment of Gonorrhea in Women—Kittner employs a derivative of acridine which contains arsenic. The substance is generally used as a 2 per cent solution of reddish yellow coloration but it can be applied also in the form of swelling suppositories. The author employed the substance in fifty-one cases. He treated gonorrhea of the neck of the uterus by means of a syringe constructed in such a manner that every revolution of the plunger ejects only 1 cc. of the substance. The tube introduced into the uterine neck contains several openings and the fluid does not emerge as one stream but comes out of several openings, so that the mucous membrane is well irrigated. The quantity of fluid introduced varies according to the size of the uterus and the width of the cervical canal. Since the substance may exert a corrosive action on the vaginal mucous membrane fluid that may flow back into the vagina should be removed and a dry cotton tampon should be placed in front of the uterine opening. The author observed a peritoneal shock action in only one patient, and the symptoms disappeared again in a comparatively short time. In another patient an urticarial exanthem developed, but it disappeared again within twenty-four hours. In urethral gonorrhea irrigation with the solution of the acridine-arsenic preparation is done twice daily and is followed by the introduction of a swelling suppository. Mild forms of cystitic irritations were noted frequently, but they were not severe enough to necessitate interruption of the treatment. For rectal treatment the author recommends the daily (morning) injection of 3 cc. of a 0.25 per cent solution of the preparation into the rectum and the introduction of a suppository. In summarizing his observation on the fifty-one patients, he states that the preparation effected cure in 77 per cent of the women with cervical gonorrhea, the treatment lasting twenty days at the most. In some of the patients, other treatments had proved ineffective.

Removal of Foreign Bodies from Urinary Bladder—According to d. Erchia the direct, that is, the urethral, route is the best for the extraction of foreign bodies from the urinary bladder. This method is often possible if removal is attempted shortly after the foreign body has been introduced and before it has caused inflammatory processes. However, if the removal has been delayed, the foreign body may have become encrusted with deposits of calcium salts, or cystitis, pyelonephritis and perivesical phlegmons may have developed. Such complications are especially likely if the points of the foreign body, for instance of a harpin, have perforated the mucous membrane and have entered the perivesical tissue. In cases of this type, and also when foreign bodies have been forgotten in the course of a laparotomy and have caused abnormal connections between the bladder and the neighboring organs, the author recommends colpocystotomy, in spite of the fact that some have advised against it on the ground that it leads to undesirable complications, such as fistulas. The author performed the operation successfully in three cases. He opens the bladder in the anterior third through the anterior vaginal wall. Following extraction of the foreign body, the walls of the bladder and vagina are sutured separately and a permanent catheter is introduced. In the first case a urinary fistula developed following removal of the catheter but its repair was not difficult. In the other two cases healing by primary intention was accomplished because the vagina and the bladder were separated more extensively and were sutured separately. The foreign bodies removed by the author were harpins in two cases and a thermometer in one case. The removal of the harpins had first been tried by the urethral route and had been unsuccessful, but in the case of the thermometer this method had not been tried in order to avoid breaking of the instrument.

- Early Diagnosis of Bronchus Carcinoma H. Kahler—p. 86

Clinical Significance of Agalactosuria—Singer and Wechsler point out that a galactose tolerance test was recommended by Bruer as a functional test of the liver. Elimination of more than 3 Gm. of sugar in the urine, when 40 Gm. was taken, is considered indicative of a diffuse impairment of the hepatic parenchyma. Donath called attention to the fact that complete absence of galactose, agalactosuria likewise has pathognomonic significance and the authors investigated the pathogenesis and the significance of this symptom. By determining the galactose content of the blood, they determined that agalactosuria may develop in two different ways. 1. No galactose goes from the portal circulation into the general circulation and thus there can be no agalactosuria in the absence of galactosemia. This form of agalactosuria develops particularly in achylia refractory to histamine and concurring with severe anemias either pernicious anemia or achylic chloranemia, but it also develops in achylia without anemia and in duodenal stenoses with or without achylia or anemia. The authors think that in these forms there exists a disturbance in the resorption of the galactose and consequently they suggest the term 'enterogenic' agalactosuria. 2. Severe galactosemia exists, but the renal threshold for sugar has been heightened to such an extent that no galactose passes into the urine. This form is observed in serious renal diseases and is designated as 'nephrogenic' agalactosuria. The authors conclude that agalactosuria so far has not been given sufficient attention. Its presence indicates renal or gastro intestinal disturbances and calls for further investigations to determine their exact nature.

- Erythema Nodosum Tuberculous Character W Gobel and E Schuhardt—p 260
- Comparative Morphology of Tuberculosis According to Age Periods V Pusik—p 266
- Vioosterol and Tuberculosis A de Carvalho—p 271

Erythema Nodosum and Tuberculosis—Gobel and Schuhardt try to demonstrate that erythema nodosum is closely related to tuberculosis. Investigators who reject such a relationship call attention to the fact that erythema nodosum is extremely rare compared to the high incidence of tuberculosis. To this the authors reply that erythema nodosum is not the exanthem of tuberculosis alone but that other factors besides the tuberculous infection are necessary for its development. The tuberculosis may be a new infection, either a primary one or a superinfection, but it may also be an old process that apparently had taken its course. The factor that favors the development of erythema nodosum may be (1) a constitutional weakness of defense (2) an endogenous disturbance in the defense mechanism (hormonic cycle seasonal increase in the reactivity) and (3) an exogenous disturbance in the defense powers (infectious diseases, or application of tuberculin). The authors report a case in which they explain the development as follows. As indicated by the demonstration of tubercle bacilli and the severe reaction to application of tuberculin at the time of the boy's admittance to the institute he had been infected previously. He also had a lamblasis which produced a negative energy. When he was put with other tuberculous patients he developed a new infection which, because it took place at the time of a negative energy led to erythema nodosum and also produced a tuberculous infiltrate with the typical roentgenologic and clinical aspects.

Vioosterol and Tuberculosis—According to de Carvalho the therapeutic effects of vioosterol in tuberculosis are still being disputed. The clinical as well as the experimental results of investigators differ considerably. The action of vitamin D becomes manifest not only in calcium fixation but particularly in the general condition through an increase in appetite and weight. The author treated twelve guinea-pigs for thirty-two days with vioosterol and then infected them with tubercle bacilli. He infected twelve and then treated them with vioosterol and he infected twelve more but did not treat them with vioosterol. Of the ten surviving animals of the first group, all but one showed an increase in weight after the infection, half of the second group of animals increased in weight in spite of the infection, and of the third group only three animals showed an increase in weight. The necropsies revealed that the infection was most severe in the third group, and mildest in the second group. The animals of the first group did not show a favorable influence from the prophylactic vioosterol treatments as some of their organs presented even more severe infections than did those of the animals of the third group.

- Shaped Incision for Opening of Uterus in Cesarean Operation L Drüner—p 131

Treatment of Placenta Praevia—Gauss in a tabular report of more than 10,000 cases shows the mortality rates of the various methods of treatment for mothers and infants. This report indicates that spontaneous delivery with or without rupture of the bag of waters should be the first aim as it involves the lowest mortality. If bleeding persists after the rupture of the bag of waters other methods become necessary. Vaginal

tamponade is inadvisable because of its extraordinarily high maternal death rate. The use of the metreurynter and of indirect version offers a considerably smaller maternal mortality but the death rate of the infants is extremely high, particularly in the case of indirect version. Vaginal and abdominal cesarean operations have a considerably smaller infantile mortality and the maternal death rate is slightly less than in case of metreurynter but the author is not in favor of these methods. In dispensing largely with vaginal tamponade, the use of the metreurynter and cesarean section he has not been obliged to resort more often to indirect version and in the last few years he has employed it only about half as often as formerly. In 60 per cent of cases of placenta praevia he has resorted to what he terms the "scalp forceps." This method greatly reduced the necessity of surgical interventions. Following the rupture of the bag of waters the child's head is brought down and pressed against the bleeding site of placental attachment. The author accomplishes this by grasping the exposed portion of the child's scalp with a suitable forceps and attaching to this scalp forceps a traction device with a weight of from 500 to 1,000 Gm. The result is that hemorrhage ceases, the uterine contractions become stronger the mouth of the uterus gradually dilates and a spontaneous delivery in cranial position takes place. There was not a single maternal fatality in the cases in which the method was employed. The infantile death rate was rather high, but not as large as in indirect version.

The Impaired Heart Following Irradiation of Ovaries—Pohl demonstrates that, in patients having heart disease irradiation of the ovaries is likely to cause further impairment of the heart action. This is the case particularly if insufficiency existed shortly before or is still present. It is probable that the cardiac impairment is the result of the sudden decrease in blood pressure caused by the irradiation. The decrease is most noticeable in hypertension, and this explains why the manifestations of decompensation produced by irradiation of the ovaries is most severe in patients having high blood pressure. The author concludes from these observations that, in case of cardiac decompensation, the irradiation should always be preceded by treatment with strophanthin. Moreover, even in compensated cardiac defects the heart action should be watched during irradiation.

Incision in Uterus in Cesarean Operation—Drüner calls attention to the advantages of the Y-shaped incision employed by him. The lower branch of this incision is in the cervical portion of the uterus, the two upper ones reach into the musculature of the fundus, and they take into account the course of the fibers of the smooth muscle even more than does the curved incision. The fact that by the lower branch of the incision the circular muscle fibers are divided vertically is apparently a disadvantage, but the author asserts that he never noticed that it had undesirable results. For the opening of the peritoneum he employs a curved incision parallel to the vesical fold. Thus the incisions are not over each other but only cross each other in the center. The author had the opportunity to observe several of the scars in the course of second and even third cesarean operations. He never observed defective scars and, even in subsequent normal deliveries the scars did not cause complications. Hernia developed in one instance because of prolonged suppuration of the abdominal walls.

Calcium Gout—Elenevskiy and his collaborators state that, compared with uric acid gout, calcium gout is rare. According to Umber, six cases were observed in Germany between 1910

and 1921, while Profichet reported eight cases in France. Calcium gout occurs principally in young women. It appears to be the result of disturbance of the calcium metabolism associated with dysfunction of the parathyroid apparatus. The disturbance of albumin metabolism in the absence of clinical manifestations of hyperthyroidism, in the case of the authors suggests a possible role of the parathyroids in the metabolism of albumin. Alterations appeared principally in the subcutaneous reticulum and the periarticular tissues of the fingers and toes in the form of tophi. When removed the tophi were found to contain copious deposits of a white chalklike substance. Chemical analysis showed the presence of traces of uric acid salts of phosphates, of large amounts of calcium salts and of carbonates. The dynamic method of determination of the purine and the calcium metabolism permits of a differentiation between the two. The differential diagnosis between uric acid gout and calcium gout is further made possible through roentgenologic study. The roentgenogram of the latter presents a characteristic appearance of circular shadows about the phalanges arising not in the joints but in the soft periarticular tissues. Histologic studies did not reveal the presence of urates in the tophi. The tissue reaction is analogous to that of uratic gout. The calcium deposits act as a foreign body provoking an abundant accumulation of giant cells attempting slowly and imperfectly to remove these deposits. The therapy consists of a diet from which calcium is largely excluded and surgical removal of the tophi.

Endarteritis Obliterans (Juvenile Gangrene). Two Cases. C. Lundh—p. 591

Gastric Resection for Chronic Gastric Ulcers—Roholm states that 130 gastric resections for ulcerative disease of the stomach or duodenum were performed at the National Hospital of Copenhagen between 1909 and 1931. Sleeve resection of the body of the stomach was performed in 40 and pylorotomy in 90. Before the lapse of twelve months after the operation, 105 patients were reexamined and were followed up for from one and one fourth to twenty-two years. Sleeve resection of the body of the stomach was given up because of too frequent formation of ulcer along the suture line. As the result of pylorotomy 69.2 per cent of the patients were cured, 81.5 were healed and improved, 18.5 had poor results and 12.2 died. The Polya method of gastric resection gave better results than the first method of Billroth. Better function after the latter appears doubtful and the method is technically difficult, especially when one finds it desirable to remove all the antral portion. The tendency to delayed emptying is greater than after the Polya method. There were three instances of recurring ulcer after pylorotomy. The author compares the results obtained after pylorotomies with those obtained after 101 gastro enterostomies reported from the same clinic by Nielsen. The author concludes that there is no apparent difference in the value of the two methods when used as a routine.

Changes in Cerebrospinal Fluid After Spinal Anesthesia—Backer-Grøndahl studied the cerebrospinal fluid of 138 patients operated on under spinal anesthesia. Spinal punctures were performed twenty-four, forty-eight and seventy-two hours after the operation. In 65 per cent of the patients, an increase in the cell count of the cerebrospinal fluid was found. This increase was present in only 30 per cent of the patients after forty-eight hours and in 18 per cent after seventy-two hours. The anesthetic substance used was either a 3 per cent solution of procaine hydrochloride in cerebrospinal fluid or a 1:1,500 solution of nupercaine in hypotonic salt solution, as advised by H. W. Jones. There was found an increase in the globulin and albumin in one third of the patients. The blood sugar content rose in 69 per cent. In 24 per cent this was found to be the

case only in the cerebrospinal fluid. The rise was negligible. The largest number of cells was 1,950 per cubic millimeter, while three had a cell count of more than 500. The lowest figures were found after nupercaine. No relationship could be established between the cell count and the drug used, the age of the patient or the extent of anesthesia. The relationship of headaches to the cell count was not definite. Only one of the three patients with a high cell count complained of headaches. The author likewise failed to establish causal relationship between headaches and an increase in albumin, globulin or sugar.

Sarcoma of Small Intestine—Magnusson states that the small intestine is one of the few organs in the human body in which sarcoma occurs more frequently than carcinoma. He was able to collect ninety-eight cases of sarcoma of the small intestine from the available literature, while according to Hellstrom the number of cases of carcinoma of the small intestine reported is seventy-three. The majority of sarcomas of the ileum occur between the ages of 21 and 50, with a slight preference for the third decade. Two different forms can be recognized microscopically, the annular and the diffuse. Microscopically the sarcomas of the small intestine are characterized by the fact that they originate from the submucosal layer. The serous coat is usually left intact over the growing tumor. The tumors form early metastases in the mesenteric lymph nodes. The rare occurrence of stenotic symptoms is emphasized. This feature finds an explanation in the existing dilatation of the intestine even at the seat of the tumor. The author reports a case of his own in which the involved segment of the intestine was excised with a wedge shaped piece of the mesentery. The tumor was diagnosed as a hemangiosarcoma with atypical vascular new formation and pronounced polymorphism of the tumor cells. The patient succumbed to metastases a few months after the operation.

*Lymphemoid Glandular Fever. J. Lange—p. 32

Pfeiffer Sepsis. Two Cases. G. Benestad—p. 51

Tuberculous Spondylitis and Regional Zoster—In Kobro's case there was roentgenologically established caries of the twelfth dorsal and the first, fourth and fifth lumbar vertebrae, with abscess in the left iliac fossa. Simultaneously with a reproduction of the abscess, zoster appeared on the anterior surface of the left thigh, from Poupert's ligament to the knee and on the medial and lateral surfaces to the midline. A relation between the zoster and the primary disorder is thought probable.

Lymphemoid Glandular Fever—One of Lange's cases was in a man, aged 22, and presented the typical lymphoglandular form. Three cases were in children. In the first, admitted under the diagnosis of scrofulosis and pseudocroup, the disturbance was mainly localized in the mediastinal glands on the right side. The next, from the same house, was characterized at the start by a necrotic throat and mouth disorder, with swelling of the glands, and was diagnosed as glandular fever and secondary sepsis, the fatal outcome is ascribed to the secondary sepsis. In the third, mild case the glandular disorder was particularly localized in the inguinal and iliac glands on the right side.

LONG CONTINUED, LOW GRADE, IDIOPATHIC FEVER

ANALYSIS OF ONE HUNDRED CASES

ARTHUR R. KINTNER, MD
MISSOULA, MONT

AND
LEONARD G. ROWNTREE, MD
PHILADELPHIA

Undoubtedly every experienced clinician has at one time or another been baffled diagnostically or therapeutically by patients suffering from long continued, low grade fever of unknown origin. The patient, although not seriously ill, realizes that she is below par and, fearful lest the fever spells impending disaster, consults her family physician, insisting on cure of the fever or at least on knowing its cause. The subsequent story of most of these patients is similar. After considerable investigation, study, and futile therapy, the patient leaves her family physician and starts on the rounds of consultants and specialists. In the vast majority of instances she visits hospital after hospital, wasting her time and substance without obtaining either satisfaction or relief.

Such cases are not rare. A hundred of these patients were subjected to careful routine examination in the Mayo Clinic from June 1919 to June 1930 and, in addition, in most instances to a careful search for foci of infection by Dr E. C. Rosenow or members of his staff without the cause of the fever being revealed. After relatively large numbers of them were seen it seemed desirable to hospitalize a group (twenty-three patients) and subject them to a specially devised routine study in order to ascertain whether or not, by more intensive investigation, the cause of the fever could be determined. In this group, in addition to repeated routine and special physical examinations, the chief of the clinical laboratory, Dr A. H. Sanford, was called in consultation in not a few instances in order that he might obtain his tests under conditions that appealed to him as optimal for success. Such patients were subjected to agglutination tests, to blood and urine cultures, to stool examinations and to any and every other test suggested by the patient's history or physical examination. Only patients with laboratory manifestations that were normal or considered insignificant are included in this report.

Our purpose in this communication is to center medical attention on this group of unfortunate patients. One hundred cases are analyzed and an attempt is made to correlate the subsequent course and subsequent diagnosis with the condition observed at the clinic in

order to ascertain the nature of the disease or syndrome, its onset, course, duration and outcome.

FEVER AND ITS PATHOGENESIS

Fever has never been adequately defined. Barbour¹ describes it as "any positive heat balance due not solely to food, exercise or environment." According to the diagnostic standards of the National Tuberculosis Association, "a temperature which persistently runs over 99.4 F when taken at least four times a day over a period of one week (by mouth five minutes) should be considered of significance and to constitute a fever." Kinghorn² believes that a temperature of 99 F is significant of organic disease provided it is taken not too soon after meals and provided the patient is not nervously excited. We are of the opinion that in the adult a continuous mouth temperature of 99 or above represents fever whether or not the patient is nervous. Furthermore, we feel that it is wiser to investigate patients with continuous low grade fever than it is to ignore the temperature or to explain it away.

Obviously in investigating patients with fever it is desirable to keep in mind the theories of the mechanism of heat regulation in the body and the ordinary diurnal changes in temperature. In any consideration of heat regulation both its production and loss must be taken into account. The temperature as measured by the thermometer represents the balance between heat production and heat loss. The normal temperature of the mouth as defined by Howell³ is 98.36 F with a diurnal variation, which may be as much as 1 degree centigrade. Temperature is usually highest between 5 and 7 p.m. and lowest between 6 and 7 a.m.

Heat production, as was first shown by Lavoisier,⁴ is the result of oxidation and chemical changes occurring mainly in the muscles and perhaps to a certain extent in the liver. Food and increased muscular activity are directly responsible for increased heat production. The adult male produces approximately 1,600 calories in twenty-four hours when the body is resting and more in accordance with increased muscular activity.

Heat is lost from the body by radiation and conduction from the skin, by evaporation of sweat from the skin, by expiration and also by the bodily excretions. Usually radiation and conduction from the skin account for about 75 per cent of the total daily heat loss. The other sources account for 14.5, 10.7 and 1.8 per cent, respectively.

From the Mayo Clinic, the Western Montana Clinic, the Philadelphia Institute for Medical Research and the Philadelphia General Hospital.

The body temperature represents one of the body constants, hence its regulation is of importance. Heat regulation involves a physical or physiologic mechanism that suffices in environmental temperature above 15 C (59 F) and a chemical mechanism concerned mostly in additional heat production induced through increased muscular tone or muscular contraction (shivering), which is called into play below 15 C. The endocrine glands also play a role through control of the rate of oxidation in the body and possibly, as Swingle has intimated, through control of the blood and plasma volume, which secondarily concerns heat distribution in the body. In recent years the importance of water in relation to heat regulation and fever has been considerably emphasized, fever being ascribed by Balcar, Sansum and Woodyatt⁵ to a deficit of free water in the organism.

Barbour has summed up the general evidence concerning fever in the following manner:

Accepting the water balance as the central factor in fever, we are obliged to correlate its behavior with that of the nervous heat-regulating mechanism. In the infectious fevers some such process as the following takes place. As the provocative poison reaches the tissues (perhaps the muscles in particular) catabolic changes are initiated which increase the affinity of the muscles for water. This general demand on the blood for water tends to reduce the blood volume, especially at the expense of surface blood. The skin immediately becomes cooler, and this arouses the nervous regulation against cold thus exaggerating the process of vasoconstriction and hemoconcentration. This continues until the blood becomes warm enough for the nervous system to interpret the temperature as comfortable or neutral.

NEUROGENIC FEVER AS A CLINICAL ENTITY

There are many observers who believe in the existence of a low grade fever, primarily neurogenic in origin. By some, this has been termed psychogenic fever. It is thought to be the result of various types and degrees of psychic stimuli acting on an unstable heat-regulating center. This explanation of the unstable heat-regulating center has been adopted particularly by pediatricians. These questions have been discussed by Talbot,⁶ Frankel,⁷ Neilson, Cannon,⁸ Courtiere,⁹ Deutsch,¹⁰ Egger,¹¹ Horder,¹² and Falcon-Lesses and Proger,¹³ Deutsch believing that fever may be produced by anything that stimulates the vasomotor system and that many people who have a constant fever have a psychic disturbance. Egger has seen cases of vasomotor neurosis with fever lasting many years. He thinks that fever is instituted by a vasomotor or heat-regulating center. Falcon-Lesses believed that he produced fever in three patients through various types of psychic stimulation. He concluded that it was psychogenic in origin. While it is true, as will be shown, that long-continued low grade fever is associated frequently with stigmas of neurosis, it will likewise be demonstrated that the fever persisted in still more individuals in whom no neurogenic basis could be found.

It is obvious, of course, that the labeling of such fever as of neurogenic or psychogenic origin accomplishes nothing for either the patient or the physician and serves on the other hand as a block to investigation and progress.

CLINICAL MATERIAL INVESTIGATED

In the records of the Mayo Clinic covering the period from 1919 to 1930, many such case histories were found from which a hundred were selected as the basis of this study. These conform to the following: 1 The patients were over 15 years of age. 2 Those with chills were excluded. 3 The fever and clinical manifestations persisted for at least a month prior to registration. 4 The cause of the fever after adequate investigation was recorded as undetermined. 5 Adequate data relative to the subsequent course were available.

The Height of the Fever—The mouth temperature varied from 99 to 103 F. The readings were controlled by the rectal temperature in a large series of cases. The daily range of temperature in individual cases and in different cases was quite variable.

Objection might be raised to admitting that a temperature of 99 F constitutes fever and, furthermore, that 103 F does not represent a low grade fever. However, those patients evidencing a temperature of 99 F on one day often had higher temperatures on other days. Also in the patients with high temperatures,

Age of Patients

Age	15-20	20-29	30-39	40-49	50-59	60-69	Total
Number of patients	11	30	36	12	6	5	100

chills were lacking and the course of the disease was identical with that in patients with lower grades of fever.

The Time of the Fever—It was found that 11 per cent of the patients had fever throughout the entire day and 4 per cent in the morning and afternoon. The morning rise rarely appeared until the patients had been awake from two to three hours. In the majority of cases the fever did not appear until later in the day, in 69 per cent in the afternoon, in 14 per cent in the afternoon and evening and in 2 per cent in the evening only. In approximately 90 per cent of the cases the fever developed in the afternoon and evening. This is of interest, since experience with tuberculosis shows that rest and sleep are conducive to lower temperatures and activity is conducive to the production of heat.

The Age of the Patients—The ages of the patients varied from 15 to 69 years. Sixty-six and two-thirds per cent of these patients were between 20 and 40 years of age, whereas 38 per cent of the clientele of the clinic fall between these ages. The age distribution is shown in the accompanying table.

The Sex Ratio—This is equally instructive. Females constitute almost three fourths of the entire group, 72 per cent. This also is out of keeping with the sex ratio of the clinic clientele, in which women represent 54 per cent. It would appear, therefore, that in the vast majority of instances the patient was a woman between the ages of 20 and 40 years. Under 50 years of age there were nineteen males and seventy females.

Appearance of Patients—In 65 per cent of the patients, despite the prolonged existence of fever, the physician's note stated that the patient looked healthy.

In only seven instances were they said to look sick. This obviously suggests the possibility of functional disease.

Occupation—Occupation appears to exert no influence. Fifteen various occupations were given but no significant relationships revealed.

Duration of the Fever Before Admission—Fever was the presenting symptom in ninety-five out of the hundred cases and was known to have existed from periods lasting from one month to eleven years prior to registration. The average duration for the group as a whole was 17.6 months.

Duration of the Fever After Registration—This was ascertained through correspondence with patients and their relatives and physicians. It was found that the fever had subsided in from one month to six years in a total of fifty-five cases. In forty-nine of them the mean duration after dismissal was eleven months. Thirty-eight patients continue to have fever, and seven are dead.

The Average Duration and Outcome of the Fever—It would therefore appear that, of the fifty-five patients who recovered, the fever persisted for approximately twenty-eight months, while thirty-eight patients continue to have fever and seven of them are dead.

ASSOCIATED SYMPTOMS

Three symptoms are commonly associated with this fever: exhaustion, nervousness and loss of weight. In 87 per cent of the hundred cases, exhaustion was the most pronounced accompanying symptom. In some it was mild, so that the patients were able to carry on regular work, in others it was more severe, leading to curtailment of hours or change of occupation, while in a few it was so pronounced that the patients were bed-ridden or incapable of any work whatever. The cause of the exhaustion is just as obscure as the cause of the fever. The frequency and prominence of exhaustion would seem to indicate that it is an integral part of the syndrome.

Nervousness of one form or another was given by approximately 50 per cent of the total group, and 38 per cent record loss of weight. Additional symptoms were present and are listed according to decreasing frequency in the order named: abdominal distress, pain in the back, headache, cough, palpitation and tachycardia, generalized body pains, night sweats, anorexia, dyspnea, polyuria, dysuria, menorrhagia, hemoptysis and pruritus ani.

THE ONSET OF FEVER

The onset of the fever in the majority of instances was insidious and without a known cause. Many of the patients admitted the existence of exhaustion, nervousness or other symptoms prior to the onset of the fever. However, a considerable group¹² stated specifically that their symptoms developed during or immediately after an acute infection. Fifteen said that they had had influenza, eight an acute cold, and one each some passing infection which had in the interim passed entirely out of the clinical picture. In eighteen of this group of twenty-eight the fever has disappeared.

FEROUS OR UNCONFIRMED DIAGNOSES MADE ELSEWHERE

Information regarding the diagnoses made prior to admission to the clinic was sought and reported. Tuberculosis presumably pulmonary had been diagnosed in twenty-six instances. In no case had the

bacillus of tuberculosis been demonstrated. Four of the group had had, in addition, diagnoses of Hodgkin's disease, gallbladder disease, salpingitis and Addison's disease, none of which were confirmed here or elsewhere. Fourteen others had had various unconfirmed diagnoses, while twenty-one had previously been told that no cause for the fever was apparent.

We were particularly interested in the frequency of the diagnosis of tuberculosis in so large a proportion of the cases. Tuberculosis is a serious disease and the diagnosis should not be made unless attended with certainty. The diagnosis of tuberculosis affects not only the future of the individual but frequently the offspring to the third and fourth generations. Twelve of these patients were sent to sanatoriums for tuberculosis, where they stayed for periods varying from five months to two years, without a positive diagnosis or relief in a single instance. After dismissal from the clinic in three of these twenty-six cases a diagnosis of tuberculosis was again made by the local physicians, all three patients returning to the clinic with fever but with no evidence of tuberculosis. We have not found, nor has any one else found, positive evidence of tuberculosis in a single one among these 100 patients after from two to twelve years, and we believe that tuberculosis as the cause of the fever can be legitimately excluded.

THE RÔLE OF NEUROSIS

A large number of these cases of long continued, low grade idiopathic fever were referred to the clinic with the statement from the family physician that the fever was of infectious or neurogenic origin. Others were so considered in the clinic, including such diagnoses as chronic nervous exhaustion, anxiety neurosis, neurasthenia or functional disease. These may be grouped for the sake of argument under the head of neurosis, representing in all twenty-five cases. In this group fever subsided in eleven, while in two of them the fever has persisted for more than ten years and the patients have been unable to work because of exhaustion, for which no organic basis could be discovered. It is of interest to compare these results with the results of the group in which the diagnosis of neurosis was not suggested. In the sixty-eight non-neurotic patients the fever subsided in more than 60 per cent, which would seem to indicate that the prognosis, so far as disappearance of fever is concerned, is somewhat better in those patients evidencing no manifestations of neurosis.

THE RÔLE OF FOCAL INFECTION

Every one of the hundred patients have been checked for foci of infection, and demonstrable lesions have been found at one time or another, in one or more locations, in thirty-five cases. Removal of foci was advised and followed out in all, either at the clinic or subsequently. Fever subsided in twenty-one, or 60 per cent, of these cases. This should be contrasted with the fifty cases in which no foci were found or removed, in which the fever subsided spontaneously in approximately the same proportion, 59 per cent. It seems, therefore, that the percentage of patients in whom the fever disappeared was not affected by removal of foci, as many recovering without focal removal as with focal removal. This must not be interpreted as meaning that foci of infection should not be removed but only as indicating that such procedures do not materially increase the percentage of recoveries in this syndrome.

Four patients insist that they recovered as a result of treatment directed specifically to infection, one to the removal of a gallbladder, one to the intravenous injection of gentian violet, one to roentgen treatment of the cervical lymph glands, and the fourth to treatment for Malta fever. In connection with Malta fever, it should be stated that all members of this group of 100 patients who had not been subjected to tests for agglutination for Malta fever at the clinic were requested subsequently to have the test made by their state boards of health or by the clinic through the submission of blood for immunologic studies. The patient already referred to was the only one indicating the existence of this disease.

MANAGEMENT

Since the cause of the fever is unknown, the treatment has been largely symptomatic. In many instances, an especially devised regimen has been adopted whereby the patient has systematically undergone treatment with a series of specific remedies, quinine, emetine, iodine, arsenic, and the like, with results that were very disappointing. The intravenous use of dyes has been likewise without results of significance or permanence. Foci of infection have been eradicated when recognized, neuroses have been accorded appropriate management, and general supportive measures have been adopted, all to little avail. Rest has proved helpful in the temporary control of the fever but has not been effective in securing arrest or cure.

We have found, in the management of patients suffering from this syndrome, that our familiarity with the syndrome serves to engender confidence. Our statements that we have seen many patients recover from the syndrome, that it is not due to tuberculosis, and that it does not end fatally have proved our best weapons in allaying apprehension.

PROGNOSIS

The prognosis so far as mortality is concerned is good. In the group as a whole, only seven of the patients died. In connection with the latter, two significant facts are revealed. All of these patients were over 44 years of age and all of them had lost considerable weight. It is evident, therefore, that low grade, unexplained fever in patients over 44, particularly in those who have lost weight, should be watched continuously and carefully. Three of these cases came to autopsy. One patient died of streptococcal septicemia, one of vegetative endocarditis and one of sarcoma of the kidney. In a fourth, a mass was located in the right upper quadrant prior to death. For the other three, no cause of death could be assigned. Thus malignancy accounts probably for two cases and blood stream infection for two others.

SUMMARY

One hundred cases of long continued, low grade fever of unknown origin were studied in detail in the Mayo Clinic between January 1919 and January 1930. Clinical records of these cases are analyzed in regard to age, sex, occupation, fever characteristics, associated symptoms, general appearance, neurotic tendencies and the presence of foci of infection, the course of the disease and the outcome.

1 Such fever is almost three times as frequent in the female as in the male and occurs most frequently between the ages of 20 and 40 years, at that period of life in which physical and mental strain is probably greatest.

2 The type of fever is often designated neurogenic or psychogenic—we believe without sufficient basis. Neurotic manifestations are pronounced in at least 25 per cent of the cases. Those showing neurotic stigmas are less subject to help from treatment.

3 Focal infection is present in 35 per cent of this series, but removal of foci, although often helpful in the individual case, does not increase materially the percentage of recoveries.

4 Of these patients, 93 per cent are still living, seven are dead, two of neoplasm, two of blood stream infection and three of unknown causes. Of the 55 per cent of patients who recovered, the average duration of the fever was approximately twenty-eight months.

CONCLUSIONS

The evidence relative to the cause of the fever is not clear. It may be that it is neurogenic in origin, that it is due to focal or general infection, that it results from some metabolic derangement, or that it represents a failure of heat regulation common to a group of diverse minor functional or organic derangements in the body, or it may be that it is a disease, *sui generis*. The truth is not yet evident. As we see it, the need is for further investigation rather than the too ready acceptance of an unsupportable explanation.

Thirty-Fourth and Pine streets

A CLINICAL METHOD FOR DETERMINING MODERATE DEGREES OF VITAMIN A DEFICIENCY

P. C. JEANS, M.D.

AND

ZELMA ZENTMIRE, M.S.

IOWA CITY

The accepted and easily recognized clinical evidences of vitamin A deprivation are associated only with marked degrees of vitamin A deficiency. Night blindness is one of these several clinical phenomena, but it is one that is not recognized by an ordinary routine examination and one that usually is considered only when the complaint is made by the patient. A routine test for night blindness probably would reveal many more cases than are now suspected. It might be expected also that a suitable method of examination would detect night blindness, which is present in such a mild degree that the afflicted individual is entirely unaware of its existence. Since the etiology of night blindness in these cases is presumably the same, regardless of its degree, it should be possible to detect even moderate deficiency of vitamin A by means of appropriate tests. Our purpose in this presentation is to show that the visual tests that have been employed in this study constitute a satisfactory means of determining moderate degrees of vitamin A deficiency.

EXPERIMENTAL PROCEDURE

The clinical material consisted of children who had been accepted as patients in the pediatric and orthopedic divisions of the Children's Hospital in Iowa City. No attempt at selection of cases was made, except that patients had to be physically able to walk to the room used for the tests and mentally competent to count dim

This study was assisted by a grant from Mead Johnson & Co.

spots of light in a totally darkened room. In general, the tests were made immediately after the children came under hospital care, so that the observations were the result of the home regimen rather than that of the hospital.

The instrument used in making the test was an electrically illuminated Birch-Hirschfeld photometer supplied by Carl Zeiss, Inc. This instrument consists essentially of a metal tube with a light bulb at one end, and at the other end an iris diaphragm, a five-light-point disk and a Goldberg wedge. The bulb was lighted from a 110 volt circuit controlled by a rheostat. The rheostat setting was kept practically constant and was such as to cause the bulb to glow very brightly. The iris diaphragm is opened or closed by moving a lever along a scale marked with the diameter of the opening in millimeters. The five-light-point disk is made of blackened metal and has punched out of it the five point quincunx of the throw dice. The Goldberg wedge is a glass slide treated photographically in such a manner that a gradual and uniform decrease of light transmission is obtained from end to end, with practically complete transmission at one end to zero transmission at the other. The wedge is marked with a scale of opacities, the numbers of which increase from one to thirteen.

The subject, looking at the photometer, observes its light as regulated by the wedge and the iris diaphragm and transmitted through the disk, as shown in the illustration. Because of gradations in light transmission produced by the light wedge, the light spots are unequally visible. The number of light points observed is dependent on the intensity of the light source, which in turn depends on the size of the opening through the iris diaphragm and the position of the wedge. The position of the wedge relative to the disk was not altered during a test. Light sensitivity is determined by the number of observed light spots in the five-light-point disk relative to the diaphragm opening and the wedge opacity.

The advisability of determining the foot candle power of the light from the photometer was considered. It was decided that the determination would be of no value, because the instrument is well standardized and we were dealing with light differences rather than with light quantities.

The technique of the test was worked out by the "trial and error" method but was unchanged after a satisfactory procedure was found. The test was standardized with the assistance of nine adults, who presumably had normal vision (without or with correction) and no vitamin A deficiency. The subjects were examined in a room that could be made absolutely dark. The walls were white to a height of 6 feet to facilitate bright illumination when desired, within the field of vision of the subject. Bright illumination was obtained by means of a 150 watt electric light bulb in a metal reflector supported above and behind the subject's head and so placed as to illuminate the wall faced by the subject. The subject was seated in such a position that the eyes were 60 cm. from the wedge of the photometer on a table in front of him and 100 cm. from the wall.

In the performance of the test the subject was seated comfortably in the chair. An interval timer was set for five minutes and then the moderate illumination of the room was replaced by the bright light of the 150 watt lamp. During the five minute period of exposure to the bright light the patient's intelligent cooperation was enlisted by an explanation of the plan of the test.

When the interval timer gave the five minute alarm, it was reset for ten minutes, the bright light was turned off and as quickly as possible the initial reading was made. When vision was defective, the operator frequently covered the points of light with the hand in order to avoid fatigue of the patient's eyes. When the alarm indicated the expiration of the period in darkness, the ten minute reading was taken in the same manner as the initial reading.

The liminal value of the light stimulus (end point of a reading) was taken as the point at which three constant spots of light were distinctly visible. Often five, four or three spots were temporarily visible before enough light was admitted to the eyes to permit the subject to see three constant points. The operator always confirmed the accuracy of an end point by covering the wedge with the palm of the hand for a few seconds in order to rest the patient's eyes and then by having the subject again report on the number of points of light constantly visible.

In making the test the Goldberg wedge was set at some definite point and the amount of light admitted through the instrument was controlled by means of the iris diaphragm. For the first test, immediately after the bright light had been extinguished, it was found

Schematic representation of the Birch-Hirschfeld photometer

that for the normal eye and with the wedge set at 7, the end point opening of the iris diaphragm varied from 14 to 20 mm inclusive, or, if the wedge was set at 6, the reading was 8 or 10 mm. During the ten minute period in darkness the normal eye recovered light sensitivity to the extent that, with the wedge set at 7, the end point opening of the iris diaphragm was from 3 to 6 mm inclusive. Wedge 6 was too transparent to be used for the normal eye after ten minutes in the dark.

The distance of 60 cm. from the instrument to the subject was chosen because this proved to be a convenient working distance and because to the average eye the light points are too dim at greater distances.

The time intervals were kept short, because children do not naturally remain seated quietly for more than a few minutes. The intervals chosen proved entirely satisfactory for showing definite differences between normal and abnormal eyes as regards dark adaptation.

It was desired that there should be a minimum of adjustment of the instrument in the dark. It was necessary for the examiner to learn to count the clicks of the wedge scale as it was shifted in darkness, and to count the clicks of the spring catch as the lever of the iris diaphragm was moved over its scale. When occasionally necessary to verify an adjustment in the darkness, the operator turned off the electric current and counted the clicks required to bring the Goldberg wedge or the lever of the iris diaphragm to a known point while making the excuse of resting the subject's eyes for a few seconds.

The test was so simple and so well controlled that repeated examinations gave results consistently within either the normal or the subnormal ranges, regardless of whether the subject had normal or abnormal dark adaptation. Apparently, unfamiliarity with the instrument did not influence the results. The majority of the children enjoyed the test.

A study was made of the diet preceding the examination. The information elicited was considered unsatisfactory. A reliable quantitative estimate of vitamin A intake cannot be made by questioning the subject concerning his diet.

RESULTS

Two hundred and thirty-three children were examined by this test. It was found desirable subsequently to exclude twenty from consideration. Because the tests were made immediately after the children came under observation, the unsuitability of some of the subjects for taking the test was not always immediately known. It was found that eight of the children exam-

ined were either too young or had too great an impairment of mental capacity to give reliable results. Eleven children had grossly defective vision. Ten of these were syphilitic children with chorioretinitis, optic atrophy and corneal scars from keratitis, one was a child with a marked refractive error who was tested without glasses. In all these eleven cases the children had such poor vision that it was impossible to determine whether any part of their abnormal dark adaptation was due to factors other than their physical defects. One child was excluded because he was too ill at the time of his examination to give results that represented his true state. In the course of this study it was found that falsely subnormal results were obtained from children with rising temperature, severe headache, dizziness, mydriasis or weakness such as follows tonsillectomy.

One hundred and sixty-eight of the 213 children remaining were considered to have normal recovery of light sensitivity under the conditions of the test. For 149 of these the instrument readings were within the limits determined as normal. For fifteen, slightly less light through the instrument was required for the first

reading than the standard accepted as normal, but the second reading was well within the normal limits and the recovery of light sensitivity was good. In the cases of four children, both the first and second readings were outside the normal limits, but the differences between the two showed excellent recovery of light sensitivity in the dark.

For forty-five of the children the instrument readings were of such a character as to indicate poor recovery of light sensitivity. All these children were examined by some member of the ophthalmologic staff of the hospital and in no case was there discovered any indication that the abnormality was other than functional. It was not feasible to keep all these children under observation. However, twenty-one of them were retained in the hospital and were given 3 teaspoonfuls of cod liver oil daily in addition to their regular hospital diet. Without exception, all of them subsequently showed normal results with the dark vision test. The period required for recovery varied from four days to six weeks, with an average of about twelve days. General improvement and ultimate recovery were easily detected by repeated examinations made at intervals of two or three days. No prediction could be made concerning the time required for recovery. Recovery was considered to have occurred when two successive examinations on different half days resulted in normal readings.

INTERPRETATION OF RESULTS

Functional night blindness is well established as a manifestation of vitamin A deficiency. A condition equivalent to a moderate degree of night blindness was observed in a group of children by means of the test that has been described. All the children of this group who were retained under observation subsequently showed normal dark adaptation. The recovery is interpreted as indicating that the original visual defect was functional.

Because of the accepted relationship of functional night blindness to nutrition, the occurrence of recovery while the children were ingesting a good diet with an abundance of vitamin A is believed to constitute evidence that the children of this group had been suffering from vitamin A deficiency. The facts and argument presented are believed to show that the test gives satisfactory evidence of vitamin A deficiency when the results of the test show subnormal readings and when certain recognized conditions are excluded. The conditions that warrant exclusion have been enumerated. It is believed that the test detects relatively mild degrees of vitamin A deficiency because of the short period required for recovery in some of the cases. A recovery period of four or five days would seem to warrant such a conclusion. Results obtained with the test, which are to be classed as normal, constitute evidence that the amount of vitamin A available for the generation of visual purple is adequate. However, we do not have evidence that this amount of vitamin A is optimal for good nutrition, it may be or it may not.

COMMENT

It is assumed that the children with subnormal dark adaptation who were not retained under observation would have reacted in a manner similar to that of the observed group. If this assumption is granted and the evidence is accepted as interpreted, approximately 21 per cent of the children examined had a greater or less degree of vitamin A deficiency. This incidence figure is held to be of no significance, except among children

of the same class, i. e. children of a low economic level who are physically afflicted

In the course of this study it was noted that some children with vitamin A deficiency were mentally alert and in physical appearance were well nourished, others were underweight, appeared malnourished and were sluggish physically and mentally, although not mentally deficient. Still other children appeared as though they were suffering from nutritional deficiencies, but the dark vision tests indicated no deficiency of vitamin A. It was noted, also, that in general the vitamin A deficient children who were retained under observation improved both in physical and in mental well being.

SUMMARY

A test for determining the sensitivity to light following partial dark adaptation was applied to a group of 213 children. Forty-five of them were found to have subnormal dark adaptation, and approximately half (twenty-one) were kept under observation and given a good diet, which included cod liver oil. All who were returned for study regained normal adaptation. The average period required for recovery was twelve days. There are reasons to believe that this test is satisfactory for detecting moderate degrees of vitamin A deficiency.

STUDY OF THE TREATMENT IN ACUTE TETANUS

FREDERIC W. TAYLOR, M.D.
INDIANAPOLIS

The results obtained from the treatment of active tetanus cases are far from satisfactory. Mortality statistics on this disease vary considerably from different sources but lack any constant variation that would indicate a desirability of one form of therapy over another. The only constant variation in these statistics is found in a comparison of cases with long and with short incubation periods. This is well illustrated in the cases of Calvin and Goldberg.¹ They found a mortality of 84 per cent when the incubation was less than five days, of 83 per cent when it was from five to ten days, of 37 per cent when it was from ten to fourteen days, and of 25 per cent when it was from fourteen to twenty-one days.

Until the last few years much clinical investigation has been directed toward determining the most efficacious route of administering tetanus antitoxin. Most failures following any advocated method of treatment have been attributed to an insufficient quantity of serum. The result of this reasoning has been a pyramiding of the antitoxin dosage to unbelievable heights, limited only by the amount of serum available.

This specific treatment with tetanus antitoxin regardless of the route of administration or the amount given has been strangely ineffective in bringing about any marked decrease in mortality. This is remarkable since the prophylactic use of this serum has achieved such brilliant results.

It was with the hope of gaining additional information, which might aid in the treatment of active tetanus, that this study was attempted.

The material used includes all the cases of active tetanus admitted to the Indianapolis City Hospital and

the Indiana University hospitals from 1927 to 1933. These cases were submitted to a critical examination in an attempt to analyze the treatment given and the results obtained. Certain fallacies in the treatment will be pointed out and suggestions made of improvements that might well be instituted.

The patients were quite representative of those applying to a general hospital for treatment after the onset of tetanic symptoms. Their ages ranged from 4 to 63, with 59.4 per cent between the ages of 5 and 15. During the period of our study forty-two patients were treated for tetanus. Of these, five cases were not considered in the study because of a reasonable doubt as to the correct diagnosis from either a clinical or a laboratory standpoint. The remaining thirty-seven were undoubtedly cases of tetanus. This forms a very small series but, nevertheless, one that suggests several striking deductions.

GENERAL CONSIDERATIONS

Before going further it might be well merely to mention some of the pertinent bacteriologic and physiologic aspects that the disease presents. Tetanus is a symptom and sign complex resulting from the irritant effects of tetanus toxin on the central nervous system. Toxin is elaborated from the focus of infection by the anaerobe *Clostridium tetani*. This organism will not live in healthy, sound tissue but requires either necrotic tissue or tissue that is partially devitalized. Such a devitalization is usually accomplished by the introduction of a foreign body along with the tetanus bacteria. From this focus, usually a deep penetrating wound, toxin is produced. It is believed that the toxin is picked up from the blood stream or the focus by the peripheral nerves or their lymphatics. These structures transport the toxin to the central nervous system. Here it has a particular irritative effect on the cells of the hindbrain and cord. The toxic effects are found in the cells of the lower motor neurons, but to a lesser degree. Once combined with the nerve cell, antitoxic serum cannot displace the toxin. Antitoxin neutralizes only that toxin which is free in the blood or tissues. In this limited neutralization lies its only value in cases of active tetanus.

The nerve cells of the central nervous system are hyperstimulated. These cells and the medullated nerve fibers show slight degenerative changes. However, these degenerative changes are not specific and may be seen in other toxemias. The damage produced in the nerve cells by tetanus toxin is not permanent and in this feature contrasts with poliomyelitis, in which much of the damage is permanent. The nervous lesions of tetanus apparently are entirely reversible. With recovery, even from the most desperate cases, complete restoration of function is the rule.

Death in these patients results from exhaustion, spasm of the glottis and convulsion but not from the neurologic lesion produced by tetanus toxin. Patients do not die from the disease itself, as in bulbar poliomyelitis, "but from its symptoms."² The suggestion is made in this connection that if the distributing focus and symptoms are adequately handled the disease will limit itself.

The treatment of active tetanus logically falls into three phases. These are (1) treatment of the local focus, (2) administration of appropriate sedatives and general supportive therapy, and (3) administration of specific antitoxic serum.

From the Department of Bacteriology and Pathology, Indiana University School of Medicine.

LOCAL LESION

Much has been written about the treatment of the local lesion in tetanus. Thorough careful debridement has universally been advocated. Yet, in our experience, this phase has received but little consideration compared with that directed toward the administration of antitoxin. At least, this would seem to be true in the present series. In twenty-three of the thirty-seven cases, adequate exploration was not done on admission to the hospital. In these there were sixteen deaths (69.6 per cent).

It is a frequently noted fact that the local wound in cases of tetanus may appear quite innocent or may be "healed." This attention is detracted from this initiating cause and directed toward the patient's more active symptoms. Complete local excision of this type of wound has been rightly advocated. There are still prominent texts on the subject³ which teach that "if the wound is healed it should not be disturbed." Just such a procedure was followed in seventeen of our "healed wound" cases. Of these patients, twelve died, a mortality of 70.5 per cent. It is thought that this disastrous outcome was largely due to negligence in appreciating the local wound as the distributing focus of the toxin and hence the cause of the entire tetanic syndrome.

As pointed out by others, it is astonishing how many foreign bodies are found in these innocent appearing or "healed" lesions. That these foreign bodies greatly add to the danger of the disease goes without saying. The following examples taken from our cases illustrate this point.

Two of our patients in an extremely critical condition continued a stormy and downhill course after more than a week of the most intense serum therapy. Both cases appeared to be hopeless. Then quite unexpectedly foreign bodies were extruded spontaneously from the draining wounds. In one patient this occurred nearly two weeks after hospital treatment had been instituted. Immediately after the extrusion, convulsions ceased in both patients and they started on a rapid uninterrupted course to recovery.

These cases point out strikingly the importance of a foreign body in the local wound and how it may enhance local production of toxin and bacterial growth. It seems reasonable to assume that in all cases in which the severity of the disease increases with the patient's stay in the hospital there is an inadequately treated focus that is still elaborating tetanus toxin.

In the twenty deaths, only four autopsies were allowed. These are of interest because of the conditions found in the local wounds. Two of the four cases presented wounds that were "entirely healed." When, however, these were opened and explored each contained a small foreign body surrounded by necrotic tissue and pus containing *Clostridium tetani*. The wound in the third case was not explored by the pathologist because it was "completely healed." In the fourth case a foreign body surrounded by pus and necrotic tissue was removed in the ward the day before the patient reached the autopsy table. This wound likewise yielded tetanus bacilli on culture.

These examples are given to emphasize the importance of the local wound and as an argument against the dictum that "if the wound is healed it should not be disturbed." Tetanus is caused by the local focus and continued by it. The local lesion should therefore

receive primary consideration. Active tetanus is an acute surgical emergency carrying with it a mortality far in excess of most surgical emergencies. It should be treated as such with admission to the hospital by way of the operating room.

In a discussion of the local wounds, our cases caused by "blank cartridges" should not be omitted. There were ten of these, resulting in weeping draining wounds of the hands or fingers. It has often been noted that this type of injury frequently introduces the gun wadding of the cartridge into the wound. The wadding acts as a foreign body, stimulating growth of tetanus bacilli carried in with it. Our cases emphasize this observation. Of the ten cases, eight were searched for gun wadding. In all eight cardboard wadding was found and removed. In the other two a search was not made, and both patients died.

No comment is necessary to the foregoing except perhaps the observation that all blank cartridge wounds contain gun wadding, which should be removed.

It would seem from this discussion that the most logical treatment of the local wound in cases of active tetanus is that used by Tulloch.⁴ He advocated the complete excision of the focus without entering infected tissue. At many sites, of course, this is not feasible. Here the only alternative is ample wide exploration under general anesthesia, with a careful search for debris and foreign bodies.

Opinions differ as to the relative merits of the various dressings or irrigating solutions that have been recommended. Tulloch doubts the value of any particular procedure over any other. He also questions the value of oxidizing agents, such as hydrogen dioxide. Since the wound is infected, it is probable that a hypertonic wet dressing best serves the requirements.

SEDATIVES AND GENERAL CARE

It may again be stated that all deaths in tetanus are the result of one or more of the following: convulsions, spasm of the glottis or diaphragm, exhaustion and respiratory failure. It is obvious that therapy directed to prevent these conditions is of prime importance.

In the past, hypnotics, narcotics and general anesthesia have been used to control these symptoms. Before the advent of tetanus serum, sedatives used and recommended include practically all of those listed in the Pharmacopeia and need not be mentioned. In mild cases of tetanus many of these are of considerable value. In severe cases all either lack sufficient potency or are too transient in their effect.

The ideal sedative drug should produce a quiet restful narcosis which is well sustained for a number of hours. Its physiologic effect must not be exhausting on the patient after continued use. Drugs very close to this ideal have been used in recent years as basal anesthetics and have been advocated in controlling tetanic seizures.

Sodium amytal (sodium isoamylethyl barbiturate) has been used in this capacity.⁵ Avertin (tribromoethanol) has also been used and probably enjoys a greater general popularity.⁶

Both of these drugs are relatively safe and give a well sustained narcosis. In nineteen of our cases,

3 Kirk N T Tetanus in Nelson Loose Leaf Living Surgery New York Thomas Nelson & Sons 1927 p 467A

sodium amytal was used intravenously to control symptoms. This was quite efficient and proved far more satisfactory than any other medication. There is one point in this use of sodium amytal which is worthy of note and which likewise applies to tribrom-ethanol. The tendency was to give amytal only when convulsions become severe. The drug was then withheld until convulsions again appeared. A more rational procedure would be to continue sustaining doses, keeping the patient under moderate narcosis at all times. In this way the patient might entirely escape severe tetanic seizures and large amounts of sodium amytal or tribrom-ethanol would not be necessary to restore a restful sleep.

The time-honored quiet darkened room is of great importance. It is too often either overlooked or not available. That the average tetanus patient is not kept sufficiently relaxed and quiet is well illustrated by our series. Of the twenty patients who died, fifteen (75 per cent) continued to have convulsions or rigidity up to the time of death. Nineteen of the twenty (95 per cent) were restless and not relaxed.

Since the tetanus patient frequently succumbs to exhaustion, all practical supportive therapy must be brought into action. The fluid intake should be maintained at a high level and elimination watched closely. As the patient usually cannot take sustaining amounts of fluid and nutrition by mouth, these elements must be given by other routes. For this purpose the intravenous and subcutaneous use of dextrose solution and physiological solution of sodium chloride are of invaluable aid.

ANTITOXIC SERUM

The pedestal on which tetanus serum has been placed in medicine is due entirely to its use as a prophylactic measure. Here it is surpassed by none of the specific serums. Ample proof of this was demonstrated in the World War.⁷ Because of these remarkable results, the serum has been viewed with the same faith in the treatment of active tetanus. Here, because of many complex factors, the antiserum fails to duplicate the specific action found in its prophylactic use.

The statement has been made that "tetanus antitoxic serum has done more harm than good in the treatment of active tetanus." This at first sounds like rank heresy. However, there is much truth in the fact that this specific has brought about practices that certainly are detrimental to the patient's welfare. Because of the fact that it has been considered a specific, it has been used in general practice to the exclusion of other phases of treatment. The local lesion has been neglected, as well as general supportive measures and sedatives.

The majority of recent writers have expressed the opinion that, in the care of patients who have already shown tetanic symptoms, tetanus serum is of doubtful value. Perhaps the most valuable statistics along this line have been those of Calvin and Goldberg.¹ These writers found no decrease in the mortality rate at Cook County Hospital despite the ever increasing amounts of serum used. Nor could they find any advantage of administration by one route over any other. In spite of adverse evidence as to its value, the average tetanus patient continues to be loaded with massive doses of serum. Failures are still explained on the basis of insufficient serum. Again the local wound and administration of ample sedatives receive little consideration.

In our series twenty patients died, a mortality of 54 per cent. This high rate cannot be explained because of lack of antitoxic serum. The amount given ranged from 50,000 to 420,000 units. Of twenty-three patients receiving from 50,000 to 100,000 units, twelve died (52.1 per cent). Of ten patients receiving from 200,000 to 420,000 units, two died (20 per cent). These figures would seem to indicate strongly the value of massive doses of serum. On further consideration, however, it is clear that those receiving small total amounts lived but a short time after admission to the hospital. Had their span of treatment been longer, they eventually would have received the massive aggregate doses already mentioned. It is because of this fact that statistics indicating the great value of huge doses of serum should not be accepted without further knowledge of their origin.

Our patients received rather uniform initial doses of antitoxin. These consisted in from 20,000 to 60,000 units in 89 per cent of the cases.

Serum was administered by vein, intramuscularly, and beneath the spinal meninges. All three routes were utilized in the majority of cases. In the light of our own results and those of others it would seem that no particular route holds an advantage over any other, except that intravenous and intramuscular medication make the antitoxin immediately available and there is no delay caused by slow absorption. Intravenous administration is somewhat more dangerous than intramuscular medication, because of anaphylactic reactions and probably no more effective. The intrathecal route would seem theoretically to be more desirable, since the serum causes a nonspecific inflammatory reaction about the spinal nerve roots. Experimental evidence demonstrates that this reaction prevents or retards the absorption of toxin from the nerve trunks.² Clinically no advantage is noted, and this route has the disadvantage of giving delayed absorption by the circulating blood.

A few of our patients received injections of antitoxin into and about the wound site. While this procedure may prevent the absorption of some toxin, it certainly destroys or interferes with the natural barrier of granulation tissue thrown up about the focus. When local injection is used, the serum should be infiltrated at some distance from the actual lesion where it cannot disturb this barrier. Local antitoxic serum nerve blocks have been advocated and would seem to be of considerable benefit.

As previously stated, serum is of value in neutralizing the uncombined tetanus toxin but can be of no aid in removing that already combined with nervous tissue. Much smaller amounts of serum than those generally used are amply sufficient to neutralize the free toxin of the body. In this light it would seem a more rational procedure to give from 30,000 to 60,000 units of serum when the patient is first seen. This dose might be repeated in a week or so, when a decrease of the amount of antitoxin in the tissues has occurred.

With the consideration of serum as an adjunct and not a "specific" in the treatment of active tetanus, more attention will be focused on the local lesion and general care of the patient.

COMMENT

It is hoped that the foregoing has emphasized several phases in the treatment of active tetanus cases not generally appreciated. Treatment should be directed along three well defined lines. These are, in order of their importance, (1) adequate care of the local wound (2) sedative and general care and (3) tetanus antitoxic

⁷ Golla F. Analysis of Tetanus Statistics. *Lancet* 2: 966 (Dec 29) 1917. Sanford A. H. Tetanus and the War. *Bull. Internat. A. M. Museums* Mar 1918.

serum Though mentioned separately here, these must be considered as an inseparable triad in the treatment of the disease. If emphasis is to be placed on any particular phase more than on another, I believe that sedatives and the local focus should receive that consideration rather than the use of antitoxin.

1 *Local Lesion*—Since the local wound causes the disease and continues it, prime consideration should be given to that focus. Whenever possible, immediate complete excision of the wound is recommended. When this is not possible, complete exposure and search for foreign bodies should be done under general anesthesia. The foreign body is a potent factor aiding bacterial growth and continuing the elaboration of toxin. It should not be overlooked. In active tetanus cases it must be considered that the local wound contains a foreign body until proved otherwise. This is particularly true of "blank" cartridge wounds. The local wound of tetanus is an acute surgical emergency and should be treated as such, even though the patient is later admitted to the medical wards.

2 *Sedatives and General Care*—Patients with tetanus die from "their symptoms and not from the disease itself." It therefore follows that if these symptoms can be controlled adequately the patient's chance of recovery is much greater. Tribrom-ethanol or sodium amytal is recommended to induce light narcosis. The suggestion is also made that these drugs be given at regular intervals so as to keep the patient quiet and relaxed. This would seem wiser than to use them only when the patient becomes rigid and is on the verge of a convulsion. Equally important in conserving the patient's strength with sedatives is adequate supportive care. Particular attention must be given so that fluid intake is maintained at a high level and proper elimination is effected.

3 *Tetanus Antitoxic Serum*—The high reputation that this product enjoys is due entirely to its prophylactic use. Here it is a specific in preventing the disease or at least in lengthening the incubation period. In active tetanus it is in no sense a specific, and its value is questioned by many. As the antitoxin is unable to withdraw toxin already combined with nervous tissue, its sole action is to neutralize uncombined toxin in the body. Here it may have considerable value and, until definite proof to the contrary, its use may well be continued. It seems unnecessary to administer the huge quantities used at present. It is recommended that from 30,000 to 60,000 units be given when the patient is first seen. This might be repeated if the case runs a long, protracted course. The intramuscular route of injection is perhaps the most satisfactory.

The conclusion of two workers in this field nearly forty years ago is as pertinent today as it was then: "An ounce of clean surgery is worth several pounds of serum therapy."⁸

Vitamin C—The simplest method of supplying vitamin C to young children is to give orange juice, tomato juice is also a good source, and a still cheaper one is the juice expressed from raw swede turnips. There is some clinical evidence though this is not yet conclusive that a suboptimal supply of vitamin C is by no means uncommon in Western countries, leading comparatively rarely to frank scurvy but being responsible for ill defined states of malaise and lack of energy—Colwell, S. J. *Vitamins in Clinical Medicine Practitioner* 132: 15 (Jan.) 1934.

EPIDEMIC PLEURODYNIA

ARTHUR B. RICHTER, MD

AND

HAROLD D. LEVINE, MD

BOSTON

During July, August and September 1933, twenty-four cases of epidemic pleurodynia, or "devil's grip," were admitted to the Peter Bent Brigham Hospital and are typical of cases reported in the literature, as well as of those seen at other Boston hospitals¹ and by numerous physicians in private practice in Boston during the same period.

The first outbreak of epidemic pleurodynia was reported in Virginia in 1888 by Dabney.² Since that time epidemics have been reported in New York City in 1923,³ a second one in Virginia in 1923⁴ in Philadelphia and New Jersey in 1924⁵ and in Tennessee⁶ and Massachusetts in 1925.⁷ As described in the literature⁸ the condition is characterized by the abrupt onset of excruciating pain in the chest or the epigastrium aggravated by breathing or by movement of the trunk, tenderness generally over the site of pain, an accompanying rise in temperature to from 100 to 105 F with defervescence within twenty-four to thirty-six hours, in some cases recurrence of the attack, invariable recovery, occurrence in healthy young people of either sex during the summer months and occasional occurrence of several cases in the same family, absence of important pulmonary or pleural physical signs, and a leukopenia or normal white blood cell count. While the symptoms end in many cases with a single paroxysm there is a recurrent type in which the same symptoms recur after an interval of one or more days but in milder form, the total duration being from less than a day to as long as three weeks. The symptomatology may be predominantly thoracic with localization of the pain to either side of the chest, or it may be confined to the upper part of the abdomen, often with rigidity and even simulating an acute surgical condition. The respiratory rate may be slightly or markedly accelerated and shallow. The pulse rate usually parallels the temperature rise and there may be chills, prostration, headache, pains in the extremities and back, anorexia, nausea or vomiting.

DESCRIPTION OF CASES

Twenty-four cases diagnosed as epidemic pleurodynia were observed during the summer of 1933 at the Peter Bent Brigham Hospital thirteen being ward patients and eleven patients in the outdoor department. Discussion of these cases deals only with the first group which has been more completely studied. The second group, however, represents cases similar in all respects to the first.

Characteristically the disease began abruptly with severe pain in the lower anterior portion of the chest, unilaterally or bilaterally, or in the epigastrium. Pain was generally sharp or stabbing in nature and accentuated by deep breathing or change in position. Coincidentally there was a rise in temperature to from 101 to 104 F. Three of the patients had a severe chill. Cough was extremely rare. The pulse rate rose with the temperature, varying from 90 to 135 per minute at the height of the fever, and averaging 109. At the same time, respirations varied from 22 to 70 per minute, averaging 29. The original fever varied from twelve

pain. Roentgen examination of the chest, including fluoroscopy, of eleven patients when at the height of their symptoms was negative. There was no fluoroscopic evidence of limitation of diaphragmatic excursion or of fluid in the pleural cavity.

The majority of the cases showed an elevated white blood cell count, the highest being 17,300 and the lowest 5,300, with an average of 10,400, on admission. In some previous epidemics there has been a tendency toward a leukopenia. The polymorphonuclear cells varied from 65 to 94 per cent, with an average of 77.7 per cent, the lymphocytes ranged from 7 to 27 per cent, averaging 14.3 per cent, while the monocytes varied from 1 to 16 per cent, with an average of 7.3 per cent. In no case was there an eosinophilia. No intracellular sporozoa were found. Other routine laboratory studies were not remarkable.

REPORT OF CASES

The following are typical case histories.

CASE 1—Dora W., a healthy Negro housewife, aged 28, had an uncomplicated pneumonia at 16 years. The family, past and contact histories were negative for tuberculosis. Twenty hours before admission the patient was seized with severe pain in the left lower part of the chest, radiating toward the sternum and made worse by deep inspiration. There was a short shaking chill and slight dyspnea. The temperature on admission was 101.8 F. Physical examination showed slight splinting of the left side of the chest and diminished breath sounds over the lower half of the left side of the chest, with slight dullness over this area. The left side of the diaphragm appeared to move less than the right. Deep inspiration caused excruciating pain in the left lower portion of the chest. The respiratory rate was 28 and the pulse 100 per minute. The heart was normal and the blood pressure 110 systolic and 85 diastolic. Roentgen and fluoroscopic examinations of the chest were negative. The white blood cell count was 8,900 and the blood smear showed 78 per cent polymorphonuclear leukocytes, 15 per cent lymphocytes and 7 per cent monocytes. Thirty-six hours after the onset, the temperature was normal and remained normal until discharge three days later (chart 1). Slight pain persisted on deep inspiration for twenty-four hours after the temperature reached normal. Examination of the chest eighteen

Chart 1—Fever curve in epidemic pleurodynia showing single paroxysm of fever

to seventy-two hours in duration. In about half of the cases the disease ended with a single paroxysm, but in the other half, after an interval of from twelve to twenty-four hours, the temperature again rose, with exacerbation of the symptoms. In the interval between the peaks, pain was either absent or minimal. In all cases the second and subsequent paroxysms were less severe than the first. One case was remarkable in that after the initial bout of pain and fever there was a recurrence of pain without a simultaneous rise in temperature. In the recurrent type the pain often shifted to the opposite side of the chest, to the shoulder or to the epigastrium. In about three fourths of our cases the disease lasted from five to seven days, the shortest duration was thirty-six hours and the longest seven days.

The age incidence in our group ranged from 12 to 28 years, the former being the lowest age limit in the medical service of this hospital. The youngest patient known to us was a 5 months old infant treated at the Children's Hospital.⁹

The two sexes were equally affected. It is interesting that many of the patients reported a similar illness among other members of their families or neighbors. Two of our patients were nurses. In all but a few cases, physical examination was entirely negative. In a small group however, such indefinite signs as protective splinting of the chest, slight limitation of diaphragmatic excursion, suppression of breath sounds or questionable dullness to percussion were found. Rales were never heard. In one case in which all other changes were quite typical of epidemic pleurodynia there was a transient pleural friction rub. One half of the group showed marked tenderness over the site of

Chart 2—Fever curve in epidemic pleurodynia showing primary and secondary paroxysm of fever

hours after admission showed no physical changes, except splinting with pain on deep inspiration. When seen in the outdoor department three weeks later she was well.

CASE 2—Anna B., a healthy white schoolgirl aged 14, was awakened ten hours before admission by sharp pain in both sides of the chest anteriorly, more marked on the right and aggravated by deep breathing or movement of the body. The family and past histories were irrelevant. There was no cough, only slight nausea and headache throughout the day. On admission the temperature was 102 F, the pulse 100 and the respiration rate 26 per minute. Examination was negative except for tenderness to pressure over the lower right side of the chest. Fluoroscopic examination and roentgenograms of the chest were negative. The white blood cell count was 17,300 and the blood smear showed 90 per cent polymorphonuclear leukocytes, 6 per cent lymphocytes, 4 per cent monocytes and

⁹ McKhann C F. Personal communication to the authors.

0 eosinophils. Twelve hours later the temperature had fallen to 100 F, with slight residual pain (chart 2). Twenty-four hours later the temperature again rose to 102 F with recurrence of the pain, less severe than in the first attack. The temperature then fell rapidly to normal, with complete disappearance of the pain. The temperature remained normal, except for a slight rise to 99 F on the following two days. Two weeks later the patient was well.

The first case represents a single paroxysm and the second illustrates the recurrent type. The picture is not always as clear cut as in the two cases cited and numerous cases were seen in which the diagnosis of epidemic pleurodynia could be neither made nor ruled out. For example a youth aged 18 with a history of intermittent migratory joint pains of five months' duration, complained of pain in the right side of the chest on breathing. Examination showed tenderness in the right lower portion of the chest with spasm and tenderness in the corresponding upper abdominal quadrant. The temperature was normal and roentgen examination showed limitation of the right side of the diaphragm and slight clouding of the right base. A rheumatic etiology could not be ruled out. Three other members of the same family had epidemic pleurodynia a short time previously. Such cases with complicating etiologic factors are not included in our series.

ETIOLOGY

The etiology is unknown. Small¹⁰ observed a plasmodium within the red blood cells of two patients during the epidemic described by Torrey⁶ in 1924. He designated the organism *Plasmodium pleurodyniae*. This finding has not been confirmed in subsequent epidemics. A study of an institutional epidemic by Greene³ showed that the etiologic agent is not carried in water, milk or food. All the 141 cases reported occurred in the boys' unit of the institution which was carefully isolated from the girls' unit. The epidemic appeared to be checked when quarantine was established, and the author concluded that the spread was by contact from one individual to another. Dabney² considered the possibility that the original epidemic might have been an atypical form of dengue modified by climatic difference. This was also considered by the observers of the Cape Cod epidemic in 1925.⁷ Dengue, as such, has not been recognized in New England. The plasmodium described by Small has not been found in the present epidemic.¹¹ Crone and Chapman¹ showed that the intravenous injection of blood from a patient into a normal individual produced no symptoms.

DIAGNOSIS AND TREATMENT

The epidemic nature of a disease is not generally appreciated until the similarity of a group of cases is recognized. Hence, in our own series, although epidemic pleurodynia was considered, the early cases were classified under the more common diagnosis of acute pleurisy. One must not be misled by the apparent epidemic form of chest pain and overlook the more serious forms of pleurisy. Cases of pleurisy or early pneumonia during an epidemic of pleurodynia may present no more physical changes than the latter. Patients with a diagnosis of epidemic pleurodynia should not be readily discharged as cured without further medical observation. The diagnosis is particularly difficult when the patient is first seen a day or more after the

onset when the fever may be slight or absent. It is important during an epidemic to recognize that the abdominal symptoms, particularly in children, might lead to an unnecessary operation. The difficulty in diagnosis of the individual case is not adequately stressed in the accounts of the previous epidemics. The occurrence of complications or sequelae should rule out the diagnosis of this disease. For example, the occurrence of a streptococcal empyema or acute endocarditis as sequelae as reported in the Virginia epidemic of 1923⁴ makes the original diagnosis unlikely.

The treatment in our cases was that of acute pleurisy.

THE TYPES OF HUMAN HYPERSENSITIVENESS

THEIR RELATIONSHIP TO THE LIABILITY TO
SERUM REACTIONS

J. A. RUDOLPH, M.D.

AND

MILTON B. COHEN, M.D.
CLEVELAND

The practicing physician is frequently confronted with problems that may arise following the administration of therapeutic serums. The phenomena that may occur after these injections have been variously designated as hypersensitivity, hypersusceptibility, serum disease, anaphylaxis or allergy. From the standpoint of prevention and treatment however it is as unsatisfactory or inadequate to designate all conditions that may so arise by any of these terms as it is to state that a person has tuberculosis or an enteric fever. This loose usage of these terms in most of the published reports and the placing together of all types of these reactions in one group have been the cause of much confusion and of some fatalities.¹ The physician who has a knowledge of the classification of these reactions can predict and control them satisfactorily, and fatalities can be prevented.

Serum reactions can be divided into three classes (1) immediate, (2) delayed and (3) serum sickness.

The immediate reaction occurs in from several seconds to several hours. In a moderately severe reaction an individual experiences marked apprehension and profuse sweating. Simultaneously the face becomes flushed and the eyes become congested, the lids edematous and the skin covered with urticaria. There is itching of the nose and throat, lacrimation, mucoid nasal discharge, a harsh brassy cough and difficulty in breathing associated with wheezy breath sounds. Nausea, vomiting and general prostration are frequently seen. Any or all of these phenomena may be observed as the reactions vary in severity from very mild to very severe. In fact, the reaction may be so severe that respiratory death may occur in a few minutes.

The delayed type of reaction often referred to in the literature as "accelerated serum disease" of Pirquet and Schick² occurs in from six hours to five days

following the administration of serum, the average time being from twenty-four to forty-eight hours. The symptoms resemble in all respects those of the immediate reaction. The severity, however, is much less and diminishes with the increase in time between the injection of the serum and the development of the reaction.

Serum sickness occurs in from six days to several weeks after the injection of serum. Most of the reactions occur between the seventh and the twelfth day. The reaction may be local (at the site of the injection), general or both. A typical case begins with itching swelling and urticaria at the site of the serum injection, followed within a few hours by a feeling of malaise, pain and stiffness in the joints, generalized itching with urticaria, and tender and swollen lymph glands. In addition, any of the internal organs may be involved in a reaction, giving rise in some cases to laryngeal or bronchial symptoms, in others to acute abdominal symptoms, which must be differentiated from those due to some acute intra-abdominal infection. The condition may be confused with acute rheumatic fever, because of the fever and joint manifestations, or with tetanus, because of the marked muscle stiffness.

Patients can also be divided into three classes with respect to serum reactions: (1) naturally sensitive man or man with atopy, (2) artificially sensitized, or anaphylactic man, and (3) normal man.

There is a voluminous literature dealing with the immunologic aspects of naturally sensitive and anaphylactic man. For the purpose of this paper, however, only those points having immediate clinical importance will be discussed.

Naturally sensitive man is one who has atopy. "By atopy is meant certain clinical forms of hypersensitivity that do not occur, so far as is known, in the lower animals and which are subject to hereditary influence."³ In this group have been included asthma, hay fever and eczema. It is also believed that urticaria, angioneurotic edema and certain forms of food and drug idiosyncrasy may be classified with these.

About 10 per cent of individuals have this heredity.⁴ It is now believed generally that unless an individual has this hereditary influence and background he will not develop the symptoms of atopy.

The reaction in atopy results from the union within or on the surface of body cells of specific antibodies and antigen. The reaction may occur following the first known exposure to the antigen. The antibody of atopy differs materially, as pointed out chiefly by Coca⁵ and his associates, from that participating in anaphylaxis in animals or man.

Artificially sensitized, anaphylactic, man differs from naturally sensitive man in that there is no hereditary influence determining the capacity to become sensitized and that the sensitivity follows the absorption or the injection of an antigen. There is always an incubation period between the first contact and the development of sensitivity. The sensitivity never produces asthma, hay fever, eczema, urticaria or other related clinical manifestations of atopy. The reaction occurs on the injection of the second dose of the antigen and is the result of a union between the antibody and the antigen.

The antibody differs from that found in atopy, as pointed out previously, and is identical with that of anaphylaxis, as seen in experimental animals (guinea-pig, rabbit, dog). Atopic man, like any normal man, can acquire anaphylactic sensitivity but, as pointed out previously, only man with the proper inheritance can develop atopy.

Normal man is one who has neither atopic nor anaphylactic sensitiveness. For the purpose of this discussion the terms atopic, anaphylactic and normal will be used only with respect to the antigen horse serum.

The immediate reaction may occur in man atopically or anaphylactically sensitive to horse serum. It is in the atopic individual that the serious and fatal reactions are apt to occur. In the anaphylactic individual they are usually less severe and it is in this individual that the delayed type of reaction is more likely to occur. Apparently the onset of the reaction and its severity parallel the degree of sensitiveness. This in turn varies with the size of the sensitizing dose of horse serum and the length of the incubation period. The sensitivity is usually at its height in a few weeks following the sensitizing injection and diminishes gradually thereafter, so that the longer the period following the previous injection of horse serum the less likelihood of an immediate reaction there will be following a subsequent injection. In many individuals previously anaphylactically sensitive the interval elapsing before it becomes necessary to administer a therapeutic serum is long enough to allow the sensitivity to disappear completely and the patient reacts entirely like a normal individual.

It is the normal individual who develops serum sickness uncomplicated by immediate or delayed reactions. The exact mechanism of serum sickness is not understood. The frequency of its occurrence increases with the size of the dose of serum given. It is greatest with unpurified and unconcentrated serums. In addition, serums from certain horses produce it more often than those from other horses,⁶ and there is some evidence that it occurs much more frequently when therapeutic serums (antibody containing) are given than when normal serum is given. It is also most frequent following intravenous injection.

According to published reports, some type of serum reaction occurs in from 40 to 100 per cent⁷ of individuals to whom therapeutic serums are given, depending on the size of the dose and the method of its administration. Fortunately most of these reactions are serum sickness, which, while troublesome, is usually harmless. Since, however, it occurs so frequently it is advisable to explain to some responsible person in the family whenever serum is given that serum sickness is apt to occur in a week or ten days, so that it will cause no alarm and no misunderstanding. Death in an immediate reaction occurs about once in 70,000 injections and serious reactions about once in each 10,000 injections.⁸ It is evident, therefore, that if the physician can pick out those individuals who are likely to have serious immediate reactions he need have no fear in giving therapeutic serums to all others needing it.

The most important aid in this differentiation is the history. If the patient has a history of asthma or hay fever or other atopy he belongs to the group likely to react, and this is particularly true if he is known to have symptoms on contact with horses, although before one can determine the likelihood of a reaction to horse serum it is necessary to find out whether he has atopy to this substance. The skin and eye tests are useful.

Skin tests are of two types, dermal, or scratch and intradermal. The scratch test is performed by making a linear scratch 1 cm long through the epidermis and placing on it a drop of the undiluted serum that is to be injected. A similar scratch is covered with physiologic solution of sodium chloride. A positive reaction is indicated by the development within thirty minutes of an urticarial wheal with pseudopodia surrounded by an area of erythema, in the absence of any reaction in the area covered with saline solution. If this test is negative it is safe to proceed with the intradermal test which is performed by injecting from 0.01 to 0.02 cc of a 1:100 dilution of the serum into the skin. A similar amount of physiologic solution of sodium chloride is injected into another area. A positive reaction is indicated by the development within ten minutes of an urticarial wheal with pseudopodia surrounded by an area of erythema in the absence of any change in the control. If this test is negative, a similar injection should be made with a 1:10 dilution.

The eye test is performed by placing into one conjunctival sac one drop of a 1:10 dilution in saline solution of the serum at the same time that a drop of physiologic solution of sodium chloride is placed in the other eye. A positive reaction consists of itching, lacrimation, redness of the sclera and conjunctiva, and edema of the conjunctiva and lids. This is the most important of these tests and is the one to use if only one test is to be performed.

In a patient with a history of atopy to horses in whom either the scratch, the intradermal, the eye test or all of them are strongly positive the administration of a therapeutic serum is contraindicated, as a severe reaction is almost certain to follow and it is in this type of case that death occurs.

If there is a history of atopy and these tests are negative, the patient is not atopic to horse serum and is not likely to have a severe reaction. Serum may therefore be given to such a person but precautions to be described later should be taken. Similarly patients who have previously had injections of horse serum and who give very marked reactions to the tests described may receive injections of therapeutic horse serum provided the following precautions are followed:

1. The serum should be injected subcutaneously in an extremity, the thigh or upper arm, so that the rate of absorption can be controlled by a tourniquet.

2. A tourniquet should be placed above the point of injection and should be tightened sufficiently to obstruct the venous return during the injection. One cubic centimeter should be given. The tourniquet should then be loosened but not removed and the effect of absorption observed for five minutes. If any systemic symptoms develop, the tourniquet must be tightened so that no further absorption can occur. Since that amount of reaction parallels the rate of distribution of serum to the reacting cells and this in turn depends on the rate of absorption, the reaction can be controlled by loosening the tourniquet from time to time, allowing a

rate of absorption that is below the reacting level. In addition, the effect of the previously absorbed serum may be controlled by epinephrine.

3. Before injecting serum, one should have a hypodermic syringe loaded with 1 cc of epinephrine hydrochloride solution in a dilution of 1:1,000. After tightening the tourniquet at the first sign of reaction, one should inject from 0.5 to 1 cc of the epinephrine solution intramuscularly above the tourniquet.

4. When no reaction occurs within five minutes, the remainder of the serum can be injected at one time. When there is reaction, controlled as described, the remainder of the serum should be administered in divided doses over a period of several hours, all the precautions being repeated.

"Desensitization" as a method of avoiding serum reactions has been advised by many authors and is attempted by many clinicians. It can never be carried out in the atopic patient, since "desensitization" does not occur in atopy, and any increased tolerance that might be obtained to horse serum would be to an amount infinitely smaller than the therapeutic dose of any serum. Furthermore, it requires many months to produce even this small increase in tolerance. It is also questionable whether anaphylactic man can be "desensitized" rapidly, as is evidenced by the case reports of Tuft¹⁰ and of Blankenhorn.¹¹ For clinical purposes, "desensitization" should be abandoned.

UNDULANT FEVER

ITS RELATION TO BRUCELLIASIS IN
DOMESTIC ANIMALS

L. E. STARR, DVM, MS, PhD
BLACKSBURG, VA

Brucellosis of domestic animals, or, as it is more commonly known, abortion disease, contagious abortion, infectious abortion or Bang's disease, has long been recognized as a major infectious disease of great economic importance to the live stock industry. This disease is caused by one or more of the varieties of the organisms belonging to the *Brucella* group and is prevalent throughout the entire world.

A febrile disease of man variously termed Mediterranean fever, Gibraltar fever, Corsican fever, Malta fever, undulating fever, and more recently, undulant fever is caused by the same organism that is responsible for brucellosis in domestic animals. Man acquires the disease from infected animals by ingestion of raw, contaminated dairy or meat products or by direct contact with infected animals.

The confusion in nomenclature with respect to the organism involved and the specific disease in both ani-

imals and man is unfortunate and has definitely retarded control work.

In view of the fact that *Brucella* infection occurs primarily in animals and secondarily in man, a thorough knowledge of the disease in both domestic animals and man is necessary before effective prophylactic measures can be instituted by the medical profession for the control of undulant fever.

In order to emphasize the close association of brucellosis in animals and man, a short review of the results of early investigations appears advisable.

During the past century a peculiar febrile disease of man had been noted in the Mediterranean area of southern Europe, a disease that was not typical of the usual febrile disorders such as typhoid or malaria. Marston¹ in 1861 named it Mediterranean or gastric remittent fever. A little later Bruce,² an English army physician, isolated a short coccobacillus from the spleen in a fatal case. By inoculating a monkey with this organism and recovering it, following the death of the monkey in twenty-one days, Bruce definitely proved the organism to be the causative agent of what he termed Malta fever, after the island on which many of the cases occurred.

The work that was done by Bruce has been confirmed many times. He named the organism *Micrococcus melitensis*. In honor of Bruce, the organisms belonging to this group have been given the generic name *Brucella*. By chance, members of the British royal commission who were investigating the disease in the interest of the British army garrisons stationed in that area discovered that a considerable percentage of the blood serums from the native goats reacted positively with the agglutination test. Subsequently the organism *Brucella melitensis* var. *melitensis*³ was found to be present in the blood, milk, urine, feces or uterine discharges of actively infected goats. It was also frequently found in the spleen, liver, mammae and lymph nodes at autopsy. Premature births of the young were common with infected animals. Agglutination tests of 2,000 goats on the island of Malta showed that 40 per cent reacted positively and that 10 per cent of these were eliminating the infective organism in their milk, urine or feces. Army regulations prohibiting the use of raw goat's milk by the soldiers in the garrisons resulted in an abrupt decline in the number of cases of undulant fever among the army personnel. Since the discovery of *Brucella melitensis* var. *melitensis* infection in goats in the Mediterranean area and the fact that it was transmitted from those animals to man with resultant attacks of undulant fever, similar outbreaks have been reported in Mexico and the southwestern part of the United States. *Brucella melitensis* var. *melitensis* infection of goat origin is confined principally to warm climates in which goats are raised for dairy and meat production.

At approximately the same time that Bruce and others were investigating Malta fever in the Mediterranean area, studies were being made in other parts of the world on abortion disease of cattle with no appreciation of any possible relationship between the two

diseases. Bang,⁴ a Danish veterinarian, succeeded in isolating the causative agent of abortion in cattle and proved its infectious nature by animal inoculation.

In 1911 Schroeder and Cotton⁵ reported finding abortion bacilli in milk sold on the open market and suggested that the presence of the organism in a product which was consumed in the raw state by man might result in human infection. Traum⁶ in 1914 recovered the causative agent of abortion disease in swine from an aborted fetus. Evans⁷ in 1918 demonstrated the intimate morphologic, cultural and biochemical relationship of *Brucella melitensis* var. *melitensis* and the organism recovered by Bang from cattle affected with abortion disease. This indicated the intimate if not identical relationship of the two varieties of the organism. Later investigations showed that the organism responsible for abortion in swine belonged to the same group. As the result of the investigations of Evans and others the *Brucella*-like organism originating from goats, cattle and swine came to be considered as varieties of the same genus. Since *Brucella melitensis* var. *melitensis*, which was commonly found in goats and was known to be the causative agent of undulant fever in man, was practically identical with the organism that was responsible for abortion disease in cattle and swine the thought was expressed that the latter varieties might also be the causative agent of the disease in man. In 1924 Keefer,⁸ a physician in Baltimore, reported such a case in a man with undulant fever who had had no contact in any manner with goats. Since that time many similar cases have been reported in all parts of the world, particularly in the temperate zones, in which the source of the infection could be definitely traced to either cattle or swine.

The principal varieties of the *Brucella* group are *Brucella melitensis* var. *melitensis*, *Brucella melitensis* var. *abortus*, and *Brucella melitensis* var. *suis*, which are found primarily in goats, cattle and swine, respectively. The host specificity is not absolute, since each of the varieties has been isolated from other species of animals. Unfortunately any one of the three varieties may, under favorable conditions, affect man and produce a clinical attack of undulant fever. Subvarieties have been reported but are of little importance in relation to disease production, since they are as a rule avirulent.

The *Brucella* group affects a large number of species of animals. It has been reported, either as the result of positive serologic tests or by the isolation of the specific organism, from man, goats, sheep, cattle, swine, horses, mules, asses, dogs, cats and chickens. Under experimental conditions monkeys, turkeys, ducks, geese, pigeons, pheasants, rabbits, guinea-pigs and mice have been found to be susceptible to infection.

For the diagnosis of undulant fever in man and brucellosis in animals, the agglutination and the complement fixation tests are most commonly used. Although they compare favorably in accuracy the agglutination test is generally used on account of its comparative simplicity. This test when set up and interpreted by experienced men is as reliable as any

2 Bruce David. Notes on the Discovery of a Micrococcus in Malta Fever Practitioner 30 161-170 1887.

3 According to Bergey (Manual of Determinative Bacteriology, ed. 3) the correct nomenclature is *Melalgines melitensis* (Bruce) and *Alcaligenes abortus* (Bang). In accordance with popular usage at the present time the author has adopted the nomenclature suggested by Hardy (Bulletin 155 National Institute of Health). Summarized his nomenclature reads as follows: goat variety *Brucella melitensis* var. *melitensis*; cattle variety *Brucella melitensis* var. *abortus*; swine variety *Brucella melitensis* var. *suis*.

serologic test in use today. Huddleson⁹ is using to some extent, a method of diagnosis and prognosis of the disease in man based on the principle of the opsonic index. This method, however, is not generally used at the present time. The isolation of the causative organism is desirable, but it is not practical on account of the expense, the time and the large percentage of failures, especially when the disease is due to infection with the abortus variety. Except in rare instances, both clinical symptoms and positive serologic tests are necessary for a definite diagnosis.

The occurrence of active infection and clinical disease following exposure is largely dependent on four major factors: (1) the portal of entry, (2) the virulence of the particular strain or strains of the organism involved, (3) the number of organisms and (4) the resistance of the host.

The digestive tract was formerly thought to be the principal portal of entry of the *Brucella* organism. Experimental work, however, has shown that active infection results with much greater regularity and with a smaller number of organisms following their application to the conjunctiva than by way of the digestive tract. It has been demonstrated that the organism may invade the body through either abraded or intact skin. This is of particular importance to those groups of people whose occupations bring them in frequent contact with infected animals or raw meat or milk products. The digestive tract is still regarded as one of the principal portals of entry, both in man and in animals, particularly in animal to animal infection and in consumers of raw dairy products among the human population.

The virulence of the three principal varieties is important. Since the *melitensis* variety is confined chiefly to goats, it may be disregarded in this section of the country except in rare instances. The goat population in Virginia is small, and a recent epidemiologic study of undulant fever in the state has shown that goats were not a factor in any of the cases studied.¹⁰ *Brucella melitensis* var. *melitensis* infection of goat origin is primarily confined to tropical and subtropical regions where goats are raised extensively for dairy and meat production.

Brucella melitensis var. *abortus* and *Brucella melitensis* var. *suis*, occurring in cattle and swine respectively, are the predominant strains of both animal and human subjects. The lesions produced in guinea-pigs following inoculation with virulent *Brucella melitensis* var. *suis* are usually more extensive and attended with greater mortality than those following inoculation with *Brucella melitensis* var. *abortus*. Occasional strains of *Brucella melitensis* var. *abortus*, however, have been reported which had a virulence comparable with that usually associated with the *suis* variety. Under varying conditions a virulent strain of *Brucella* may become avirulent or an avirulent one may become virulent.

Many individuals may consume milk from an infected dairy for a long period of time or care for infected cattle without showing evidence of infection. If by chance, however, an individual repeatedly gets large doses of the virulent organism, his natural resistance may be overcome, and infection and clinical disease will result.

The question of dosage is especially important with the consumers of raw dairy products. Huddleson¹¹ made bacterial counts of nine samples of infective milk, on which the cream was allowed to rise naturally at refrigeration temperature. The average count obtained was cream, 2187 *Brucella* organisms per cubic centimeter, bottom milk, 3 *Brucella* organisms per cubic centimeter and whole milk, 264 *Brucella* organisms per cubic centimeter. It is evident that an individual who used raw contaminated cream would be much more likely to become infected than one who used whole milk or skimmed milk. The use of dairy products from small dairies is more likely to result in infection for the same reason, owing to the dilution factor. With large herds, milk from the same cow does not go to the same individual every day, and the number of organisms ingested would vary.

If the infective organism has sufficient virulence and gains access to the body in sufficient numbers, it may be able to break down the natural resistance with resultant disease. If, however, the normal resistance is low as the result of some debilitating disease or a recent operation the probability of active infection under given conditions is greater. While securing case histories of undulant fever patients in Virginia, I found, in several instances that the first symptoms were noted shortly following appendectomy, tonsillectomy or some unusual exposure.

Morales-Otero¹² has shown by experiments with human volunteers that infection occurred more readily through the abraded skin than through the digestive tract. Relatively large single doses of the organism that had been isolated for some time produced infection through the abraded skin, while the same cultures, when fed repeatedly in large doses, did not produce infection. Swine varieties were found to be more virulent than bovine and produced infection through the digestive tract when fed in smaller doses than the latter. Morales-Otero was unable to produce infection through the unabraded skin of man, but he did not consider this result conclusive.

Regardless of what the portal of entry may be, the organism penetrates the tissues of the body and enters the blood or lymph streams, remains there but a short time, and then localizes in some organ or organs. It possesses the ability to penetrate the normal mucosa of the digestive tract, the normal conjunctiva, the vaginal mucous membrane, the urethra or the epithelium of the skin.

In cattle and swine the organism has a peculiar affinity for the reproductive organs and the neighboring lymph nodes. Foci of infection, however, may be found in other organs of the body, particularly the spleen and liver. Infection is rarely permanent in any of the organs of the body except in the mammary gland and regional lymph nodes, and even in these it is as a rule only transient, except in mature animals in which the mammary gland is functioning. During lactation the mammary gland offers a favorable location for reproduction, the infective organism being found in one or all four quarters. The live organism may be present in the mammary gland of cattle during the lifetime of the animal and be eliminated either intermittently or regularly in the milk. The presence of an

almost constantly lactating mammary gland in cattle offers a reservoir for the reproduction and discharge of the organism. In swine the disease tends to be transient and not permanent as it is in cattle.

Brucella infection in the human being apparently follows the same course in the body as in animals, as evidenced by frequent involvement of the reproductive tract. The periodic functioning of the mammary gland and other peculiarities of the host or of the infective organism not thoroughly understood probably preclude the gland acting as a permanent reservoir of infection.

At the time of abortion or normal pregnancy in the case of infected cattle, hogs and goats, the organism is thrown off in myriad numbers with the fetus, placenta, amniotic fluid, and subsequent uterine discharges. Animal-to-animal and animal-to-man infection is most likely to occur at this period. At the time of miscarriages in women as the result of Brucella infection, the same conditions apply. Fortunately such cases among women are rare, and even then modern hygienic practices in most cases eliminate the possibility of the transmission of infection in the human family.

Brucellosis in horses is not manifested by abortion, as is found with goats, cattle and swine but localizes principally in the ligamentum nuchae. Obstinate fistulas involving the ligamentum nuchae, the spinous processes of the cervical and thoracic vertebrae, the scapula and the contiguous structures are relatively common in horses. These fistulas are commonly known as fistulous withers or poll evil, depending on their anatomic location. The Brucella organism, either of the abortus or suis variety, has been found present in the wound discharges from a large percentage of horses so affected. Agglutination tests show most of them to react positively with Brucella antigen. Such animals, even though relatively few, are probably just as dangerous to the attendants as the positively reacting cow at the time of abortion.

Brucella infection in cattle is widespread, having been reported in almost every country in the world in which dairying is practiced. The percentage of infected animals has been found to be greatest in those sections in which dairying is the predominant industry. In such localities it is estimated that from 20 to 50 per cent of the dairy cattle are actively infected. In most of the Southern states, where the dairy industry is of minor importance, the percentage of positively reacting animals is probably much less although little investigational work has been done and with the exception of Virginia, little accurate information is available. In Virginia the proportion of infected dairy cattle is 10 per cent, which is comparatively low. This figure is based on the results of tests of 45,285 cattle. This number is approximately 10 per cent of the dairy cattle population of the state. Calculated on this basis, there are approximately 45,000 positively reacting cattle in Virginia. Experimental data indicate that from 10,000 to 25,000 of these are eliminating the live organism in their milk.

Comparative data are of interest with respect to the percentage of positively reacting cows in herds that have supplied raw dairy products to individuals who subsequently developed undulant fever and in the state as a whole. Seventeen dairy herds consisting of 362 animals that had supplied subsequent undulant fever patients with raw dairy products were tested in Virginia. Of this group 171 cattle or 47.2 per cent,

reacted positively. These results show a decided contrast with those for the state as a whole. They indicate that raw dairy products in some cases act as the transmitting agent of Brucella infection from animals to man and that such infection frequently results in undulant fever.

The results of tests for Brucella agglutinins, as previously reported,¹⁰ are shown in the accompanying tables and in the map.

TABLE 1—Results of Agglutination Tests in 1931 and 1932 for Brucella Agglutinins in Dairy Herds in Virginia as a Whole, and in Herds that Furnished Milk to People Who Subsequently Developed Undulant Fever

Human Brucella infection originating from swine has been shown to be relatively common in those states in which swine are raised extensively. This is particularly true in Iowa and other states of the corn belt. Agglutination tests of swine serums in various sections of the United States and Canada show that from 10 to 20 per cent react positively in low titers but only about 3 per cent in significant titers, that is, 1 in 100 or over. In Virginia, tests of 1,316 swine serums collected at abattoirs in Richmond, Charlottesville, Lynchburg, Harrisburg and Blacksburg showed that 312, or 23.7

per cent, reacted positively in low titers, and 42, or 3.2 per cent, in titers of 1 in 100 or over. It is evident that there is some Brucella infection in swine in Virginia. The clinical histories of the swine herds in the state, however, based on information obtained from many of the veterinarians and state regulatory officials, indicate little active infection.

Undulant fever in man may be classified in part as the result of occupational hazards and in part from ingestion of raw contaminated dairy products.

Epidemiologic data collected by various investigators indicate that approximately 40 per cent of the cases of undulant fever occur among people employed on farms

Farmers, dairymen, herdsmen and their families are exposed to infection almost daily while engaged in their occupational duties. They frequently aid cows at the time of abortion or normal parturition. Retained placentas and persistent uterine discharges are common in infected herds. While they are caring for such animals, the workers' hands and arms become soiled with infective uterine discharges or milk. The organism may penetrate the skin through scratches or abrasions on

the hands or arms or even through the normal skin if the parts are not cleansed promptly. The soiled hands may be inadvertently brushed across the eye with the result that the infection may gain entrance to the body through the conjunctiva. The same hazards are assumed in the care of brood sows at the time of parturition or for horses with fistulous withers or poll evil. The probability of infection in the case of contact with swine, however, is even greater, owing to the fact that the suis variety found in these animals is ordinarily much more virulent than the abortus variety found in cattle. Farmers, dairymen, herdsmen and their families ordinarily use raw dairy products, owing to the lack of pasteurization equipment as well as care for infected animals. Since a large proportion of market milk contains the live, virulent organism, the farm group of the population is exposed to infection not only by direct contact but by the ingestion of raw infective dairy products.

The occupations of seventy patients with undulant fever studied in Virginia are shown in table 3.

Undulant fever has been found to be comparatively common among butchers and abattoir employees. The spleen, liver, kidneys, lymph nodes, and other organs, and at times the blood of infected cattle and swine, frequently contain the live virulent organism. In addition to the organs noted, Feldman¹³ of the Mayo Foundation has recently reported that lesions involving the vertebrae of infected swine are common. Abattoir employees frequently have cuts on their hands from sharp bones or their knives. While they are handling infected meats, the infective organism may enter such breaks in the skin and set up active infection with resultant clinical attacks of undulant fever. This is especially true of employees caring for pork products.

Veterinarians are exposed to infection in its most virulent form, probably more than any other group of people. Almost daily while treating infected cattle and swine during the act of abortion or normal parturition, retained placentas, metritis and mastitis, their arms and hands are exposed to the live organism when it is in

its most virulent state. Similar contact occurs during operations on horses for fistulous withers and poll evil. That such infection does occur is indicated by the results found with agglutination tests of blood serums from veterinarians. In most cases in which tests have been made, from 50 to 60 per cent of the individuals show the presence of *Brucella* agglutinins in their blood serums. Clinical undulant fever is comparatively high among veterinarians.

Erythema brucellum, an allergic reaction characterized by a smooth or papulovesicular erythema on that part of the arm or arms that comes in contact with the female reproductive tract of infected cattle during obstetric operations, is common among veterinarians. The reaction appears shortly after contact and persists for several hours, attended by intense inflammation and itching. With the papulovesicular form the ruptured vesicles frequently become infected with the common pyogenic organisms, resulting in a troublesome skin condition. The reaction continues to appear at irregular intervals for months or even years, until the sensitization of the individual disappears.

In routine agglutination tests of human serums collected during Wassermann surveys and of serums from apparently normal individuals, a small percentage have been found to show the presence of *Brucella* agglutinins in significant titers, 1 in 100 or over, and a much larger percentage in lower titers. In most of these cases the history does not indicate that the individual has ever suffered with clinical undulant fever. Especially striking are systematic agglutination tests of the serums of institutional patients who have used raw dairy products from badly infected herds. The serums of from 20 to 40 per cent of the patients show the presence of specific *Brucella* agglutinins but only a small percentage show evidence of clinical disease. It is probable that a part of the individuals in whose serums specific agglutinins are found have had at some time subclinical attacks of the disease, which were regarded only as a slight indisposition and of little importance. It is evident that specific agglutinins may

develop in a person following ingestion of raw contaminated dairy products or by coming in direct contact with infected animals, without a recognizable clinical disease developing.

Table 4 shows the results obtained in Virginia with serologic tests of Wassermann serums, serums from abattoir employees, serums from veterinarians, and serums from women who had had miscarriages in the University Hospital at the University of Virginia.

Undulant fever was first recognized as an endemic disease in Virginia in 1927. It was made reportable by the state board of health in 1929. The records show that ninety-two cases were reported from Virginia during the period from 1927 to Jan 1, 1932. During the course of this study, eighty-seven of these cases were investigated. Five of them could not be located, nor could definite information be obtained from the physicians in charge. Sixteen patients were found not to have had symptoms indicative of undulant fever despite the fact that their serums reacted positively in some titer. There were seventy cases on which sufficiently complete information was obtained to justify their inclusion in this series.

Virginia is primarily an agricultural state, with the dairy industry playing an important role in the northern section as well as in the sections around Richmond and Norfolk. The chief agricultural activity along the eastern shore is truck raising, in the south-central section it is tobacco growing, and in the southwestern region it is sheep and beef cattle feeding. There are relatively few goats in the state, and hog raising is of minor importance. Only a few flocks of goats were tested, and no evidence of *Brucella* infection was found.

Of the seventy patients with undulant fever studied in Virginia sixty-four were white and six Negroes. Most of the cases occurred in persons between the ages of 20 and 60. Although the disease is primarily one of late adolescence and adult life, infants and aged people are occasionally affected.

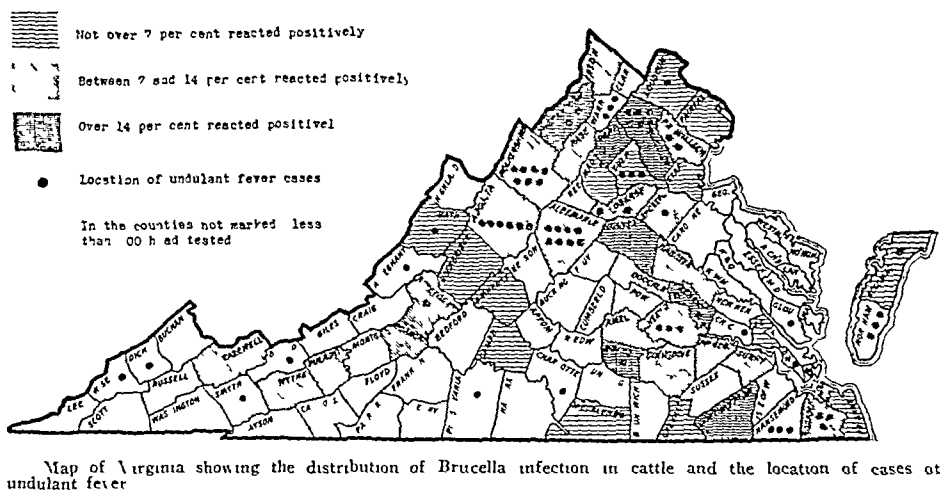

Forty-four, or 62.8 per cent, were males, and twenty-six, or 37.2 per cent, were females. The excess of males over females may be explained by the fact that a much higher percentage of men come in contact with infected animals than do women. With given conditions of exposure, the incidence of infection will be about the same for the two sexes.

The geographic location of the cases in Virginia indicates the close relationship of undulant fever with *Brucella* infection in cattle. For comparison, the location of the cases is shown on the map of Virginia on which the distribution of *Brucella* infection in cattle by counties is shown. The location of cases of undulant fever is indicated by a dot on the map. A large percentage of the cases were found to be in the northern tier of counties which correspond in general with the counties in which the greatest percentage of *Brucella* infection in cattle was found. Pasteurization of milk and cream in the larger towns and cities is evidently an important factor in the control of the disease among the consumers. On the farms and in the smaller towns pasteurization is practiced to a very limited extent.

Brucella infection is primarily a disease of animals. Of the domestic animals only goats, cattle, hogs and possibly horses are of importance in the perpetuation of the disease in nature. Man is accidentally infected either by direct contact with infected animals or their discharges or by the ingestion of raw dairy products

from infected dairy cattle or goats. It is generally considered in the United States that approximately 60 per cent of the cases of undulant fever are the result of the ingestion of raw contaminated dairy products and 40 per cent the result of direct contact with infected animals. In Virginia the source of the infection was found to be of cattle origin.

In view of the wide distribution of brucellosis in dairy cattle and the almost universal use of raw dairy products except in the larger towns and cities, it is difficult for the layman to understand why there are so few clinical cases of undulant fever. This may be explained by the following facts: 1. Most of the strains of the abortus variety originating from cattle are comparatively nonpathogenic. 2. Clinical disease results only following contact with or ingestion of, enormous doses of the abortus variety, except in the case of especially virulent strains. 3. Most people probably have some immunity, either natural or acquired. 4. Under given conditions active infection is less likely to result following ingestion of the organ-

isms than following contact through the eye or the abraded skin.

In sections of the country where hogs are raised extensively, a part of the cases have been found to be of swine origin.

In the southwestern part of the United States where goats are raised extensively which originated from the southern part of Europe, the source of infection has been shown to be largely of goat origin.

It is evident that the source or sources of infection and modes of transmission of undulant fever in the human family will vary in different geographic areas according to the prevailing local conditions of animal and dairy husbandry and the consumption of raw dairy products.

Hardy¹⁴ has reported one case of undulant fever in which the evidence suggested that the infection was secondary to a previous human case. The evidence was not regarded as conclusive. Since the live organisms may be present in the urine, feces and uterine discharges of patients with undulant fever, the attendants should exercise every precaution to prevent possible transmission of the infection.

The control and eventual eradication of undulant fever in man is dependent entirely on the control and eradication of the disease in domestic animals.

tologist and Syphilologist Mount Sinai Hospital

AND

HARRY KEIL, MD

Clinical Assistant in Dermatology Mount Sinai Hospital
NEW YORK

Codeine has been in use for the past fifty years and is today one of the most widely employed narcotics. As far back as 1832 it was extracted from opium and in 1881 its chemical formula was determined to be the methyl ester of morphine.¹ Despite its extensive use, proved cases of codeine exanthems due to hypersensitivity are rare. It is not even mentioned by Morrow² in his classic monograph on drug eruptions or by Lewin,³ although the cutaneous manifestations of morphine and opium were well known to these authors.

In 1874, Bardet⁴ studied the comparative effects of codeine, morphine and narceine. Using large doses of codeine (from 0.2 to 0.4 Gm) he found that itching occurred almost constantly in himself as well as in several patients. In two instances he noted a more or less generalized associated erythema, once in himself and once in a female who could not tolerate morphine. These are examples of overdosage of codeine rather than hypersensitivity. In 1893, Pollak⁵ reported an instance in a child, aged 1½ years, who several days after the daily ingestion of codeine (0.002 Gm a day), developed on the face pinhead papules surmounting a red base. The eruption spread to the upper part of the thorax. When the drug was withdrawn, the rash faded in one day. The author stated that this was the first example of a codeine exanthem. This observation is, however, less significant because simultaneously dilated pupils developed, a sign that implies overdosage. In the following year (1894) the first scientifically established case was described by von Essen,⁶ in whose patient, a woman, aged 31, a bright erythema developed on the inner surfaces of the arms, the lateral aspects of the trunk, the abdomen, and the inner sides of the thighs and knees. The rash occurred after the ingestion of a cough mixture containing ipecac and codeine. Only from one-third to one-half grain (0.02 to 0.03 Gm) of codeine had been taken in all. The eruption was at first associated with only slight pruritus. The codeine was removed from the cough mixture, whereupon the erythema disappeared in two days. The patient subsequently received one-third grain of codeine as a diagnostic test. Three hours later she experienced chilly sensations, followed by redness of the hands and a gradual spread of the erythema over the entire body, with the exception of the face. The eruption was of a scarlet red hue, caused intense itching and disappeared in four and a half days, leaving some desquamation. In addition, the patient received one-sixth grain (0.01 Gm) of morphine without any effect. Von Essen therefore not only proved that codeine was the cause of the exanthem but also dem-

onstrated a specific sensitivity in his case. The more recent literature contains only a few additional instances of true hypersensitivity to codeine.

Aside from these, there are several cases in which codeine has been ingested in overdosage either therapeutically, through error, or with suicidal intent. The usual result has been the occurrence of a generalized scarlatiniform eruption associated with severe itching.⁸ However, marked pruritus may be the only cutaneous manifestation,⁹ and occasionally the skin may not be affected at all, with the possible exception of profuse sweats.¹⁰

Despite the rarity of published cases, we feel that there are probably many more instances of codeine hypersensitivity, which go unrecognized merely because this drug is not generally regarded as capable of producing exanthems. The present case is reported in order to attract attention to this cause of drug eruption particularly in those obscure instances in which a scarlatiniform rash occurs. The case possesses other features of interest, which will be subsequently detailed.

REPORT OF CASE

L. H. a woman aged 48 admitted to the hospital Aug 11 1933 had been suffering from malaise anorexia, and severe constant frontal headache associated with a temperature ranging around 103 F for the past week. The onset had been sudden. On the fifth day of illness, petechial spots were noted on the chest and abdomen. On admission she appeared stuporous and acutely ill. The temperature was 105.6, the pulse rate 96 and the respiratory rate 28. Her face lips and nail beds were slightly cyanotic. Rigidity of the neck was not present. She had an occasional nonproductive cough. There was slight dullness at the right base on percussion and fine rales at both bases. The heart was slightly enlarged to the right and the sounds were distinct although of poor quality. The second aortic sound was louder than the second pulmonary sound. The spleen was not palpable. The skin presented the typical cutaneous manifestations of endemic typhus (Brill's disease) characterized by a generalized maculopapular and flat purpuric eruption over the trunk and to a lesser degree on the upper extremities inclusive of the proximal part of the right palm. The individual maculopapular lesions varied in size from a match head to a split pea and many could not be blanched on pressure. There was a suggestive subcuticular mottling. The blood count showed only a moderate secondary anemia.

The further course was characteristic of typhus fever. The rash faded completely within the next two days. By the fifteenth day of illness the temperature had dropped to normal by slow lysis at which time the headache was almost gone and the patient no longer stuporous. The blood culture and the Widal reaction were negative. A Felix-Weil reaction was positive (1:40) on admission but subsequently reached a diagnostic titer (1:320) at a time when the temperature was normal.

August 16 1 grain (0.065 Gm) of codeine was given by mouth as a sedative. That evening the patient complained of itching. On the lower part of the back and abdomen there was an erythematopapular and follicular eruption. By the following day it had spread over the entire abdomen, back and chest and now appeared as a diffuse erythema accompanied by severe pruritus. Careful inspection revealed a definite follicular arrangement with a broad zone of erythema around the individual follicles, the coalescence of which produced a scarlatiniform appearance. Within the next twenty-four hours the rash faded to a great degree but the itching persisted for another day. The diagnosis of the eruption was not clear. The original follicular character of the lesions had suggested prickly heat. The possibility of an enema rash was also considered. The

rapid spread of the eruption with its scarlatiniform appearance and the intense itching was suggestive of a drug rash but the only medicament administered had been a single dose of codeine. Moreover, no one in the medical or dermatologic departments at the time had ever personally observed an eruption after the use of codeine. Nevertheless, the original dose of this drug was repeated orally at night (10:30 p.m.). The patient could not sleep because of the resultant intense itching, and the next morning a widespread scarlatiniform rash was visible over the trunk, abdomen, lower extremities and lower half of the face. It was now clear that we were dealing with an instance of hypersensitivity to codeine. Within the following forty-eight hours the rash disappeared without any desquamation and the pruritus diminished considerably.

Three days later a patch test of codeine phosphate solution (1 grain per ounce) was applied to the right arm at 5:45 p.m. Several hours later the patient complained of a generalized pruritus, which became so severe locally that she removed the patch during the night. The following day the test area was the site of a swollen scarlet red eruption. She also complained of a mild pruritus over the remainder of the body, although there was no corresponding eruption. This could be best explained by the hypothesis that this sensitive individual had absorbed a small amount of the drug through the skin. On the following day, codeine phosphate, pantopon and opium were applied to the left forearm in powder form and Magendie solution (morphine sulphate) to the right forearm, all with negative results.

Blood was taken from the patient in an attempt to demonstrate antibodies. The serum was injected into two normal individuals, each of whom received two wheals in the left arm. About ten minutes later, a few minims of codeine phosphate solution was injected into the upper wheal. The lower one was used as a control. Within five minutes the codeine-serum site showed a marked urticarial effect with widespread erythema and striking pseudopod formation. For a moment it was thought that a positive Prausnitz-Küstner reaction had been obtained until it was found that codeine alone injected into the opposite arm produced the same erythematous-urticarial effect with pseudopod formation. Five other normal individuals reacted similarly to the intracutaneous injection of this drug. In this respect, codeine behaves very much like morphine that has been used to produce wheals artificially. In order to see the effect of the oral administration of codeine on the control serum sites of the two individuals, two doses of one-half grain each of codeine phosphate were administered. The results were negative, there was no itching, general or local, and no eruption.

Further tests were refused by the patient, whose fear of a repetition of the itching prevailed over our endeavors, so that scratch tests, quantitative intracutaneous tests with codeine and its various salts and the Urbach-Komogstein blister method for the detection of local antibodies could not be attempted.

COMMENT

Our case is an instance of true hypersensitivity to codeine, a single dose of 1 grain being sufficient to produce a generalized, severely pruritic, scarlatiniform rash. The eruption could be reproduced at will by the ingestion of the drug. An unusual feature was the positive skin patch test with codeine phosphate solution (erythematous-urticarial reaction) whereas a subsequent similar test with a solution of morphine sulphate was negative. This would seem to indicate a specific hypersensitivity to codeine, which is all the more significant since chemically the latter differs from morphine only in the possession of a methyl group. In the instance recorded by von Essen the patient developed a rash after the ingestion of codeine, whereas morphine sulphate was without effect. Occasionally, however, a patient may be sensitive to both drugs as well as to others (case 2, Wolters).

That patch tests with powders are of little value (apart from those in which the skin is simultaneously scratched with sodium hydroxide) is demonstrated by

the negative reaction to codeine phosphate powder in contrast to the positive result when the same drug was applied to the skin in solution form. A positive skin patch test in instances of drug hypersensitivity is in general very uncommon.

Since codeine appears to be excreted unchanged, the problem of antibody formation is much more simple than in the case of other drug eruptions whose existence seems to depend on decomposition products, for example, phenolphthalein eruptions. In our limited studies, we were unable to demonstrate antibodies in the blood serum, using a modified Prausnitz-Küstner technic (serum locally plus codeine by mouth). The direct Prausnitz-Küstner method (serum and codeine locally) could not be used advantageously, since codeine of itself seems normally to produce an erythematous-urticarial reaction with pseudopod formation when injected intracutaneously, imitating morphine in this respect. Unfortunately, the demonstration of local antibodies in the tissue fluids could not be attempted, a procedure that would have great theoretical interest in instances of codeine hypersensitivity. Kyrle attempted similar experiments in guinea-pigs. From his results, he concluded that the animals injected with serum from a codeine-sensitive individual reacted more strikingly to the further injection of codeine than the normal control animals. However, he admitted that these experiments were not clear cut, since guinea-pigs respond to codeine in a variable fashion. The so-called hypersensitive animals exhibited the symptoms of codeine intoxication, but in no instance could one speak of anaphylaxis. The demonstration of antibodies to codeine or to a hypothetical codeine-protein compound is still lacking.

In nearly all the instances of codeine exanthem, a scarlatiniform eruption has appeared usually within several hours after the ingestion of the drug. In general, pruritus has been associated with the eruption. Usually itching is a major symptom and in our case was so severe that the patient suffered more from its effects than from typhus fever. Itching with or without an exanthem is an almost constant symptom of codeine overdosage. It is occasionally absent in instances of codeine hypersensitivity, as in the case of Kyrle, or it may occur in a second or subsequent appearance of the rash (von Essen). In one instance (case 1, Wolters), the exudative reaction was sufficient to cause swelling of the face, hands and eyelids. In another instance (case 2, Wolters), a morbilliform eruption was reproduced in a patient who had just gone through an attack of measles. Desquamation in the wake of a codeine exanthem is a variable feature. There are no definite instances of an enanthem. When the drug is stopped, the eruption disappears in from one day to several days. If the etiology of the exanthem is unrecognized and the drug is continued, intolerable pruritus and burning of the skin occur with the development of a psychotic train of symptoms. There is no instance of death due to codeine intoxication except in that reported by Wagemann, but in that case an accidental aspiration bronchopneumonia may have been the cause of death.

In our case we were fortunate in observing the original follicular character of the eruption on the trunk. As soon as the rash takes on a generalized scarlatiniform appearance, this morphologic feature is difficult to recognize. The exanthem may be characterized as microfollicular with a broad zone of erythema around individual follicles followed by such rapid

coalescence as to produce a scarlatiniform effect. This point has been emphasized by Dittrich, who believes that the drug is probably excreted unchanged through the follicles.

In one of the cases reported by Dittrich, the eosinophil count increased to 16 per cent. Eosinophilia has been demonstrated in very few drug eruptions, the classic example being the nirvanol exanthems, in which it is practically a constant accompaniment.

SUMMARY

Our proved case of codeine exanthem due to hypersensitivity to this drug is the seventh case reported in the literature. The characteristic rash seems to be follicular in location with a broad zone of erythema around the follicles. The rapid coalescence of the erythema produces a scarlatiniform appearance. Pruritus is usually a striking symptom. An unusual feature of the case reported was the presence of a positive skin patch test. Antibodies could not be demonstrated in the blood. Further work in this direction is required, since our attempt was of necessity limited in its scope.

STUDIES OF HYPERSENSITIVENESS TO THE EMANATIONS OF CADDIS FLIES (TRICHOPTERA)

IV. DIAGNOSIS AND TREATMENT OF FORTY-THREE CASES OF ASTHMA AND HAY FEVER

SALVATORE J. PARLATO, M.D.

Director of the Asthma and Hay Fever Department, Buffalo Eye, Ear, Nose and Throat Infirmary, Wettlaufer Clinic, Attending Allergist, Millard Fillmore and Buffalo Columbus Hospitals

BUFFALO

Long before it was demonstrated that the emanations of the caddis fly cause summer asthma and hay fever,¹ these flies were known to be of some economic value. They rank very high as food for fresh water fish. Fishermen use them for bait. The federal government assists in their propagation and distribution whenever it seeks to replenish the fish supply of any fresh water body. It may do this to help the trout in some mountain river or the perch and pike of the Great Lakes. So, while a resident of any city along the Atlantic sea coast may not have contact with these flies at home, a fishing trip or a summer vacation to the Adirondacks or to the Great Lakes will expose him to the emanations of the caddis flies. An interesting example is that of a New York City physician, who reported severe hay fever and asthma while visiting on the lake shore near Erie, Pa., during the summer of 1930. Swarms of flies attracted his attention. He especially noted his symptoms when a fly happened to brush his face. He collected a number of the flies before he returned to New York. For the rest of that summer and all during the year 1931 he had no further symptoms of hay fever or asthma. The flies that were sent to me for identification were caddis flies.

My purpose in this paper is to report a series of cases of caddis fly hypersensitiveness which have been diagnosed and treated during a period of five years, 1928-1932, inclusively. The diagnosis can be made by the usual skin, ophthalmic and passive transfer tests, an aqueous extract of the whole fly being used.¹ The flies were secured from clean sources, such as the use

of insect nets near the Niagara River at night time or catching them on large pans, which were placed on a porch or veranda near an electric light. All extraneous matter was first carefully removed. With a buffered saline solution, a clear brown extract was obtained. The extract was then put up in various dilutions, the total nitrogen content being used as a guide. For routine testing, the method that Dr. Robert A. Cooke and his associates have employed very effectively in their clinic at the Roosevelt Hospital was followed, namely, solutions of 0.001, 0.01 and 0.1 mg. of nitrogen per cubic centimeter were used for the qualitative and quantitative determinations of hypersensitiveness.

Routine tests were made on 694 private patients and 156 patients in the hay fever and asthma department of the Buffalo Eye, Ear, Nose and Throat Infirmary,

Fig. 1.—Habitat and life cycle of the Caddis fly (*Trichoptera*). Its eggs are laid in any shallow fresh water. Several caddis worms are seen on the bottom of this river. A caddis pupal case is floating near the top of the water. Perched on the water lily is an adult fly (natural size) which is just emerging from the water. A moderate wind will drive the flies inland in great swarms. From a printing by Hashime Murayama after Paul Mery. Copyrighted by the National Geographic Society.

Wettlaufer Clinic. The intradermal method was used exclusively. Besides the caddis fly extract, all patients were tested with the inhalants, foods, pollens and a number of miscellaneous allergens. One was considered hypersensitive to the caddis fly only when the skin gave repeated positive reactions and then was confirmed by a positive reaction in the eye, which was produced by dropping a little of the extract on the conjunctiva. To remove any possible doubt, a little "dust" from the wings of the fly was placed on the conjunctiva and almost immediately there followed a reddening and itching of the eye with profuse lacrimation. In every instance of suspected sensitivity in which

² Personal communication to the author.

the passive transfer test was performed, the specific caddis fly reagins were readily demonstrated. Of a total of 850 allergic patients who were tested, 43 positive ones were found, an incidence rate of 5 per cent. These figures definitely establish the fact that the allergen is not rare or very uncommon.³

Fig 2—A caddis fly mounted on a glass slide shows how easily it sheds its hair and epithelial emanations. The lighter areas on both pairs of wings indicate the denuded sections. The inhalation of these fine air borne particles cause asthma, hay fever, and even hives. Reduced from a photomicrograph with a magnification of 18 diameters.

Specific treatment produced a hyposensitization or "desensitization," which clinically was evidenced by a complete or at least satisfactory relief of symptoms. The effectiveness of the treatment was put to a severe test, since most of the forty-three patients continued to

TABLE 1—Summary of Results of Specific Treatment for Caddis Fly Hypersensitivity

Number of patients treated with caddis fly extract	32
Complete or over 90% relief	23 or 72%
70 to 90% relief	7 or 22%
Less than 70% relief	2 or 6%
Number of patients who moved from caddis fly habitats (all obtained complete relief)	6
Number of patients who failed to return for treatments (whereabouts not known)	3
Number of patients who were not given specific treatments and had recurrence of symptoms studied as controls	2
Total number of fly sensitive cases	43

* These two patients did not report in time to receive a sufficient number of treatments.

live or work near the habitat of this fly. The injections of the caddis fly extract were given subcutaneously into the arm. The first dose was usually 0.05 or 0.1 cc of the weakest solution that gave a positive skin reaction. The amount was gradually increased by 0.05 or 0.1 cc, depending on the severity of the previous injection.

³ Parlato, S. J. The Sand Fly (Caddis Fly) as an Exciting Cause of Allergic Coryza and Asthma. *Ill. Its Relative Frequency.* J. Allergy 1: 307 (Mar) 1930.

The interval between the inoculations was one week for preseasonal treatment and from three to five days for patients who were seen during the fly season. Only a few constitutional reactions of moderate degree occurred following the injections, and these were promptly relieved by the administration of epinephrine. The number of doses that each patient received varied according to the degree of sensitivity and the amount of contact with the flies which could not be avoided.

TABLE 2—Results of Specific Treatment in Relation to the Caddis Fly Season

Number of patients treated during the fly season (seasonal treatment)	20
Over 90% relief	11
From 70 to 90% relief	7
Less than 70% relief	2
Number of patients treated before the fly season (preseasonal treatment)	9
Over 90% relief	9
From 70 to 90% relief	0
Less than 70% relief	0
Number of patients treated before and during the fly season (combined method)	3
Over 90% relief	3
From 70 to 90% relief	0
Less than 70% relief	0
Total number of treated cases	32

Whenever one reported late in the summer, preseasonal treatments were arranged for the spring months of the succeeding year.

Of the total forty-three diagnosed cases, thirty-two received specific treatments. The high percentage of successfully treated cases, as shown in table 1, leads one to believe that the atopic factor of the fly emanations may be compared to that of horse dander, dog hair and other well known animal air-borne excitants and not to that of the pollens of grasses and weeds which are found in the atmosphere at the same time of the year.

Fig 3—A screen of a roadside refreshment stand taken on an afternoon during the latter part of June, 1931. Within a few minutes the two panels were covered with the tiny flies. (This picture and figure 4 were made by Dr. Herbert J. Rinkel of Kansas City, Mo., while on a visit to the Niagara River with the author.)

A follow-up record of patients who were treated as far back as 1928 and 1929 shows that these patients have had no recurrence of their allergic symptoms although they received no further treatments. I am convinced that permanent relief can be achieved from a single course of treatment consisting of from fifteen to

eighteen graduated doses, which can be administered during any part of the year, preferably before the fly season (table 2)

A number of interesting facts have been elicited from a review of these caddis fly cases. There are thirty-four male and nine female patients in this series. The

Fig. 4—A close up view taken shortly after figure 3 showing how easily the flies made contact with a person standing nearby

ages ranged from 7 to 55 years, the average being 27 years. Thirty-two of the entire forty-three patients reported that their symptoms began before the age of 21. The chief complaints were as follows: Eight patients had hay fever, nine had asthma and twenty-six had hay fever and asthma. Hives and eczema were also reported in nine of these three groups. Another important diagnostic point is that every one of these patients either lived or worked near the habitat of the fly, namely, Lake Erie or the Niagara River. Moreover, it was noted that they all either had allergic symptoms or were made worse from the middle of June to about the middle of September, the time when the flies appear. As a matter of fact, twenty-six of the thirty-two treated patients applied for medical aid during these months, usually on the day after a fresh storm of flies was encountered.

This hypersensitivity is apparently readily acquired through exposure to these flies. In one case, the family history is unknown because the patient was deserted by both parents soon after birth. Fourteen, or one third, of the remaining forty-two patients reported a positive heredity, and in only one instance both parents were allergic. In striking contrast, twenty-eight, or two thirds, gave a negative family history. Cooke and Vander Veer,⁴ Spain and Cooke,⁵ Balyeat⁶ and Rowe⁷ reported a positive heredity in from 48 to 56 per cent of their allergic cases. In view of the generally accepted concept that the allergic state is inheritable and, on the other hand, that the percentage of positive family history in this series is low, there is ample justification for the belief that hypersensitivity to the caddis fly can be acquired.

A problem that allergists are confronted with every day is the management of multiple sensitive patients. Often it is difficult to decide which is the primary or most important excitant. In this series there was a total of sixteen cases in which the caddis fly was the only exciting cause. In nine others it was found to be the principal etiologic factor, while in the remaining eighteen it was considered a contributory factor. The best results with specific treatment was obtained in the first and second of these groups. In the third group, the truly multiple sensitive cases, it was necessary to augment the caddis fly treatments with injections of extracts of other air-borne excitants and with a careful rearrangement and supervision of the diet.

SUMMARY

1 The caddis fly has a wide distribution in America and Europe. The numerous lakes and rivers in the United States are the habitats of this common fly.

2 Its emanations are made up of scaly epithelium and easily identified hairs. These emanations are readily shed. They are very variable and are found in the air in considerable quantities during the summer months. Allergic symptoms are caused by the inhalation of these fine particles.

3 In a series of 850 allergic patients who were tested during the years 1928-1932 inclusive, forty-three or 5 per cent, were found to be hypersensitive to the caddis fly.

4 Thirty-two patients received inoculations of the caddis fly extract. The results indicate that specific treatment can be effectively given during as well as before the fly season, although the latter is recommended. A follow up of these patients has shown that

Fig. 5—A pollen plate was exposed in a park in Buffalo near the Niagara River. The presence of these flies in any community can be determined by looking for the crescent shaped hair on glass slides that have been exposed for twenty-four hours during any of the summer months. Reduced from a photomicrograph with a magnification of 700 diameters.

the hyposensitization or "desensitization" has endured as long as four years. It is substantially believed that one course of treatment will render a patient permanently free from allergic symptoms.

5 Caddis fly sensitivity should be remembered when one is considering the etiology or the exciting causes of

a patient whose asthma and hay fever occur or are worse during the summer months and whose residence or employment brings him in contact with these flies. It is believed that a complete diagnostic study of this group of patients will reveal additional cases of caddis fly hypersensitiveness in other sections of this country and Canada.

PROTOZOAL INFESTATIONS OF AMERICAN INDIAN CHILDREN

WILLIAM B OWEN, MA

RALPH F HONESS, MA

AND

JAMES R SIMON, MA

LARAMIE, WYO

That amebiasis and other protozoal infections are conditions not peculiar to tropical countries, but are frequently encountered in all temperate climates, is a fact amply verified wherever careful observations have been made. Through the work of Boeck and Stiles,¹ Meleney, Riley,² Faust³ and others, a large body of information has been accumulated relative to the prevalence of intestinal protozoa in the white race of the United States. Furthermore, Meleney, Bishop and Leathers⁴ have obtained considerable data on these infections in the Negro population of Tennessee.

Notwithstanding the information made available by the aforementioned studies, little is known in regard to the prevalence of these infections in the North American Indians. Two principal reasons probably account for this fact. In the first place, most of the large Indian reservations are relatively isolated from centers of research in parasitology. And, secondly, amebic dysentery is either of rare occurrence in the native Indians, or, if common, it has never commanded public attention. With these facts in mind, it seemed worth while to make a survey of some of the Indians in Wyoming for intestinal protozoa. The data here presented are the results of an examination of eighty-three Indian boys between the ages of 6 and 17 and of seven adults.

SOURCE OF MATERIAL

The individuals examined in this survey were members of the Arapahoe tribe who live on the Shoshone Indian Reservation in central Wyoming.

The sanitary and hygienic practices of these people are not unlike those found among most American Indians. The greater percentage of them live in mere shacks and only a few possess comfortable houses. Modern plumbing fixtures are not found in their homes. A few have outdoor privies, but a greater number of the families defecate in some convenient place of concealment near the home. In matters of personal cleanliness they are equally careless.

On that part of the reservation occupied by the Arapahoe tribe is located the St Stephens Mission

School for Indian children. The eighty-three boys examined were taken from the group of children in attendance at this institution, while the seven adults were residents of the vicinity.

METHODS OF STUDY

The St Stephens Mission School is located approximately 250 miles from the University of Wyoming. Fecal samples were collected in suitable containers and shipped to the zoology department of the university, where all microscopic examinations were made. The stools were from two to five days old when received in the laboratory, thus only those species of protozoa which encyst were detected. In making the microscopic examinations a technic essentially the same as that used by Meleney was employed. This method consists of emulsifying the fecal sample in water, concentrating the cyst with a centrifuge, and then staining with an iodine solution. The preparation was then examined with a Spencer binocular microscope, 15 power oculars and the 4 mm objective being used. In all doubtful infestations of *Endamoeba histolytica* fecal smears were fixed in Shaudinn's fluid and stained with iron hematoxylin.

The eighty-three boys were examined on an average of 12 times each, while only one stool sample was secured from each of the adults.

PRESENTATION OF THE DATA

An analysis of the results show that seventy-eight, or 93.9 per cent, of the eighty-three boys were positive for one or more species of intestinal protozoa. In these seventy-eight positive cases there were a total of 174 separate infestations, or an average of 2.2 species per positive case. The number of separate infestations and incidence of each species is given in table 1. Since these data are based on an average of 12 examinations per individual, the percentages are lower than the actual incidence of each species under consideration. Yet, when no attempt is made to correct the results to a six-examination basis, as Kessel and Svensson,⁵ and Faust³ have done, the incidence figures in table 1 stand

TABLE 1—Incidence of Intestinal Protozoa in Eighty-Three Indian Boys from the Arapahoe Tribe in Wyoming

Species of Protozoa	Number Infested	Percentage Infested
<i>Endamoeba coli</i>	57	68.6
<i>Iodolimax pava</i>	46	55.4
<i>Iodolimax williamsi</i>	29	34.9
<i>Endamoeba histolytica</i>	22	26.5
<i>Giardia lamblia</i>	18	21.6
<i>Chilomastix mesnili</i>	2	2.4

among the highest on record for any group of individuals to be studied in a temperate climate, and they are in many cases as high as those recorded from natives in the tropics.

The incidence for *Endamoeba histolytica*, as reported from different regions in the United States, is seldom over 10 per cent. Therefore the figure of 26.5 per cent for this species in the Indian children is extremely high and appears to be exceeded only by the data of Meleney, Bishop, and Leathers,⁴ who report an incidence as high as 41 per cent for certain communities in Tennessee. As compared with data from tropical countries, Hegner, Johnson and Stabler⁶ give 16 per

cent for 156 natives in Panama Faust and Wassell⁷ report it in 50 per cent of fifty-seven Chinese hospital patients Faust⁸ found it as high as 72.7 per cent of the population in certain unsanitated areas in Panama.

In comparing the total incidence percentages of different protozoan surveys, a figure known as the protozoan percentage incidence has come into use. This

TABLE 2.—Comparison of Percentage Positive and Average Number of Infestations per Positive Case in Various Surveys

Individuals Examined	Total Number Examined	Percentage Positive	Average Number of Infestations per Positive Case
Present survey of 83 Indian boys	83	93.9	2.00
Faust ⁸ Virginia	469	53.9	1.41
Riley ⁹ ex-service men in Minnesota	500	22.4	1.20
Faust and Wassell ⁷ Wuchang China	57	73.7	1.80
Owen ¹⁰ orphanage in Oregon	42	71.0	1.86
Boeck and Stiles ¹ United States	8,029	1.9	1.4
Boeck ⁶ industrial school children in United States	83	77.1	1.71
Hegner, Johnson and Stabler ⁵ native Panamanians	156	1.0	1.63

figure is computed from the total number of individuals examined and the total number of infestations. Thus both positive and negative cases enter into its derivation. It is believed that a better method in comparing such incidence data is to use two figures, namely the percentage positive and the average number of infestations per positive case. The percentage positive tells how general infestations are in the group examined while the average number of infestations per positive case expresses the degree of occurrence or the frequency of multiple infestations of intestinal protozoa as a whole. These two figures give in a quantitative manner both the spread and the intensity of infestations in the subjects examined. A study of these comparable data, which have been compiled from various sources and presented in table 2, reveals the significant fact that both the percentage positive and the average number of infestations per positive case are higher for the eighty-three Indian boys than for any of the other groups. The only comparable figures in the series are those of Faust and Wassell⁷ for the fifty-seven Chinese hospital patients, of Boeck⁶ for the industrial school children, and of Owen¹⁰ for the orphanage children in Oregon.

The frequency with which multiple infestations were encountered is worthy of note. A study of table 3 shows that in twenty-six cases a single protozoan species was found, in twenty-six cases two species were noted, in ten patients three species were present, in fourteen cases four species and in two cases five species were discovered. These data show that only 33 per cent of the positive individuals were harboring a single species, while 67 per cent had two or more separate infestations.

Of the seven adult Indians examined, only two were positive and both of them showed double infestations. One, a man, aged 36, was harboring *Endamoeba coli* and *Iodamoeba williamsi*. The other, a man, aged 86, was infested with *Endamoeba coli* and *Endolimax nana*. These data are not sufficient to draw any conclusions in regard to protozoan infestations in the adult Indians.

GENERAL COMMENT

Since these eighty-three Indian boys were in residence at the mission school during the period in which the examinations were made, it might be inferred that they represent typical institutional cases. However, it should be noted that they make frequent visits with their families during the period in which school is in session and all of them spend the summer months at their homes on the reservation. The mission school is equipped with every modern convenience. The children live in dormitories provided with drinking fountains and shower baths. They dine in a mess hall that reflects every aspect of cleanliness. A comparison of the sanitary and hygienic practices which the children are compelled to observe at the mission school with those prevalent among the Indian families leads to the belief that a large percentage of the positive cases are infested while at home.

The incidence of 26.5 per cent for *Endamoeba histolytica* in the eighty-three Indian boys raises the question of whether it is not of common occurrence in all the American Indian tribes. Certainly, their sanitary and hygienic practices represent optimum conditions for the propagation of all intestinal protozoa.

As regards the question of how many of the cases positive for *Endamoeba histolytica* presented a history of dysentery or other disorders symptomatic of amoebiasis, we were not able to determine. Yet it is not likely that the American Indian as a race is totally immune to the pathogenic propensities of this organism. If this is true it is indeed an exception to our knowledge of the biology of this species.

TABLE 3.—Frequency of Multiple Infestations and Various Combinations of the Six Species of Protozoa Encountered in the Eighty Three Indian Children

These data also raise the question of whether *Endamoeba histolytica* is not a contributing factor to many of the intestinal disorders so common among American Indians. Work¹¹ states that the most common disorders affecting the mass of Indians are those of the gastro-intestinal tract. These disorders, he believes, are due to faulty feeding in infancy. The data at hand offer no proof that *Endamoeba histolytica* is widely distributed among the American Indians or

11 Work Hubert. Indian Medical Service. *Mil. Surgeon* 55: 425-428 (Oct.) 1924.

that it is a contributing factor in common disorders of the gastro-intestinal tract, yet the suggestion is so apparent that physicians on the Indian reservation should bear in mind the possibility of the presence of *Endamoeba histolytica* in making a diagnosis of all obscure intestinal complaints

SUMMARY

1 Stool samples from eighty-three Indian boys of the Arapahoe tribe in Wyoming have been examined for intestinal protozoa

2 Of these patients, seventy-eight, or 93.9 per cent, were positive for one or more species of intestinal protozoa

3 These seventy-eight positive cases presented a total of 144 separate infestations, or an average of 2.2 species per positive case

4 *Endamoeba histolytica* was present in 26.5 per cent of the total number of cases examined

5 These data raise the question of whether *Endamoeba histolytica* is not widespread among the North American Indians and a contributing factor in many gastro-intestinal disorders in these people

DIPHTHERIA TOXOID

COMPARATIVE IMMUNIZING VALUE WITH AND WITHOUT ALUM, AS INDICATED BY THE SCHICK TEST

JOHN L. WHITE, M.D.

AND

EMIL A. SCHLAGETER, M.D.
CHICAGO

The work here reported was done with diphtheria toxoid furnished by Dr. William H. Park, director of laboratories and research, of the department of health of New York. Its purposes were

To test the relative immunizing value of a given diphtheria toxoid, with and without the addition of alum

To find the optimum dosage as to the amount and number of doses of both products

To establish the most desirable interval between doses for group immunization

To review the results previously obtained with commercial toxin-antitoxin in Chicago

Identical lots of diphtheria toxoid of high antigenic value were employed, to one of which 0.2 per cent of alum had been added. The dosages were a single dose of 1 cc of both alum and nonalum toxoid, two doses of 1 cc each of both products at intervals of one week, and of three weeks, and three doses of 0.5 cc, each of both reagents at intervals of one week.

The results of the tests indicate that the Park alum toxoid was somewhat more effective in producing immunity than the same lots of toxoid containing no alum. This was most noticeable in the series utilizing two doses of 1 cc each at an interval of one week.

In this series, 96.1 per cent of 295 children were immunized by the Park alum toxoid in two months, and 100 per cent of 254 children in six months, as compared with 94.6 per cent of 263 children in two months and 95.9 per cent of 213 children in six months, the same lot of Park toxoid without the alum being used.

The results likewise indicate that there is no decided advantage in using an interval of three weeks between

doses as compared with an interval of one week. The percentages in the series in which two 1 cc doses were used did not show any significant difference for either time interval in producing negative Schick reactions. Yet, for administrative purposes in the handling of groups, the shorter interval between the doses is obviously more desirable.

Three doses of 0.5 cc each of Park alum toxoid at weekly intervals were less effective than two doses of 1 cc each of a similar reagent at an interval of one week. The former series gave 94.2 per cent of immunes at two months and 96.8 per cent at six months, as compared with 96.1 per cent in two months and 100 per cent in six months in the latter series.

TABLE 1—Experiments on Park Alum Toxoid Immunizations

	Schick Test Percentage			
	Negative	Positive	Immune	Non Immune
Group 1—Given two doses 1 cc each of Park alum toxoid at an interval of three weeks				
Two months after last injection	356	13	96.5	3.5
Six months after last injection	362	7	98.1	1.9
Group 2—Given two doses 1 cc each of Park toxoid without alum at an interval of three weeks				
Two months after last injection	217	16	93.1	6.9
Six months after last injection	167	6	96.5	3.5
Group 3—Given two doses 1 cc each of Park alum toxoid at an interval of one week				
Two months after last injection	295	12	96.1	3.9
Six months after last injection	254	0	100.0	0.0
Group 4—Given two doses, 1 cc each of Park toxoid without alum, at an interval of one week				
Two months after last injection	263	15	94.6	5.4
Six months after last injection	213	9	95.95	4.05
Group 5—Given three doses 0.5 cc each of Park alum toxoid at intervals of one week				
Two months after last injection	194	12	94.2	5.8
Six months after last injection	149	5	96.8	3.2
Group 6—Given three doses 0.5 cc each of Park toxoid without alum at intervals of one week				
Two months after last injection	182	53	77.4	22.6
Six months after last injection	37	10	78.7	21.3
Group 7—Given one dose 1 cc of Park alum toxoid				
Two months after injection	173	129	50.8	49.2
Six months after injection	183	67	73.2	26.8
Group 8—Given one dose 1 cc Park toxoid without alum				
Two months after injection	116	120	49.2	50.8
Six months after injection	137	30	82.0	18.0

TABLE 2—Toxin-Antitoxin Series

	Schick Test Percentage			
	Negative	Positive	Immune	Non-immune
Given three doses of 1 cc each of commercial diphtheria toxin antitoxin at intervals of one week				
Over one year after last injection	218	85	72.0	28.0

The series in which one dose only of both reagents was used was decidedly less effective in producing the desired immunity. A single dose of the Park alum toxoid produced immunity in but 50.8 per cent in two months and 73.2 per cent in six months. The figures for the Park toxoid without alum for one dose only were 49.2 per cent in two months and 82 per cent in six months.

These lots of diphtheria toxoid, both with and without alum, when given in proper dosage, proved to be considerably more effective than three doses of the commercial toxin-antitoxin formerly used in Chicago, which in a series inoculated a year or more prior to the Schick tests, showed but 72 per cent of immunes. These treatments had been given at intervals of one week.

NEW ORLEANS

Much attention has been drawn to the outbreak of acute colitis in persons who visited Chicago from June until November 1933. Interest has been intense, owing to the severity of the colitis and the fact that the mortality rate has been so great.

Investigators who have reported thus far point to the presence of *Endamoeba histolytica* as the causative agent of this particular acute colitis.

An interesting point in these fulminating cases of dysentery has been the failure to find *Endamoeba histolytica* in the early stages of the disease. Lund and Ingham¹ reported four fatal cases of amebiasis in which the ameba, although carefully searched for, was not discovered until autopsy. In my two cases, *Endamoeba histolytica* did not make itself evident until two and one-half months after the onset of the illness. This brings out the possibility of a double infection existing, with the ameba making its appearance late. The suggestion may be that this was due to the relatively long incubation period of *Endamoeba histolytica*.

The cases to be reported were all associated with high fever, leukocytosis, prostration, and signs and symptoms of an acute condition of the abdomen. This is unusual in cases of amebiasis per se and, as expressed by Craig,² is probably due to an associated infection, usually the bacillary dysentery group. This proved to be true in my cases, in which *Bacillus dysenteriae*, described by Schorer and Duval³ in 1904, was isolated sixty days before the discovery of *Endamoeba histolytica*.

REPORT OF CASES

The mother, father, daughter and the mother's sister, all apparently well, attended the world's fair in Chicago during the early part of August 1933. During their stay there, all visited the same hotel. The sister developed an acute abdominal condition characterized by diarrhea, abdominal pain and distention, and after a few days' illness died, the cause was not determined.

CASE 1—The daughter, aged 24 years, began to complain of abdominal pain, August 30, accompanied by a fever of 100 F., nausea and vomiting. She consulted a competent surgeon that morning, who on examination found marked abdominal rigidity, with the maximum tenderness over McBurney's point. The blood count revealed 15,000 leukocytes, with 83 per cent neutrophils. That afternoon the abdominal pain became worse, with the temperature going up to 102. A second blood count revealed 17,000 leukocytes, with 89 per cent neutrophils. An appendectomy was done and whereas the appendix was edematous and injected, the surgeon was struck by the markedly inflammatory reaction in the cecum and ascending colon. He described the cecum as being dark red. The appendix was removed. The next day the patient developed a severe diarrhea. Repeated stool examinations revealed no parasites. Widal and agglutination against stock dysentery cultures were negative. September 10 she was discharged but continued to have spells of cramps and diarrhea.

Sigmoidoscopic examination revealed no injection or ulcerations in the rectum or sigmoid. In stool culture, *Bacillus dysenteriae*³ was found. This organism was agglutinated in dilutions of 1:600 against her own blood serum. Vaccine was made from this abdominal organism and administered, with complete disappearance of pain. After three weeks' time the abdominal pains returned, on another examination of stool, *Endamoeba histolytica* was found. She was given chiniofon and made an uneventful recovery.

CASE 2—The father, aged 45, first noticed griping pains in the abdomen, August 22, while on the train returning from Chicago. These pains continued during the first week in September, at which time fever and diarrhea developed. September 13 this condition forced the patient to go to bed, where he remained for about two weeks. During this time he suffered severe abdominal pains and nausea. His temperature ranged from 99 to 101. Repeated stool examinations by a competent pathologist revealed no parasites or cysts. Agglutinations against stock dysentery culture groups were negative.

After a few days of castor oil purgation, the abdominal pains were relieved and the patient returned to work but continued to have occasional griping pains.

November 11, pain in the right lower quadrant became so severe that he was forced to go to bed again. The temperature was 102, with mucus but no diarrhea. November 15 the lower right quadrant was rigid. Sigmoidoscopic examination was done but no ulcerations were found in the rectum or sigmoid. The patient was taken to Touros Infirmary, where a blood count revealed 9750 leukocytes and 69 per cent neutrophils.

Repeated stool examinations and proctoscopic smears were negative for parasites but contained pus. A culture made from the bowel smear yielded *Bacillus dysenteriae*³. This organism agglutinated against the patient's blood in dilutions of 1:600.

The patient continued to complain of pain in the lower right quadrant, and fever ranged from 99 to 103. Vaccine was started and in two weeks the abdomen became less rigid and the temperature reached normal at times during the day.

December 14 the patient again began to have griping pain in the lower part of the abdomen with daily rises of temperature to 103. A diarrhea developed and, on stool examination *Endamoeba histolytica* was found.

Under treatment with vaccine of the isolated *Bacillus dysenteriae* chiniofon and emetine, the patient made an uneventful recovery.

CASE 3—The mother, aged 45 began to suffer with indigestion and gas pains during the latter part of August. The abdomen became markedly distended and sore. No diarrhea was noted. She continued to suffer but remained on her feet until October, when she went to bed, having a temperature of 100. She remained in bed one week, felt better and again was ambulatory with only slight abdominal pains but no fever, no diarrhea and only occasional slight mucus in stools. Repeated stool examinations by a competent pathologist revealed no parasites or cysts.

November 15 pain in the right side was very severe. Abdominal rigidity and distention, with the maximum point of tenderness over McBurney's point, was associated with a temperature of 100, nausea and vomiting.

The patient was taken to Touros Infirmary, where a blood count revealed 15,000 leukocytes, with 75 per cent neutrophils. Agglutinations against stock dysentery cultures were negative. Sigmoidoscopic examinations revealed no injection or ulcerations of the rectum or sigmoid. Smears from the bowel revealed no parasites but the presence of pus. In stool culture was found *Bacillus dysenteriae*³. This organism agglutinated against the patient's blood serum in dilutions of 1:600. Vaccine was made from the isolated *Bacillus dysenteriae*.

After a few days of colonic irrigations of mild silver protein 1:1000 the patient's temperature became normal. Vaccine was given with subsequent reactions but some abdominal relief.

December 16 the patient had abdominal cramps, tenesmus and diarrhea with blood and mucus. Sigmoidoscopic examination revealed punctate ulcers in the rectum and sigmoid. Amebas in the vegetative stage were revealed in mucus from the bowel. Under treatment with vaccine, chiniofon and emetine the patient made an uneventful recovery.

DIAGNOSIS

In the presence of an epidemic of any condition associated with diarrhea, a physician must be alert for the possibility of the presence not only of amebiasis but also of the bacillary forms of dysentery. Silverman⁴ has called attention to the relative prevalence of bacillary dysentery, especially in cases of acute dysentery in which the amebas are not found.

The identification of the associated bacillary dysentery group in these cases was made by Dr. Charles Duval from stool cultures. The following is his description of the organism:

The bacteriologic examination of the stools of these patients suffering with acute dysentery reveals a specific bacillus, identical in each instance, which reacts and cross reacts positively with the blood of the various cases. It is noteworthy that the inoculated petri dishes prepared from the freshly passed mucoid stools showed after twenty-four hours' incubation at 37° C. large numbers of this organism, which were approximately two to one as compared to *B. coli* colonies on the plates.

The bacillus isolated from these cases is undoubtedly a member of the *B. dysenteriae* group. However, it is not the true Shiga or any one of the familiar mannitol fermenting strains. Cultural and serologic studies of the bacillus show a complete correspondence with the organism that was first described by Duval and Schorer in 1904, which they recovered from the dejecta of certain cases of infantile diarrhea. Though differing in certain cultural aspects the bacillus was considered by the authors as a variant or race of *B. dysenteriae* because it reacted strongly with antidyenteric serums.

The outstanding cultural difference of this bacillus from the well known members of the dysentery group is noted in litmus milk and Hiss's semisolid medium. Milk is rendered decidedly alkaline and it remains so. In the semisolid jelly of Hiss the growth, particularly for the deeper portions, spreads away from the inoculated needle path in such a striking manner as to give to the growth the appearance of an "opened umbrella" with the convexity toward the surface of the medium.

The bacillus possesses morphologic and staining properties which are identical with the Shiga bacillus of dysentery. In culture on the various sugars excepting dextrose there is no fermentation, even with acid production. In dextrose, acid is produced but no gas.

In regard to the establishment of causal relation of this bacillus to the dysentery in question it is based chiefly on the high agglutinating power of the patients' blood. The homologous isolations reacted positively in a dilution of 1:600. The patients' bloods were also tested against stock cultures of Shiga and Flexner types of *B. dysenteriae*. "Shiga" gave negative reactions, while "Flexner" reacted positively in dilutions of 1:200. This positive reaction of the patients' bloods to the Flexner bacillus is further proof that the cases are those of acute bacillary dysentery caused by the Duval-Schorer type of *B. dysenteriae*.

Surgeons who work in tropical countries have found that they must always be on their guard to avoid operation in cases of amebiasis under the diagnosis of acute appendicitis.⁵ It is important to examine stools and proctoscopic smears repeatedly for the possible presence of *Endamoeba histolytica* in vegetative or encysted forms. Also in certain cases in which every possible means have been tried to locate the ameba but of no avail, one would be justified in administering treatment for this parasite.

TREATMENT

The treatment in these cases consisted of rest in bed, a nonresidue diet and bland colonic irrigations. Vaccine made from the isolated Schorer and Duval Bacillus

dysenteriae was given in doses of 0.1 cc daily, increasing 0.1 cc daily until 1 cc is reached, and then 1 cc every four or five days for from six to eight weeks.

For the amebiasis, 1 grain (0.065 Gm.) of emetine was given for ten days along with 24 grains (1.5 Gm.) of chiniofon for ten days.

CONCLUSIONS

1 The possible cause for the failure to find *Endamoeba histolytica* early in the recently reported fatal cases of acute dysentery in the late epidemic was the relatively long incubation period of this parasite.

2 *Bacillus dysenteriae*, described by Schorer and Duval in 1904, was isolated in my cases sixty days before the discovery of *Endamoeba histolytica*.

3 Vaccine made from the isolated *Bacillus dysenteriae* proved effective in the treatment of these cases, resulting in complete abatement of signs and symptoms until relapse, at which time *Endamoeba histolytica* was found.

4 *Endamoeba histolytica* was discovered sixty days after the acute onset.

5 The combination of emetine and chiniofon proved effective against the amebiasis.

6 In every case of acute colitis, the possibility must not be overlooked of the presence of double infection, especially the association of *Endamoeba histolytica* with one of the *Bacillus dysenteriae* group.

LYMPHOGRANULOMATOSIS MALIGNA
(HODGKIN'S DISEASE)

WITH INVASION OF THE SPINAL CANAL
AND PARAPLEGIA

MELBOURNE J. COOPER, M.D.

Associate in Neurology, University of Pennsylvania School of Medicine
PHILADELPHIA

Serious involvement of the central nervous system in the course of lymphogranulomatosis maligna is a relatively well known condition, although cases proved by autopsy are of somewhat infrequent occurrence. Of the neurologic complications encountered in this disease, the most familiar ones are (a) damage to the spinal cord, presumably as a result of direct pressure caused either by extradural deposits of the abnormal granulomatous tissue or by disease of one or more vertebral bodies with consequent angulation, and (b) degeneration resulting from interference with the blood supply of the cord. Weil¹ in his recent review of the literature found that local lesions accounted for one of the aforementioned processes in 85 per cent of the cases with spinal cord involvement analyzed in his study. In an additional 7 per cent of the cases, according to his interpretation, there was scar tissue in the spinal canal, indicating to him that previously there had existed local granulomatous tissue capable of producing the cord symptoms.

Inflammatory and degenerative changes in the cord substance, without any conspicuous accumulations of granulomatous tissue in the immediate neighborhood,

have been observed in some instances, as in Forrest's² case 1, Shapiro's³ case 2, Weber's⁴ case 13, and in Weil's¹ case 3. In the last mentioned there evidently was an infectious meningitis as well. Walthard⁵ described a case with inflammatory changes, vascular thrombosis and extensive softening of the cord, the destructive process having been far greater than that which would have been expected as a result of pressure from the extradural tumor. There have been recorded widely diverse opinions as to the mechanism by which the various changes in the cord are produced in the absence of any apparent compression. For discussions of such possible mechanisms the reader is referred to the communications of Weil,¹ Shapiro,³ and Weil and Davison.⁶

The case here reported belongs to the larger group embracing the occurrence of lymphogranulomatous tissue locally, directly involving either the vertebrae, the structures within the spinal canal or those within the intervertebral foramina. It is unusual in that this single case shows both epidural and subdural lymphogranulomatous tissue, invasion of the nerve roots by outgrowths from this tissue, a direct connection by way of the nerve roots between the epidural and subdural tumor masses, invasion of blood vessels in the tumor mass by lymphogranulomatous tissue, congestion of the vessels of the cord and degeneration within the cord substance.

REPORT OF CASE

M. B., a woman, aged 39, admitted to the radiologic service of Dr. J. B. Carnett at the Philadelphia General Hospital Sept. 1, 1931, complained of paralysis of both lower limbs. About three years previously she had first noticed generalized muscular weakness and had lost some weight and the axillary lymphatic nodes had enlarged. After six months the cervical nodes had become prominent and the patient had begun to experience some shortness of breath on exertion.

The patient had been studied at the hospital of the University of Pennsylvania from May 1929 until July 1931. In that period a biopsy of a lymph node proved the diagnosis of Hodgkin's disease, and the patient was given, in the radiation therapy department, approximately 3 erythema doses of roentgen rays over the chest, anteriorly and posteriorly, from 3 to 4 erythema doses over each axilla anteriorly and posteriorly, from 3 to 4 erythema doses over each inguinal region, from 3 to 4 doses over each side of the neck, and from 1 to 2 doses over the abdomen. She improved greatly during the earlier course of this treatment. In the dermatologic department the blood Wassermann reaction was found to be strongly positive, and the patient was given five intramuscular injections of quinine bismuth iodine, 2 cc., and a total of sixteen injections of bismuth arspenamine sulphate, 0.2 Gm., in somewhat interrupted courses, owing to the irregularity of the patient's attendance. The blood Wassermann reaction became negative on one occasion and was slightly positive subsequently.

Repeated attacks of chest pains, vomiting and abdominal discomfort occurred after that, however, and there was gradual progressive abdominal distention. About three weeks prior to the admission of the patient to the Philadelphia General Hospital stiffness and weakness of the lower limbs occurred, and four or five days before admission there developed a complete paralysis of the lower limbs and incontinence of urine and feces.

The past medical history and the family history were irrelevant.

On physical examination the patient was found to be emaciated, and the anterior and posterior cervical and the supraclavicular lymphatic nodes on the left side were enlarged. The nodes on the right side were enlarged to a lesser degree, and there was moderate general lymphadenopathy. There was clinical and roentgenologic evidence of some consolidation in the upper lobe of the right lung and some ascites was present.

The erythrocyte count was 2,900,000 cells per cubic millimeter, and the leukocyte count was 9,100, the differential count showing 88 per cent polymorphonuclear forms. The blood serology tests gave a plus 2 (weakly positive) Kahn, and negative Noguchi and icebox modification tests. The examination of the cerebrospinal fluid showed an increased globulin content, no cells, negative cholesterol and Noguchi tests, and a colloidal gold curve of 2455543222.

On neurologic examination Dr. J. C. Yaskin found that there was complete paralysis of the muscles of both lower extremities including the gluteal and iliopsoas muscles. The paralyzed muscles were flaccid, the patellar and achilles reflexes of each side were diminished and there was little or no response to plantar stimulation. Vibratory sensation was lost throughout the lower extremities and the lower half of the trunk, the sensation of touch was practically lost below the eighth thoracic dermatome and that of pain below the tenth thoracic dermatome. There were, however, patchy areas below these levels in which there was some recognition of touch and of pain sensations, especially on the posterior aspect of the left thigh. The sense of position was entirely lost throughout the lower extremities.

Dr. Yaskin's diagnosis was softening of the spinal cord due to venous stasis and thrombosis brought about by the pressure of an extradural lymphogranulomatous deposit, although intramedullary infiltration was considered a possibility. Syphilis could not be ruled out but was considered to be less probable as an etiologic factor in the production of the neurologic signs.

Roentgenograms showed some rarefaction of the fourth lumbar vertebra, probably due to Hodgkin's disease, but the remainder of the spinal column was normal.

The patient died September 13. At autopsy there was found a widespread involvement of the lymphatic nodes, lungs, pancreas, spleen, kidneys, suprarenals and muscles of the back by abnormal deposits which were proved by microscopic examination to be a sclerosing type of lymphogranulomatosis maligna.

The gross examination of the spinal cord by Dr. Helena Riggs disclosed a thick tumor-like mass intimately attached to the dura mater, embracing the entire circumference of the cord in the lower cervical and upper thoracic regions. The mass was 7 cm. in length in the direction of the long axis of the spinal cord and its greatest thickness was 0.5 cm. At the point of greatest thickness of the tumor, the dura appeared invaded; the subarachnoid space could not be identified grossly, and the cord itself appeared compressed, distorted and possibly degenerated. Above and below the level of the tumor the gross appearance of the cord and its membranes was normal.

Through the kindness and cooperation of Dr. N. W. Winkelman, Dr. Riggs and the other staff members of the laboratories of the Philadelphia General Hospital I obtained serial sections of the spinal cord with the meninges and the tumor mass at two levels, supplemented by many sections from the adjacent regions of the cord. Because of the distorted relationships of the cord and the nerve roots as a result of the presence of the tumor, the exact segmental localization of these sections was uncertain, but the most pronounced involvement, which is described and illustrated, evidently affected the upper thoracic cord segments.

Microscopic examination showed that the granulomatous mass at its point of greatest development completely encircled the cord outside the dura mater and was intimately adherent to the membrane. The dura was thickened and its substance was invaded in places by the granulomatous tissue, but no penetration could be found at any point. The van Gieson stains (fig. 1) showed the integrity of the dura at the several levels. The microscopic characteristics of the tumor tissue coincided with those of the lesions found elsewhere in the body and were typical of a sclerosing type of lymphogranulomatosis maligna.

⁶ Weil Arthur, and Davison Charles, Changes in the Spinal Cord in Anemia, *Arch. Neurol. & Psychiat.* 22:966 (Nov.) 1929.

There was a background of fibrous tissue, varying in density in different areas, and in the trabeculae were cellular masses composed of fibroblasts, endothelial elements, Dorothy Reed giant cells, and lymphocytes and plasma cells. In some areas a limited amount of necrosis was seen, with occasionally a dense lymphocytic infiltration, largely though not strictly perivascular in distribution. The small and medium sized arteries showed a considerable thickening of the media and intima, with some hyalinization and some swelling and necrosis of the intima in many places. Masses of lymphogranulomatous cells were seen within the lumens of many vessels in the extradural tumor, apparently occluding these vessels.

The inner surface of the dura at one level was covered by an intimately adherent thin sheet of lymphogranulomatous tissue, extending almost completely around the cord, as extensions of the prominent nodules in the angles formed by the reflection of the dura over the entering and emerging nerve roots. The arachnoid in general seemed to be uninvolved except at its reflection over the nerve roots at the duraneural angles. In many places the intact arachnoid entirely separated from the considerable subdural masses, could be clearly identified. At no point was the substance of the cord seen to be invaded by the abnormal tissue growth, and the nerve roots themselves, although seriously invaded at the duraneural angles and distally, showed no such infiltration proximal to the angle of dural reflection.

Of particular interest was the demonstration of continuity by way of the nerve roots between the extradural tumor and the intradural nodules. Cross sections of the cord through about the middle of the tumor mass near the emerging nerve roots, showed the beginning lateral extension of the dura onto the nerve roots. Successive sections at this level showed the point of emergence of the roots from the dural canal marked by a distinct reduction in the thickness of the membrane and its continuation in attenuated form distally toward the posterior root ganglions (fig 2). Immediately distal to this termination of the true dural sac one could see numerous strands and projections of lymphogranulomatous tissue penetrating into the fibrous septums of the nerve bundles, being directly connected and traceable, on the one hand, to the extradural tumor and, on the other hand, to the intradural deposits. In longitudinal and slightly oblique sections of the roots these strands seemed to traverse the entire length of the extradural part of the nerve included in the block of tissue, i. e., from a

Fig 1—Cross section of the upper thoracic portion of the spinal cord a the encircling tumor mass b the intact dura c the nerve roots traversing the tumor d the beginning reflection of the dura over the nerve root of the opposite side. Van Gieson stain

point near the posterior root ganglion in each instance proximal to the duraneural angle.

At a somewhat higher level the roots were similarly invaded in their distal parts and near the dural reflection and there were masses of lymphogranulomatous tissue subdurally at the duraneural angles but the available block of tissue was too small to permit tracing these roots through their entire course at that level. At the periphery of the extradural tumor at

both levels, small but fairly regular and rounded isolated funiculi of nerve fibers, completely enveloped in the lymphogranulomatous mass, could be seen, evidently indicating the disorganization of the mixed peripheral nerves into separate bundles by the invading abnormal cells.

The abnormal tissue did not seem to have any tendency to invade the nerve fibers themselves or the funiculi, either in the mixed nerves, in the posterior root ganglions, or in the nerve roots within the dural sac. The vulnerable structures

Fig 2—Section through the duraneural angle a the beginning reflection of the dura onto the nerve root b the strands of lymphogranulomatous tissue accompanying the nerve roots into the subdural space c the merging of these strands distally with the extradural tumor. Toluidine blue stain

appeared to be the fibrous epineurium, the perineurium and the endoneurium, or the lymph spaces delimited by these structures, and the subdural and epidural spaces. The striking departure of the projections of lymphogranulomatous tissue from the nerve bundles immediately within the dural sac and the sheet-like spreading of the tissue around the inner surface of the dura, without distinct involvement of the arachnoid, the cord, or the intradural portions of the nerve roots proximal to the duraneural angles, suggested the affinity of the pathologic tissue for the actual or potential lymph spaces offering the least amount of mechanical resistance or other defensive reaction against invasion.

The cord substance was the seat of myelopathic changes consisting of well marked vacuolation of the white matter, with extensive swelling and disintegration of the axons, and less conspicuous degeneration of the gray matter. Somewhat more than half of the ganglion cells of the anterior and posterior horns appeared to be normal, though among the remaining cells were seen various stages of degeneration, both of the character of ischemic degeneration and of acute swelling. The glial reaction was negligible, and small perivascular collections of phagocytic cells were found only rarely. The vessels within the cord substance as well as those of the extramedullary plexus were greatly congested. The vessels accompanying the intradural portions of the nerve roots were distinctly dilated and congested, the whole picture strongly suggesting that interruption of the blood supply of the cord, as a result of compression of the spinal branches of the vertebral, ascending and deep cervical and intercostal arteries, had played an important part in the production of the acute paraplegic symptoms. The vessels of the cord did not show evidences of syphilitic disease.

COMMENT

A number of observers have considered it probable that lymphogranulomatous tissue may reach the ver-

tebral canal by growing from the diseased mediastinal and retroperitoneal lymphatic structures through the intervertebral foramina, in company with the nerve roots. Such an observation was made by Weber⁴ (case 14) and it has been demonstrated more or less

Fig. 3—Section from the extradural tumor showing the cell structure and the occurrence of masses of lymphogranulomatous cells within the lumens of the vessels. Toluidine blue stain.

convincingly in several instances in which there have been found, in the same case, invasion of the nerve roots in the intervertebral foramina and epidural deposits within the spinal canal. The cases of East and Lightwood,⁷ Delius⁸ and others⁹ are examples of such observations.

Extension of lymphogranulomatous tissue (excluding cases of Hodgkin's sarcoma) to the subdural space was found by Urechia and Goia,¹⁰ Johnston¹¹ and During,¹² and at autopsy Delius⁸ found subdural growths at the site of a previous operation. Walther⁵ implied that the inflammatory and necrotic tissue about the nerve roots, in the subarachnoid space and in the substance of the cord in his case, resembled cellular masses of lymphogranulomatous origin, but he apparently attributed the extensive degenerative changes in the cord to a disturbance of circulation resulting from "granulomatous inflammation" with the vascular occlusions in the cord. The case of Serebrjanič¹³ showed extensive metastasis to the brain substance, the cranial nerves, the spinal nerve roots, the root ganglions and the pia-arachnoid of both the brain and the cord. That author believes, however, that only in exceptional cases is the barrier of the dura to invasion of the central nervous system broken down, and he holds that the cord changes seen in the majority of instances are non-

specific and result from direct compression or disturbance of the circulation.

The microscopic studies in the case reported herein support the conception that the granulomatous tissue has a tendency to spread by way of the nerve roots and that the spinal dura mater, even in a somewhat advanced stage of the disease, effectively resists direct penetration. The apparent affinity for the subdural space representing a part of the lymphatic system, in preference to the nervous elements within the dura mater suggests that the nervous tissue per se is damaged only in an incidental way, secondary to the involvement of the lymphatic channels or blood vessels supplying the nervous tissue. Evaluation of the other observations in this case, notably the apparent occlusions of small vessels in the substance of the extradural tumor by masses of cells resembling lymphogranulomatous elements and congestion of the vessels of the cord, is important. In the absence of demonstrable emboli in the vessels elsewhere than in the tumor, one probably is not justified in assuming that in this case the abnormal cells were disseminated through the blood channels, although the vascular occlusions in the epidural structures and vascular congestion in the cord, combined with the evidence of recent degenerative changes in the cord substance at the level of the tumor, indicate the importance of obstruction to the blood circulatory system in connection with the rapidly developing paraplegic symptoms. This is in support of the generally accepted view that circulatory disturbances play an important role in these cases in which the nerve roots are invaded and compressed.

SUMMARY AND CONCLUSIONS

In a case of lymphogranulomatosis maligna the clinical and neuropathologic features have been reported,

Fig. 4—Section of the spinal cord: a, vacuolation of the white matter; b, congestion of the vessels. The ganglion cells seen in this section are in the lateral splanchnic cell column. Hematoxylin-eosin stain. Slightly reduced from a photomicrograph with a magnification of 92 diameters.

with an attempt to correlate, as far as possible, the clinical picture in this and previously reported similar cases with the gross and microscopic pathologic changes. In this case there was a direct extension of lymphogranulomatous tissue from an extradural tumor through

the nerve roots, particularly through their fibrous septums, to the subdural space. There is apparently a greater affinity of this type of abnormal tissue for the structures comprising the lymphatic system, in preference to the structures of the nervous system. The vascular congestion was presumably secondary to compression or occlusion of the vessels in their courses along the nerve roots, and the pronounced degenerative changes in the cord substance have been attributed to this factor.

On the basis of the changes found in this case and those in similar cases reported by other observers, it is concluded that

1 The nerve roots afford a route by which lympho-granulomatous tissue may reach the subdural space, probably through the lymphatic spaces of the roots rather than by the substance of the nerve fibers

2 The spinal dura mater is relatively more resistant to penetration than are the septums of the nerve roots

3 Paraplegic symptoms may result not only from direct cord compression but from obstruction to the circulation of the cord as a result of compression or invasion of the vessels accompanying the nerve roots

THE VALUE OF THE PROTEIN SKIN TESTS IN INFANTILE ECZEMA

LEWIS WEBB HILL, MD
BOSTON

It is well known that infants and young children with eczema very frequently give positive skin tests to various proteins and that normal infants do not. What significance have these tests both in a theoretical discussion of the etiology of the disease and in the practical management of it?

METHODS OF TESTING

Three methods of testing have been employed (1) the cutaneous, (2) the intracutaneous, and (3) the method of passive transfer, or Prausnitz-Kustner phenomenon.

Each has its advantages and disadvantages. The cutaneous test has the advantage of simplicity, and it is not so likely to give false positives as the intracutaneous method. It has been adopted by most allergists for general clinical work. The intracutaneous method is more delicate, but it has the disadvantage of sometimes giving false positives, of occasionally causing general reactions in unusually sensitive subjects and, when a large number of tests with different proteins are to be made, is not practical for general use. It is often of value in special investigative work, however. In the method of passive transfer (Prausnitz-Küstner) a small amount of blood serum from the individual to be tested is injected into the skin of a normal person, and after twenty-four hours the allergen is applied either intracutaneously or cutaneously at the site of the previous inoculation. If the test is positive an urticarial wheal develops in a few moments. This method is accurate and has been of great value in special investigative work, but it is not well adapted for routine use. It may be positive when the ordinary skin test is negative, or it may be negative

when the skin test is positive, but in general the two are parallel. In allergic infants the allergy may be general, in which case both passive transfer and skin tests are positive, or the sensitization may be confined to the skin alone, when the skin test is positive and the passive transfer negative.

For practical purposes the cutaneous test is the most satisfactory to employ in dealing with eczematous infants.

TECHNIC OF TESTING

For infants and young children the back is the best site. The method of scarification is of some importance. It is desired to make a scratch into the skin

Fig 1—Scarifier

without drawing blood and to make each scratch of the same size and depth. Needles or small knives have been usually employed. They are well adapted for use in adults, but it is almost impossible with a struggling infant to make a series of scratches of the same size and depth with a needle or a knife. I have used for some time a circular scarifier $\frac{9}{16}$ inch in diameter,¹ made in the form of a punch with sharpened edges, and have found it very satisfactory (fig 1). Being in the form of a circle, the scratches are always of the same length, and with a little practice it is not difficult to make a series of scratches much more rapidly with this tool than with a needle or a knife, and it is less painful. After the scratches have been made, a small amount of protein powder is applied, and a drop of physiologic solution of sodium chloride is mixed with it. In infants, saline solution is to be preferred to tenth normal solution of sodium hydroxide, on account of the delicacy of the skin.

READING OF THE TESTS

The response to the test varies a great deal in different individuals, according to the particular characteristics of the skin. In some infants there is a certain amount of erythema surrounding every scratch, in

Positive Reactions in Three Hundred Cases of Eczema

Egg	131	Oat	9	Orris powder	5	Codfish	2
Milk	40	Beef	8	Haddock	4	Lamb	2
Wheat	30	Corn	8	Carrot	4	Dog hair	2
Barley	17	Potato	8	Pea	4	Walnut	1
Cat hair	12	Tomato	7	Orange	4	Wool	1
Spinach	11	Silk	6	Chicken	3	Salmon	1

Of 80 infants 6 months of age or under 61% were positive
Of 100 infants 1 year of age or under 63% were positive
Of 52 children 2 years of age or over in whom the eczema had existed since early infancy 77% were positive

others, practically none. Some infants give markedly positive tests with large wheal formation and a surrounding area of erythema (fig 2), others merely show larger or smaller areas of erythema without wheals. The latter type of reaction is more common in infants, and no wheals may be obtained even in markedly sensitive infants (fig 3). In order to interpret the tests

From the Eczema Clinic, Children's Hospital, and the Department of Pediatrics, Harvard Medical School.

¹ Made by Broadbent & Co., Huntington Avenue, Boston.

some practice is necessary, and on account of the varying susceptibility of individual skins there can be no absolute standard by which to judge a positive test. It is in relation to the control and to the other tests that any individual test should be judged, and if a test gives a much larger reaction than the control or the other tests, this is called a positive test.

NATURE OF SKIN TESTS

In a positive skin test with erythema, the essential phenomenon is a dilatation of the small cutaneous vessels. If this dilatation goes on far enough serum exudes through their walls, and wheal formation results. This process has been brought about by the action of the applied allergen either on the sensitized skin cells, which then release a substance capable of causing vessel dilatation, or less likely by direct action on the vessel wall or on the sympathetic nerve endings controlling vessel contraction and dilatation. This phenomenon occurs to a certain extent in normal individuals when the skin is scratched, and Thomas Lewis believes that the mechanical trauma of the scratch releases a histamine-like substance from the skin cells, which then acts on the vessels and causes dilatation. In allergic individuals this process is intensified, owing to the fact that the skin cells have been "sensitized," which is simply another way of saying that some specific change has taken place in them about which practically nothing is known.

Fig. 2—Multiple wheal formation. An unusual type of reaction in infancy.

The process going on in a positive skin test is probably much the same as that which goes on in eczema, and it is likely that the more violent response in eczema is due to repeated and prolonged contact of the cells with the allergen, applied either from within or from without.

INCIDENCE OF POSITIVE TESTS

In 300 eczematous infants and young children, skin tests were positive in 59 per cent, as shown in the accompanying table.

SIGNIFICANCE OF EGG

It is agreed by all allergists that in infancy and childhood egg is by far the most common allergen to which tests are obtained, and that egg white is the particular protein usually responsible. In our series we have most often obtained positive tests to both egg white and egg yolk. Sensitivity to egg is seen especially in infancy,

it diminishes as the child grows older. One hundred infants 1 year old or younger gave fifty-four reactions to egg and 85 per cent of those who were positive to anything were positive to egg. Fifty-two children 2 years old or older gave twenty-three positive reactions to egg (44 per cent), and 57 per cent of those who were positive to anything were positive to egg.

Since positive egg reactions with no other positive reactions are very often obtained in young infants who have never eaten egg, it is obvious that egg is not directly concerned as a cause of the eczema, and for this reason it was formerly thought by many that the tests were not specific, that these infants were not actually sensitized to egg and that the positive tests were due to some peculiarity of egg protein, which was without much significance. Many pediatricians and dermatologists became discouraged with skin testing in eczematous infants and considered it of little value.

Recently, Moro,² and also Woringer,³ have shown, however, that almost all infants who give positive skin tests to egg give also positive passive transfer tests so that it may be said without a doubt that they are sensitized to egg. Since a great many of them are not eating egg it cannot be said that ingestion of the allergen to which they are sensitive is directly causing the eczema. During the early months of life, and as in the majority of these infants nothing could have happened during postnatal life to render them sensitive the sensitivity is either truly hereditary or of placental transmission. It is well known that of all proteins egg white is the most difficult to digest, and Walzer⁴ has shown by use of the passive transfer reaction that unchanged egg white circulates in the blood stream in practically all individuals even after the ingestion of very small amounts. Ratner⁵ has shown that the placenta is permeable to foreign protein. It follows therefore that during pregnancy there may be egg white in the fetal circulation. But only a small proportion of infants are sensitized to egg. This may be due to differences in the amount of egg ingested during pregnancy or more likely to individual peculiarities of the fetus that is heredity.

It is very common in young eczematous infants to obtain positive tests to egg alone and to no other allergens, in older infants and children multiple sensitization is the rule with positive tests to egg and to various other foods and animal epidermals. Of forty-six infants under 6 months of age who gave positive tests to something, forty-two reacted to egg and twenty-four of these reacted to egg alone. Of forty-six infants between 6 and 12 months of age who gave positive tests to something, thirty-nine reacted to egg but only twelve reacted to egg alone. In the first group there were 107 total reactions to various proteins, in the second group there were 151.

Moro has suggested that sensitivity to egg acquired in utero is often the starting point of allergy and that this egg sensitivity does something to the individual which not only renders him sensitive to egg but also makes him susceptible to other sensitivities as he comes into contact with other proteins. Furthermore, it does something to him which renders his skin subject to eczema in spite of the fact that as a young infant he does not come into contact with the allergen to which

² Moro, Ernst. Ekzema infantum und Dermatitis seborrhoides. Berlin, Julius Springer, 1932.
³ Woringer, P. Recherches sur l'allergie ovalbuminique du nourisson. Rev. franc. de pediat. 8: 649, 1932.
⁴ Walzer, Matthew. J. Immunology 11: 249 (April) 1926.
⁵ Ratner, Bret and Greenburgh, J. E. J. Allergy 3: 149 (Jan.) 1932.

he is sensitive (egg) So that eczema can and does exist in the infant without contact with the specific allergen As Moro has said, the soil is prepared by sensitivity to the specific allergen, and then the eczema may be often brought about by various nonspecific causes It is not unlikely that in these egg sensitive infants small amounts of any food protein which are absorbed unsplit into the circulation may bring about eczema, even if these proteins fail to give positive skin tests

Although egg white is by far the most common protein to which infants are sensitive, allergic infants may be nonsensitive to egg and sensitive to other proteins This sensitivity probably arises in the same way as egg sensitivity Although this may occur, it is not common and in eighteen infants who were definitely sensitive to cow's milk, seventeen were sensitive to egg as well, although none of them were eating or had ever eaten an egg

THE SIGNIFICANCE OF MILK SENSITIZATION

Since cow's milk is the sole diet of most young infants when they develop eczema, it deserves consideration as an etiologic factor, either primary or secondary

In 300 infants tested, 45 gave positive reactions to cow's milk These reactions were almost all in young infants In a few cases casein alone gave a reaction, in a few lactalbumin, as a rule both were positive A few of these infants were breast fed and showed violent reactions when given cow's milk for the first time Almost all of them, however, were bottle fed and had been taking cow's milk with no untoward symptoms other than eczema It appears from the figures already given that milk allergy is usually secondary to or at any rate is accompanied by egg allergy There is this peculiarity, however In practically all the infants who are sensitive to milk and to egg, it is possible to cure them by withdrawing cow's milk and using a milk-free diet, whereas in those infants who are sensitive to egg alone, and who are not eating egg, it is not possible to withdraw anything they are eating, and they do not do so well It is true that occasionally an infant who does not give positive skin tests to milk will be cured by removal of milk from the diet, but this is not the rule, and it must be concluded that if milk is causative of the eczema in these cases it is not causative by means of specific sensitization but rather by means of digestive and metabolic factors, such as overfeeding with or poor digestion of any one of the food elements

THEORETICAL VALUE OF THE SKIN TESTS

While it is certainly not true that all eczematous infants are allergic, a great many of them are, probably about two thirds, and the skin tests are indispensable in differentiating and in helping one to understand this group The positive skin tests to egg which are so common in young infants help one not a whit in the practical treatment of the infant, but they do help considerably in a proper understanding of the disease and without allergic study of these infants no progress could be made

The answer to infantile eczema probably lies in a better understanding of egg sensitization and the changes it causes in the immunologic reactions of the body, but there are woful gaps in existing knowledge

PRACTICAL VALUE OF THE SKIN TESTS

The skin tests are of practical value in that they often give indications for treatment, for, no matter

what local treatment is used, good results cannot be obtained in allergic eczema unless the allergic factor is also taken into account

Although many methods of specific and nonspecific desensitization have been tried, they are not at all reliable or satisfactory for general use in eczema, and there is no method at present that can be depended on to render an allergic infant nonallergic Avoidance of the offending food or foods in accordance with the evidence furnished by the skin tests is the method of choice The effectiveness of this procedure varies a great deal, however In young infants with milk sensitivity, avoidance of milk, and the substitution of a milk-free diet is likely to cure or at any rate greatly improve the eczema

Likewise, if there is definite sensitivity to wheat, oats or any food that the child is taking in large amounts,

and there are not many other sensitivities, avoidance of this food is very satisfactory If there is sensitivity to many foods and epidermals, combined with egg sensitivity, however, it is not easy to avoid all of them, and as a matter of fact avoidance may not be productive of good results, for such children sometimes seem to be sensitive to almost any food Avoidance of egg is of course, indicated if the skin test to egg is positive but it is not common to produce a cure by so doing Most infants who are sensitive to food outgrow this sensitivity and even become nonallergic, but in

Fig 3—Erythema with practically no wheal formation The usual type of reaction in a multiply sensitized child

many cases the allergic state persists, and the baby who is sensitive to egg and milk at 6 months is sensitive to horse dander and ragweed or other epidermals at the age of 6 years and may have asthma or hay fever instead of eczema, or perhaps all combined

There can be no truly satisfactory way of dealing with all these allergic manifestations until some effective method becomes available not of treating the symptoms caused by allergy but of attacking the allergic state itself

CONCLUSIONS

- 1 Skin testing in infantile eczema should not be discredited
 - 2 It has been of great value in revealing what little is known of the nature of the disease
 - 3 It often, although not always, points the way to the cure of the patient

Clinical Notes, Suggestions and New Instruments

A CASE OF PSEUDOHERMAPHRODITISM

RITA S FINKLER M.D. NEWARK N. J.

Pseudohermaphroditism has always been a subject of fascination and interest to the urologist, gynecologist and general practitioner. Unusual cases of true hermaphroditism and pseudohermaphroditism have been brought to the attention of the medical profession from time to time. I here present another case, which is of much interest from its clinical, endocrinologic and psychologic aspects.

The patient, brought up as a girl, was first seen by me casually five years ago, while I was attending another member of the family. At that time she was 13½ years old. She was short and stocky, was very timid, and had a deep masculine voice, a square masculine chest without any signs of breast

Fig. 1—Penis shown in place of clitoris. Vagina brought into view by the use of a speculum.

development, and a masculine distribution of hair on the body and extremities. She was not menstruating yet.

I saw the girl again a year later. Her mother called my attention to the fact that her menstrual periods were not as yet established. At that time, while doing some postgraduate work in gynecology at the Mount Sinai Hospital, I became interested in Dr. Frank's work with estrogenic substance.

I suggested such a study to the girl's mother, but as the girl was only 14½ years old, they felt that they could wait a little longer and in the meantime administer endocrine therapy. The girl received intramuscular injections of an estrogenic product and pituitary preparations by mouth all to no avail. She also began to show signs of growth of hair on her face.

In March, 1930, her mother brought her to me in great alarm, since she discovered an appendage at the site of the clitoris. On examination the appendage appeared to be an imperforate penis about 2 inches (5 cm.) long, the crura, glans, prepuce and pigmentation were typical, except that at the site of the urethra

there was a dimple but no canal visible there or anywhere else along the structure. When the patient was asked to void, the urine seemed to come from the vagina. The introitus could admit the tip of the small finger. Rectal examination revealed a small, hard uterine body lying anteriorly, no ovaries could be palpated.

Five weekly specimens of blood were taken and examined for the presence of estrogenic substance by the Frank-Goldberger technique. The fourth specimen showed a trace of the hormone.

Röntgen examination of the sella turcica was negative. The sugar tolerance test was normal. The basal metabolic rate was minus 5 per cent. I suggested a complete study of the urinary tract in order to search for further anomalies.

This study has been carried out at the Newark Beth Israel Hospital by our urologist, Dr. Sidney Keller. The urethral orifice was found to be opening into the right upper vaginal wall. The kidney, ureters and bladder were normal.

Dr. Hugh H. Young¹ of the Urological Institute of Johns Hopkins University has reported a large number of interesting cases of pseudohermaphroditism, and we deemed it advisable to consult him as to further procedures in this particular case.

Because of the great concern of the patient's parents, the girl was taken to Baltimore, where Dr. Young and an attending gynecologist gave her a detailed examination and suggested that it was essential to do an exploratory laparotomy in order to determine whether the gonads were ovaries or testicles. They also suggested a thorough exploration of the suprarenal glands in search of a possible suprarenal tumor.

The patient was operated on at the Newark Beth Israel Hospital under tribromethanol anesthesia by Dr. Sidney Keller, Dr. William Brans and myself.

The surgical procedure consisted of a midline abdominal incision, complete exploration of the pelvic organs, and exploration and palpation of the suprarenal glands. A somewhat underdeveloped uterus and tubes and ovaries were found. A careful search failed to reveal the presence of testicles. The palpation of the suprarenal glands did not reveal the presence of a tumor. The appendix was removed and the abdomen closed.

Because the pelvic organs were those of a female, the hypertrophied clitoris was removed by the usual method for amputation of the penis.

Recovery was uneventful. Stimulating doses of x-rays were given to the regions of the pituitary gland and the ovaries, under the direction of Dr. Milton Freedman. However, following each treatment the patient became quite ill with headaches and nausea, so that roentgen therapy had to be discontinued.

She was given a two months rest period and was then placed on endocrine therapy, which was checked by the hormone study of the blood and urine.

Blood and urine hormone determinations were made after the administration of anterior pituitary-like and estrogenic hormones. Blood studies never showed more than a trace of estrogenic hormone, but the urine showed a rapid elimination of both hormones.

During periods of rest, when no hormone treatment was administered, the content of estrogenic factor in the urine was 4½ rat units per liter, estimated by the Kurzrok method; the blood began to show a more constant presence of estrogenic hormone (Frank-Goldberger technique).

After treatment over a period of one year there was some improvement in the physical and psychologic make-up of the patient. The voice began to lose its masculine tone, she became less timid and silent, and her body rounded out a little. However, she did not begin to menstruate. There was no noticeable breast development, and the growth of hair on her face continued to be her great concern. She had to shave twice a week. I felt that a growth hormone was necessary to supplement the sex hormones. An aqueous preparation of the anterior lobe of the pituitary prepared by the van Dyke and Wallen-Lawrence method (University of Chicago) was obtained from the Wilson Laboratories.

From the service of Dr. Edwin Steiner, Department of Gynecology, Newark Beth Israel Hospital.

Read before the annual meeting of the Alumnae Association of the Women's Medical College, Philadelphia, June 6, 1933.

¹ Young, H. H. *Bull. Johns Hopkins Hosp.* 25: 165 (June) 1924.

I used this preparation in conjunction with filtered pregnancy urine. Certain German scientists assert that pregnancy urine from the fourth to the seventh month contains not only estrogenic and anterior pituitary-like hormones but also a growth hormone.

Five cubic centimeters of filtered pregnancy urine and 1 cc of the growth-inducing preparation were given intramuscularly every other day. This was supplemented by diathermy to vascularize the pelvis. Small doses of desiccated thyroid were given at intervals. March 16, 1933, after eight or ten weeks, when the patient was 18½ years of age, she had her first menstrual period, which lasted seven days. Besides the establishment of the period, the growth of hair on her face began to diminish. She uses a hair remover for her face only once every two weeks. Her features and body are rounding out, the breasts are beginning to develop, and the voice is almost entirely feminine in character.

The girl is bright and alert and looks very happy. Until about six months ago she spoke little, was very self-conscious and looked like a hunted animal.

After her first menstrual period, she returned to me for further treatment of filtered urine injections and pelvic diathermy. Her second period occurred after six weeks of this treatment. The growth hormone was not used, since a fresh supply was not available at that time. So far the girl has had three more periods, from four to five weeks apart, lasting four or five days.

Fig 2—Removed appendage shows all the characteristics of a penis except for the absence of a urethra.

COMMENT

Many striking and varied cases of true hermaphroditism and pseudohermaphroditism have been reported in medical literature. The most interesting case is that reported by Dr James C Masson² in 1925 and by Dr Burden³ in 1924 in which an apparently normal man of 30 developed periodic attacks of hematuria, lasting from three to four days and appearing at intervals of from four to five weeks.

At the age of 40 this man was operated on for an abdominal tumor and found to have a didelphic uterus, both horns being distended with menstrual blood, the cervix leading into a small pouch, which opened into the urethra. Normal ovaries containing cysts were found in the broad ligaments and testicular tissue was found on each side containing spermatozoa in the ducts.

In true hermaphroditism and pseudohermaphroditism the change in secondary sex characters usually appears at the time of puberty, when the whole chain of endocrine glands receives an impetus to new and vigorous activities. The change in the growing child is noticed by the parents and any abnormalities become evident at that time.

It is usually at this period that the physician is consulted and the responsibility of determining the true sex of the individual often rests on the consultant.

Sometimes it is best to bring up the individual as a female in spite of the presence of male gonads and vice versa. Environmental inclinations and social standing must be considered. The

point is well illustrated by the case reported by Dr Walton Martin,⁴ in which a deaf and dumb imbecile brought up as a girl was later proved to have undescended testicles in the inguinal regions and a penis bound down by adhesions, the urethra opened into a vagina. It was deemed best to remove the testicles, amputate the penis, and leave the patient as a girl.

Recent advances in the hormone study of the blood and urine have proved to be of considerable help in the diagnosis and treatment of the patient whose case is presented on these pages.

Later studies showed the gradual increase in the ovarian activity and also the presence of a possible low renal threshold, the latter conclusion is drawn from the fact that the ovarian and pituitary-like preparations administered intramuscularly were rapidly eliminated in the urine.

SUMMARY

The value of the results of the blood and urine hormone studies is as follows:

- 1 Direct aid to diagnosis and treatment
- 2 Indication of the presence of the ovaries and the amount of ovarian activity
- 3 Determination of the renal threshold by the rate of elimination of hormones

99 Lyons Avenue

SUPRARENAL VIRILISM IN A WOMAN

(TUMOR OF AN EXTRARENAL SUPRARENAL REST)

ANATOLE KOLODNY, M.D., Ph.D., SIOUX CITY, IOWA

Virchow's statement "propter ovarium solum mulier est quod est" (woman is what she is solely because of the ovary) is refuted by present-day knowledge of the functional relationship of the various ductless glands to the sexual life of woman. Since Apert in 1910 called attention to the influence of a hyperplasia of the suprarenals on the female sex characteristics, numerous contributions to this question have appeared in the literature and abundant clinical material demonstrating this fact has been placed on record. Anatomic studies have appeared explaining this functional relationship since the anlage of the suprarenal cortex appears to be close to the sex gland anlage, both primordia partly coalesce and hence their functional interdependence in later life.

For this clinical relationship Gallais coined the descriptive term "syndrome genitosurrenale." The literature abounds with reports of cases demonstrating this syndrome, in which tumors of the suprarenals cause sex abnormalities. However, it has never been sufficiently established that similar sex disturbances might appear in the wake of a tumor arising from an extrarenal suprarenal rest. The only literature dealing with sexual abnormalities appearing as a consequence of tumors of extrarenal suprarenal rests refers to tumors of the ovary, the "ovarian hypernephromas," which probably are related to the arrhenoblastomas.

The extrarenal suprarenal rests first described by Marchand, the so-called Marchandsche Nebennieren, are to be found distally to the lower pole of the kidney, between the kidney and the genital glands. In the female, these rests are found in the ligamentum latum and in the male in the neighborhood of the testis and spermatic cord. Later Schmorl described suprarenal rests also in the region of the solar plexus. The literature does not contain any evidence that the latter suprarenal rests may give rise to tumors leading to sexual disturbances.

I aim to place on record an unusual case of the "syndrome genitosurrenale," which accompanied a cortical suprarenal tumor arising in an extrarenal suprarenal rest in the region of the solar plexus.

A white woman aged 37, the mother of a grown son, felt a lump in the left epigastrium in the fall of 1932. The lump was growing fast and soon she complained of digestive diffi-

² Masson J C True Hermaphroditism Am J Obst & Gynec 81:86 (Jan) 1925
³ Burden A G J Urol 12 153 (Aug) 1924

⁴ Martin Walton Pseudohermaphroditismus Masculinus S Clin North America 9 535 544 (June) 1929

culties. About eight months before she had felt the lump, menstruation had stopped entirely. Two months after the cessation of menstruation she was growing a mustache and hair on the chin. The thorax as well as the inner upper arm and below the navel were covered with hair. During the last six months she felt a fullness in her head and thumping in her ears and head when she was lying in bed. Despite a sick feeling in the stomach and an inability to consume proper amounts of food, she gained 8 pounds (3.6 Kg.) in six months.

Fig. 1—Section of the tumor which penetrated through the muscular layer of the stomach and approached the gastric mucosa.

She was rather obese, her voice was coarse and ugly and the skin was red and rough. Instead of the female horizontal pubescence there was a definite male vertical. The face, chin, upper lip, forearms, arms, thighs and legs were covered with hair. The scalp was dry. The clitoris was at least twice the normal size. The labia were covered with hair and the breasts were quite small. The blood pressure in millimeters of mercury was 185 systolic and 105 diastolic. The hemoglobin was 35 per cent (Dare).

An examination of the abdomen showed a tumor the size of a child's head in the epigastrium to the left of the middle line. The tumor felt smooth, soft, elastic and definitely adherent to the anterior abdominal wall. Palpation and moving of the tumor caused eructations of gas. The gastric secretion following the ingestion of a test meal showed a complete absence of free hydrochloric acid and a greatly reduced combined acidity. There was in the gastric contents definite evidence of blood. A fluoroscopic examination showed a large filling defect along the greater curvature of the stomach. The transverse colon was fixed to the tumor at its inferior border.

Because of the masculinization of the patient, suprarenal tumor was suspected. An examination of the kidneys showed them to be normal in size, location and function. With these observations I was rather at a loss as to the exact diagnosis, although it was evident that surgery was indicated and justified. The patient was operated on, December 20. Several blood transfusions preceded the operation. The tumor was found to be the size of a child's head, adherent to the anterior abdominal wall. The transverse colon was tightly stretched over the inferior and posterior aspect of the tumor. A careful dissection of the transverse colon showed that the tumor approached it through the mesocolon. One could definitely distinguish the two sheets of the peritoneum forming the mesocolon, pushed apart by the tumor that was wedging in from behind and approaching the transverse colon. Following the dissection of the transverse colon the tumor was free throughout, with the exception of its superior aspect where it approached the stomach. Here there was a very intimate connection between the tumor and the stomach. The tumor invaded the stomach, destroyed a large portion of the greater curvature and grew into the stomach cavity, causing a narrowing and obstruction of it. Since only a resection of the stomach would make possible a complete removal of the tumor, gastric

resection according to the first method of Billroth was done, and the tumor together with 15 cm. of the stomach removed.

The patient made a good postoperative recovery. She left the hospital on the fourteenth day after operation. The refeminization of the patient was striking. Six weeks after the operation she menstruated for the first time in the past ten months. Her libido, which had been absent for the past year and a half, commenced to return. Her voice became more feminine and the growth of hair on the face was disappearing. She kept improving rapidly until six months after the operation, when a pain developed in the right side of the chest. A roentgen examination revealed pulmonary metastases and the patient died seven months after the operation. Up to the time of her death her appearance kept getting more feminine and menstruation remained normal.

The pathologic specimen showed the distal half of the stomach invaded by a tumor weighing 1,250 Gm. The tumor was round, soft, fragile, grayish yellow and very vascular, containing many hemorrhagic areas. Numerous yellow white nodules were seen dispersed throughout the soft hemorrhagic mass. The capsule of the tumor was intact except at the point of invasion of the stomach.

The histologic examination showed wide strands of large clear cells anastomosing freely with one another. Abundant droplets of lipoids were demonstrated in the cells, while no sign of degeneration was seen in them. The Lubarsch glycogen reaction was positive. Widely gaping thin-walled blood vessels coursed between the wide strands of polygonal cells. In other areas a tubular perivascular arrangement predominated. The tubules were surrounded by a vascular stroma. Large polyhedral cells with round or oval nuclei formed these tubules. The cytoplasm of the cells was vacuolated or foamy from the presence of fat or doubly refractive material. In general the appearance of the growth recalled the suprarenal cortex, and the general arrangement of the cells, connective tissue and vessels suggested the zona fasciculata.

Fig. 2—Section showing the foamy appearance of the cells.

The situation of this tumor as found at operation between the leaves of the mesocolon suggests the origin of the tumor from a suprarenal rest in the region of the solar plexus. Such a situation of an extrarenal suprarenal rest is unusual, since most suprarenal rests are found along the internal spermatic vein or in the neighborhood of the pelvic organs. This is the first report of a case of suprarenal hirsutism developing as a result of a cortical suprarenal tumor arising in a suprarenal rest in the neighborhood of the solar plexus.

PRIMARY CARCINOMA OF THE LUNG IN A TWENTY
THREE YEAR OLD MAN

L A CROWELL JR MD, LINCOLTON, N C

Since primary carcinoma of the lung is rare in the twenties I thought it would be of interest to present this case

H D R, a man, aged 23, a textile foreman, admitted to the Lincoln Hospital, July 14, 1933, suffered chiefly from cough, dyspnea, pain in the right side of the chest and weakness. The illness began May 26, seven weeks before admission, with the sudden development of a cough with expectoration of brown sputum. The family stated that he had seemed more irritable and out of sorts since February 1933 and had lost weight during that time, although he had had no definite localizing symptoms. The cough got steadily worse until two weeks before admission, when the patient, while at work, suddenly had a severe lancinating pain in the middle of the right chest made worse by inspiration and by the beating of the heart. He immediately sought medical aid, went to bed and received symptomatic treatment.

During the succeeding ten days the cough disappeared, the expectoration decreased and the pain abated. A tuberculosis specialist at this time recommended sanatorium observation.

July 11 the patient suddenly became more dyspneic, the pain dull in character, became more intense, cyanosis increased, weakness increased, appetite disappeared, the digestion became poorer, and the heart beats became more frequent.

Previous to the present illness the patient had always been in rugged good health. He had worked in the spinning room of a cotton mill for ten years. The patient had influenza one year before but had never had pneumonia. There was no history of lung disease in his or in his wife's family.

On admission the patient's temperature was 100.4 F, the pulse was 100 and respiration was 30 and labored. The blood pressure was 125 systolic and 85 diastolic. There was a moderate amount of pyorrhea, the tongue was coated a brownish white, the tonsils were normal and the thyroid gland was slightly palpable.

The superficial veins in the neck and in the epigastric and hypochondriac regions were moderately distended. The patient was laboring for breath and made a slight expiratory grunt. The skin and mucous membranes were slightly cyanotic. At this time there was a noticeable puffiness in the right supraclavicular space and a slight fullness about the head neck and the upper half of the chest. The patient was unable to sit or stand for more than thirty seconds without going into a violent paroxysm of coughing, followed by severe dyspnea and cyanosis. The heart rate greatly increased at each such attempt. No adventitious heart sounds were heard. The cardiac apex was displaced 1 inch to the left.

Examination of the right lung revealed diminished expansion, a flat note below the second rib anteriorly and dullness from the apex to the second rib. Breath sounds over the entire side were greatly diminished. Whispered voice sounds were increased especially over the upper half. Tactile vocal fremitus was diminished over the entire side. Three or four punctate scars from unsuccessful attempts made to aspirate the right pleural space seven and ten days before admission were found about the inferior angle of the right scapula.

Examination of the left lung revealed no abnormalities except slight prolongation of expiration and slight exaggeration of breath sounds.

The epigastric and hypochondriac veins were distended. The right lobe of the liver was enlarged to four fingerbreadths below the costal margin and the left lobe was two fingerbreadths below. All reflexes were negative.

The blood count revealed 12,000 leukocytes of which 78 per cent were polymorphonuclears, hemoglobin was 75 per cent, the urine was normal and the blood Wassermann reaction was negative. A single roentgenogram of the chest revealed the right lung field completely blotted out by an opaque density except for two or three irregular small areas of greater transmission of the rays in the upper lobe area. An oblique roentgenogram of the chest, made nine days after admission, showed a fluid level at the level of the clavicle. (Special precautions were

taken during the aspiration, by the use of a rubber tube between the syringe and the needle, to prevent the suction of air into the pleural space during aspiration.)

On the day of admission, 650 cc of port wine colored fluid, having a moderate tendency toward coagulation, was removed from the right pleural space. This fluid had a specific gravity of 1.0145. A differential cell count showed 94 per cent lymphocytes and 6 per cent polymorphonuclear leukocytes. The red cells were abundant. No other cells were found. Albumin was present, 10.5 per cent wet and 2 per cent dry. No tubercle bacilli were found on direct smear or on the inoculation of 10 cc of fluid sediment into a guinea-pig. No aerobic growth was obtained. The patient experienced considerable relief after that aspiration.

Two days after admission an attempt to aspirate the chest was unsuccessful even at the site of the previous aspiration. On the fourth day following admission the patient began to show distinct signs of edema about the right shoulder and neck. This, at first, was nonpitting in character.

Six days after admission 800 cc of port wine colored fluid was aspirated from the right pleural space. This contained many red cells. At the end of this operation the patient went into a paroxysm of coughing and became dyspneic and somewhat cyanotic but soon recovered his breath and color. During the succeeding week edema and cyanosis increased rapidly, and a peculiar flatness appeared in the tone of the patient's voice. Cough increased and became productive of from half an ounce to an ounce of brown, rusty and frothy sputum. The patient gradually became more restless and sleepless. The aspiration of 800 cc of fluid seemed to relieve the dyspnea and reduce the edema slightly but not as much as the first one. On the eighth day following admission 500 cc of the same type of fluid was withdrawn, which showed a marked tendency toward coagulation. By this time the edema of the neck, shoulder and head had become quite marked and had become pitting in character.

Ten days after admission, 250 cc of fluid was withdrawn with difficulty. On the thirteenth day 150 cc was withdrawn with greater difficulty, and from then on the needle failed to find the pleural space but seemed to strike tough tissue just beyond the depth at which it had been customary to obtain fluid. By this time the patient's cough had increased until it was almost continuous, in spite of liberal doses of cough medicine. While the patient was coughing there would appear over the head, neck and right side of the chest a diffuse blush. Signs of oxygen want became increasingly evident.

About August 1 the patient was put on morphine, with little apparent effect. During the third week after admission the leukocyte count was the same, but the polymorphonuclear count had moved from 78 to 85 per cent. Three days before death the patient became slightly delirious and began having hallucinations and talking at random, with occasional periods of lucidity. On the day before death the white blood count was 15,000 with 90 per cent polymorphonuclears, and examination of the urine was negative.

The edema continued and the patient's head, neck and shoulders became enormous. Toward the last he was unable to turn his head, the trachea seemed almost entirely occluded and respiration was carried on with great difficulty and effort.

Edema of the left lung appeared two days before death. There was surprisingly little displacement of the mediastinum at this time—only about 1 inch.

The temperature during his stay in the hospital ranged from 97 to 102.6 F, tending to be higher as the patient approached death, the pulse ranged between 78 and 150, tending to get higher as the patient neared death, the respiration rate ranged from 9 to 50, getting higher as the end approached, except that the rate gradually went down during the last eighteen hours.

The autopsy revealed that the right lung was a solid mass of tough but friable tissue. The upper two lobes and the upper half of the lower lobe were fairly hard and dense, but the lower half of the lower lobe was necrotic and semiliquefied. The pleural space on the right was almost completely obliterated, and the upper and middle lobes of the right lung were pressed hard into the superior mediastinum, especially against the superior vena cava, trachea and right pulmonary veins. The lumen of the superior vena cava was practically occluded and

the trachea was bowed to the left and its lumen was reduced 75 per cent at the point of greatest pressure

Serous fluid was found in the pericardium, the left pleural space and the peritoneal cavity. No enlarged lymphatic glands or metastases were found anywhere. The liver, however, was enlarged from chronic passive congestion.

The cut section of the diseased lung was grayish white and solid and showed small white nodules in the pleura and areas of necrosis and softening in the deeper tissue.

Paraffin sections showed none of the original lung structure but showed a diffuse infiltrating neoplastic growth with necrosis and hemorrhage and excessive connective tissue. The cell was spindle shaped and columnar and arranged in hollow alveolar formation in the softer tissue.

The diagnosis was carcinoma, derived from the epithelium lining the bronchus.

A SIMPLE METHOD FOR RETAINING THYROID DRESSINGS

MANDEL WEINSTEIN, M.D., LONG ISLAND CITY, N. Y.

The low position of a thyroid incision has always presented a problem in postoperative bandaging. This region is too low for a properly applied neck bandage and too high for a chest dressing. The usual methods for retaining sterile gauze dressings following thyroidectomy include fixation by adhesive plaster

Supporting bandage for thyroid incision. A, pattern for cutting bandage; B, finished bandage; C, D, application of bandage front and back.

or gauze bandaging. Retention by adhesive strips is uncomfortable, traumatizes sensitive skin and prohibits movements of the neck on the trunk. Gauze bandaging, on the other hand, is bulky, limits motion of the neck and causes pain and discomfort, owing to pressure and tension over the wound.

The supporting bandage that I have been using is made as follows: A flannel bandage 6 inches in width is cut to a length of approximately 36 inches. The width is reduced by a 1 inch strip, cut from each end and almost meeting at the center (A in the illustration), allowing the 1 inch strip to remain attached by approximately 2 inches. The wider flannel band, 5 inches in width, is used to enclose the neck, while the 1 inch band spans the chest, passes under each axilla and is tied in the back. One roughly measures the length of the wider band necessary to cover the sterile bandages and encircle the neck, and this is shortened accordingly (B). However, the narrower band of flannel must of necessity remain long to be tied behind

the patient (C, D). Safety pins or narrow adhesive strips are used to fasten the neck band, while a simple bow or knot finishes off the chest strip of flannel. This flannel bandage is removed with ease and may be used for several days without being replaced. In addition, patients enjoy the warmth from the flannel bandage and the complete enclosure of the neck.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS COMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES TO WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

ORTAL-SODIUM — Sodium *n*-hexylethyl barbiturate.—

Sodium *n*-hexylethyl malonylurea— $\text{NaCH}_2\text{CH}(\text{CH}_2)_4\text{CH}_2\text{C}(\text{CH}_3)(\text{CH}_2)_4\text{C}(\text{NHCO})\text{NCO}$. The monosodium salt of

n-hexylethyl barbituric acid. Ortol-sodium differs from soluble barbituric acid, U. S. P. (sodium diethylbarbiturate), in that one of the ethyl groups of the latter is replaced in the former by a *n*-hexyl group.

Actions and Uses.—The actions and uses of ortol sodium are essentially similar to those of barbituric acid, but ortol sodium is more active than barbituric acid and it is used in correspondingly smaller doses.

Dosage. From 0.2 to 0.4 Gm. (3 to 6 grains) followed by a glass of water. It is rarely necessary to give more than 1 Gm. (15 grains) in twenty-four hours. When oral administration is contraindicated, ortol sodium may be administered rectally.

Manufactured by Parke Davis & Company, Detroit, U. S. patent 1,624,546 (April 12, 1927, expires 1944). U. S. trade mark 302,616.

Capsules Ortol Sodium 3 grains (0.2 Gm.)

Caution. Aqueous solutions of ortol sodium are not stable but decompose on standing; on boiling a precipitation occurs with evolution of ammonia.

Ortol sodium is an odorless white or slightly yellowish powder with a bitter taste, very soluble in water, soluble in alcohol, practically insoluble in ether and benzene. An aqueous solution of ortol sodium has an alkaline reaction to litmus.

Dissolve about 0.5 Gm. of ortol sodium in 100 cc. of water and an excess of diluted hydrochloric acid, collect the resultant hexylethyl barbituric acid on a filter, wash and dry at 90° C. It melts at 122–123° C. Incinerate about 1 Gm. of ortol sodium; the residue responds to tests for sodium carbonate. Boil about 0.5 Gm. of ortol sodium with 5 cc. of a 25 per cent sodium hydroxide solution; it is decomposed with evolution of ammonia. Dissolve about 0.3 Gm. of ortol sodium in 10 cc. of water and divide into two portions; to one portion add 1 cc. of a mercuric chloride solution; a white precipitate results, soluble in an excess of ammonia; to the other portion add 5 cc. of silver nitrate solution; a white precipitate results, soluble in an excess of ammonia.

Dissolve about 0.5 Gm. of ortol sodium in 50 cc. of water and add 5 cc. of diluted nitric acid and filter through paper. Separate portions of 10 cc. each of the filtrate yield no greater opalescence on the addition of 1 cc. of silver nitrate solution than that produced by 0.25 cc. of tenth normal hydrochloric acid in 50 cc. of water (chloride) nor turbidity on the addition of 1 cc. of barium nitrate solution (sulphate). To about 0.2 Gm. of ortol sodium in 25 cc. of water add 1 cc. of diluted hydrochloric acid; filter through paper; the filtrate yields no coloration or precipitation on saturation with hydrogen sulphide (salts of heavy metals). Add about 0.1 Gm. of ortol sodium to 1 cc. of sulphuric acid; the solution is colorless (readily carbonizable substances).

Transfer about 1 Gm. of ortol sodium accurately weighed to a glass stoppered cylinder, add 50 cc. of anhydrous ether, stopper and shake for ten minutes; decant the supernatant liquid through filter paper and repeat twice using 25 cc. and 15 cc. portions respectively of ether, utilizing the same filter; evaporate the combined filtrates to dryness in a tared beaker and dry to constant weight at 90° C. The residue does not exceed 0.5 per cent (uncombined hexylethyl barbituric acid).

Dry about 1 Gm. of ortol sodium accurately weighed to constant weight at 100° C. The loss does not exceed 2.5 per cent. Transfer about 0.5 Gm. of ortol sodium accurately weighed to a suitable Squibb separatory funnel, add 50 cc. of water followed by 10 cc. of diluted hydrochloric acid, extract with eight successive portions of ether in 25 cc. each; evaporate the combined ethereal extractions to dryness in a stream of warm air and dry to constant weight at 90° C. The amount of hexylethyl barbituric acid corresponds to not less than 90.8 per cent nor more than 91.6 per cent calculated to the dried substance. Transfer the acidulated aqueous portion from the foregoing immiscible solvent extraction to a tared platinum dish and evaporate to dryness on a steam bath; to the residue obtained add 5 cc. of sulphuric acid; heat cautiously until the excess of sulphuric acid has been volatilized; repeat twice using portions of 1 cc. each of sulphuric acid each time; add about 0.5 Gm. of ammonium carbonate; ignite to constant weight and weigh as sodium sulphate; the percentage of sodium corresponds to not less than 8.5 per cent nor more than 9 per cent when calculated to the dried substance.

DIGALEN-ROCHE (CLOETTA) (See New and Non-official Remedies, 1934, p 158)

The following dosage form has been accepted
Tablets Digalen Roche 1 Cat Unit

DEXTROSE (See New and Nonofficial Remedies, 1934, p 270)

The following dosage forms have been accepted

Ampoule Solution Dextrose 25 Gm in 50 cc Each ampule contains dextrose U S P 25 Gm in distilled water to make 50 cc buffered with sodium citrate 0.25 per cent

Prepared by John Wyeth & Brother Inc Philadelphia

Ampoule Solution Dextrose 50 Gm in 100 cc Each ampule contains dextrose U S P 50 Gm in distilled water to make 100 cc buffered with sodium citrate 0.25 per cent

Prepared by John Wyeth & Brother Inc Philadelphia

PROCAINE BORATE-SEARLE (See New and Non-official Remedies, 1934, p 59)

The following dosage form has been accepted

Tablets Procaine Borate without Epinephrine Each tablet contains procaine borate Searle 0.05 Gm (34 grain)

SHEFIELD B ACIDOPHILUS MILK—A whole milk cultured with *Bacillus acidophilus*. It contains not less than 250 million viable organisms per cubic centimeter at the time of sale

Actions and Uses—See general article Lactic Acid-Producing Organisms and Preparations, New and Nonofficial Remedies, 1934, p 250

Dosage—For adults 1000 cc per day, increased or decreased to meet individual requirements. When employed in infant feeding it may be diluted with boiled water. Sheffield B acidophilus milk must be kept in a cool place and should be used prior to the expiration date stamped on the label

Manufactured by the Cheplin Biological Laboratories Inc Syracuse N Y (Sheffield Farms Co Inc New York N Y distributor) No U S patent or trademark

Fresh whole cow's milk with a butter fat content of not less than 3 per cent is sterilized at 100 C for two hours. After cooling to 37 C the milk is inoculated with a twenty hour seed culture of pure strains of *Bacillus acidophilus*. After inoculation the milk is kept at 37 C for from twenty to twenty-four hours until an acidity is reached such that 10 cc will require for neutralization 8 cc of tenth normal sodium hydroxide solution phenolphthalein being used as indicator. The product is then cooled agitated until homogeneous and transferred to one-half pint and quart bottles. The strains of *Bacillus acidophilus* used are isolated by Cheplin. To insure a high degree of activity and colonization within the human alimentary tract the organism is freshly isolated from human intestinal contents as frequently as is found necessary through actual feeding experiments

PRELIMINARY REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
PRELIMINARY REPORT PAUL NICHOLAS LEECH Secretary

CYSTEINE HYDROCHLORIDE

Substances containing a negatively charged sulphur atom have been used in the treatment of cutaneous ulcers. The work of Reimann¹ with thiocresol was a forerunner. Thiocresol possessed certain disadvantages, such as undue irritation and unpleasant odor. Kendall,² after isolating crystalline glutathione suggested that it might have essentially the same effect as thiocresol owing to the common presence of the S-H or sulphhydryl radical. The results obtained by Brunsting and Simonsen³ showed glutathione definitely effective but, because of expense cysteine was substituted by these authors in subsequent investigations.

Intractable persistent, unhealthy ulcers of various origin are reported as responding with a fair measure of success when due to trauma, burns and circulatory defects but practically no response is found in the specific ulcerations (i.e. scrofulous sinuses, Bazin ulcers, nodulo ulcerative syphilids, pustular psoriasis, lichen simplex and lichen planus).

¹ Reimann S P. Use and Reasons for the Use of Thiocresol to Stimulate Wound Healing. J A M A 94 1369 (May 3) 1930

² Kendall E C, McKenzie B F and Mason H L. A Study of Glutathione. I. Its Preparation in Crystalline Form and Its Identification. J Biol Chem 54 657 (Nov.) 1929

³ Brunsting L A and Simonsen D G. Cutaneous Ulcers Treated by the Sulphydryl Containing Amino-Acid Cysteine. J A M A 101 10 (Dec 16) 1931

It is worthy of comment that an amino-acid such as cysteine, whose bimolecular oxidation product, cystine, is one of those qualitatively necessary in the protein fraction of the diet, should exhibit such stimulating properties on damaged tissue, but the action may be explained on reasonably sound theoretical grounds, which, however, are entirely speculative. The formula for glutathione is

Reduced glutathione

Oxidized glutathione

It is the opinion of F Gowland Hopkins that glutathione plays a very significant if not fundamental role in oxidative metabolism within the cell. He has demonstrated⁴ a relatively constant concentration of about 0.01 per cent in healthy tissues. It is apparent that the glutamic acid is, for all practical purposes, inert and that the reaction centers in the SH group and the cysteine \rightleftharpoons cystine conjugation. Whether cysteine and cystine can or do act as does glutathione is not so important, since an additional conjugation with glutamic acid could conceivably take place within or adjacent to the cell, thus producing the active compound.

The possibility immediately suggests itself that the stimulating properties of cysteine, applied locally, lie in the production of a greater intracellular metabolism brought about either by the cysteine itself or by glutathione formed at the site of application. The simple chain of events would be (as is well demonstrated for cell growth)

Increased metabolism \rightarrow karyokinesis \rightarrow multiplication \rightarrow tissue repair

That this may actually be the mechanism is suggested more strongly by the fact that the lesions wherein good results were obtained consisted in ischemic unhealthy, devitalized tissues *not* the seat of specific disease, while little effect was found in the specific ulcerations.

Adlersberg and Perutz⁵ have effected more rapid healing of indolent leg ulcers by the local application of insulin, a compound that is known to contain suboxidized sulphur. While Hammett⁶ was unable to verify their work with oxidized glutathione, both he and Voegtlin and Chalkley⁷ (the latter working with *Amoeba proteus*) have demonstrated increased nuclear and cytoplasmic division in the presence of glutathione in 1:100,000 dilution. The effect is reported to be much more pronounced in the case of more mature (larger) amoebas and practically absent in the smallest specimens. Results of that sort would apparently indicate that the sulphhydryl group might not have a stimulating effect on malignant tissue, since such tissue is relatively immature. However, in the light of other studies, by Voegtlin and Thompson⁸ and by Lecloux⁹ it appears certain that cysteine or a sulphhydryl (-SH) compound should not be applied to malignant or precancerous ulcerations. These authors have shown that active tumor tissue contains as much glutathione as liver substance which is among the richest of all organs in that compound. In the same paper on *Amoeba proteus*, Chalkley and Voegtlin^{7a} record the proliferative effect on nuclei to be much more pronounced than that on cytoplasm, a fact that further militates against the use of

sulphydryl-containing substances on malignant tissue, which always contains a greater percentage of mitotic or potentially mitotic nuclear material, and relatively less cytoplasm, than its normal counterpart

It should be remembered that, however promising and unique (in modus operandi) the method may be, it should until the development of further confirmatory evidence, be considered as a possibly helpful adjunct to the older, established treatments for refractory cutaneous ulcers of nonspecific origin

It is well to emphasize that cysteine should not be used in the treatment of any cutaneous ulceration in which possibly malignant or premalignant conditions cannot be excluded

The Council voted to postpone consideration of cysteine hydrochloride until further evidence becomes available. If sufficient data warrant acceptance in the future, the A. M. A. Chemical Laboratory will be asked to investigate the product with a view to elaborating standards

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEITCH, Secretary

I-X BARIUM MEAL OMITTED FROM N N R AND I-X BARIUM UNFLAVORED NOT ACCEPTABLE FOR N N R

I-X Barium Meal (Dick & Ryan Co.) was accepted by the Council in 1929 as a barium sulphate preparation for use in roentgen examination of the gastro-intestinal tract. It is described as a mixture of barium sulphate, U. S. P. 85 per cent, native aluminum silicate, 10 per cent, malted milk (malt extract powder), 5 per cent, and a trace of saccharin. The period for which the product was accepted expiring at the close of 1932, the firm was asked for evidence for its eligibility for continued inclusion in New and Nonofficial Remedies.

A short time previously the firm had presented for the Council's consideration an additional barium sulphate preparation for roentgen examination of the gastro-intestinal tract. I-X Barium Unflavored, stated to consist of barium sulphate U. S. P. 92½ per cent and "the same suspension agent used in I-X Barium Meal in the amount of 7½%.

The firm submitted an advertising circular dealing with both the accepted and the newly submitted products. The Council found a number of objections to this circular: some generalized claims of superlative merit and the claim that with the use of the products "Constipation is Minimized and Better Radiographs Result." The firm was asked to tone down the superlative statements and to submit evidence to substantiate the two claims just mentioned. The firm was also informed that, in accordance with the Council's requirements for similar products, the word "sulphate" should appear in the names of the two products and, further, that a quantitative statement of the composition should appear in advertising and on the labels of the respective products. Ample time was accorded the firm to use up existing stock of the advertising and of the lithographed cans in which the products are marketed.

The firm was further informed that the product previously accepted as "I-X Barium Meal" would be reaccepted as "I-X Barium Sulphate Meal" and the product submitted as "I-X Barium Unflavored" would be accepted as "I-X Barium Sulphate Unflavored" when the advertising was revised to meet the objections stated and when agreement was given to make the stipulated changes of name on the trade packages and in the advertising.

The firm replied that it contemplated making a radical change in "I-X Barium Meal" "within two months," as a result of which new advertising and containers would be required, at which time the requests of the Council could be met. After the expiration of the stipulated time, the firm was asked whether these changes were being made. The firm has failed to give a satisfactory reply indicating its willingness to comply with the Council's rules. The Council was therefore obliged to omit "I-X Barium Meal" from New and Nonofficial Remedies and to declare "I-X Barium Unflavored" unacceptable for New and Nonofficial Remedies, without prejudice to future consideration of either or both products.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
RAYMOND HERTWIG, Secretary

ACCEPTANCE WITHDRAWN

BUTTER CREAM BREAD

The Anchor Bread Company, Sacramento, Calif., submitted to the Committee on Foods a white bread made by the sponge dough method, called Butter Cream Bread, prepared from flour, water, cream, sugar, salt, butter, yeast and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Analysis (submitted by manufacturer) —	per cent
Moisture (entire loaf)	33.3
Ash	1.0
Fat	3.7
Protein (N x 6.25)	6.4
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	55.3

Discussion of Name—"Butter cream bread" has not been defined by the United States Department of Agriculture. The baking trade has no recognized trade opinion on the composition of a "butter cream bread." Although the bread contains considerable butter and cream and somewhat more milk fat than "milk bread" their quantity is not considered sufficient to warrant the emphasis of milk fat content given by the name. The continued acceptance of this bread will serve as a precedent for the adoption of similar names for other bread brands, thereby extending any misinformative connotations of the significance of the term "butter cream" and will convey the impression that this type of bread is recognized by the United States Department of Agriculture and the baking trade, which is not the case. A food name should not unduly emphasize the importance of any ingredient, thereby misleading the public as to the composition of the product or its nutritional values.

The manufacturer was advised of these opinions but is unwilling to change the name, for business reasons. The acceptance of this bread is therefore being withdrawn and it will no longer be listed among the accepted foods of the Committee.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

COFFEE EDUCATIONAL ADVERTISING

Sponsor—Bureau of Coffee Information, New York

The Bureau of Coffee Information is supported by the American Can Company, which developed the vacuum process for packing coffee. Its purpose is to disseminate information about coffee.

Advertising—The advertising of this bureau is intended to promote the distribution of ground coffee in tins sealed under vacuum. The advertising provides general information on coffee, commencing with its cultivation and including various steps up to the final distribution of the roasted coffee "sealed in vacuum" in tins.

Investigation shows that freshly roasted coffee immediately sealed in vacuum in tins does not become stale in the unopened package. In this manner it is possible to deliver fresh coffee to the consumer at all times. After the can has been opened, the coffee stales as does any coffee exposed to the atmosphere.

The staleness or freshness of roasted coffee is correlated with the retention of carbon dioxide and carbon monoxide within the coffee bean. Coffee that has lost these retained gases has

also lost its freshness and possesses flavors defined as "staleness." Coffee that is quickly sealed in tins immediately after roasting retains in large measure its absorbed gases. The packing of roasted coffee in "vacuum" in tins prevents oxidation of coffee oils contributing to the well known staleness flavors.

The main advertising booklets are entitled

Coffee Facts for Homemakers
The Story of Coffee
Coffee from Tree to Consumer
What Flavor Measurement Reveals About Keeping Coffee Fresh
The Coffee Problem
The Song of the Coffee Bird
Loose Leaflets giving information on the culture, roasting and packing of coffee and brewing of coffee beverage

CERTIFOODS CERTIFIED NURSERY FOODS— VEGETABLE PUREE

VITAMIN CONTENT GUARANTEED, NO ADDED
SEASONING OR SUGAR

Distributor—Certifoods, Inc., New York, a subsidiary of the Maltine Company, New York.

Packer—Curtice Brothers Co., Rochester, N. Y.

Description—Sieved vegetable mixture containing carrots, spinach and tomatoes prepared by methods efficient for retention in high degree of the natural mineral and vitamin values, no added seasoning or sugar.

Manufacture—Definite proportions of carrots, spinach and tomatoes, prepared as previously described (THE JOURNAL, Feb 17, 1934, p 539), are mixed, heated to 71 C, sieved in an atmosphere of nitrogen gas, canned, processed and packed as described for Certifoods Certified Nursery Foods—Green Beans (THE JOURNAL, Oct 3, 1931, p 1003). The processing is for forty minutes at 116 C.

An alternative is the use of previously canned materials packed in No 10 tins, which are subsequently treated as described above.

Vitamins—The methods of preparation, sieving and processing are efficient to conserve the natural vitamins in high degree.

The product is guaranteed to contain 560 units of vitamin A (Sherman method), 3 units of vitamin B (Chase and Sherman method) and 3 units of vitamin G (Bourquin and Sherman method) per ounce.

Claims of Manufacturer—See this section for Certifoods Certified Nursery Foods—Green Beans (THE JOURNAL, Oct 3, 1931, p 1003).

GOLDEN STATE BRAND UNSWEETENED EVAPORATED MILK

Manufacturer—Golden State Company Ltd., San Francisco.

Description—Canned unsweetened evaporated milk.

Manufacture—The milk is collected and concentrated according to standard procedures (THE JOURNAL, April 16 1932, p 1376).

HERSHEY'S MILK CHOCOLATE AND ALMONDS

Distributor—Chocolate Sales Corporation, Hershey, Pa.

Manufacturer—Hershey Chocolate Corporation, Hershey, Pa.

Description—Milk chocolate containing cane sugar, milk, cacao butter, chocolate and roasted almonds.

Manufacture—Milk chocolate (prepared as described for Hershey's Milk Chocolate (THE JOURNAL, Feb 24, 1934, p 606)) is admixed with almonds, roasted in cacao butter, molded into bars and automatically wrapped in aluminum foil.

Packer—Hawaiian Pineapple Company, Ltd., San Francisco.

Description—Canned pineapple packed in concentrated pineapple juice with added sucrose. The same as Dole Hawaiian canned pineapple products (THE JOURNAL, April 8, 1933, p 1106, and April 29, 1933, p 1338).

PRUDENCE READY TO BROWN BEEF LOAF (PORK ADDED) WITH GRAVY

Manufacturer—Boston Food Products Company, Boston.

Description—A meat loaf prepared from United States inspected and passed by Department of Agriculture beef and pork, cracker meal, beef extract flour, seasoning (sodium chloride, onion, white pepper) and potassium nitrate.

Manufacture—United States inspected and passed by Department of Agriculture lean beef and pork cured with potassium nitrate, trimmed of gristle, sinews and other inedible matter, and peeled and sliced onions are coarsely chopped, cracker meal and gravy prepared from beef extract, flour and seasoning are added and the mixture is finely chopped and automatically filled into cans, which are sealed and processed.

A COMPARATIVE STUDY OF CLINICAL BISMUTH TREATMENTS

The extensive use of bismuth as a spirocheticide in the treatment of syphilis is comparatively recent. It has been recommended in particular for obstinate cases wherein it is regarded by some as probably superior to mercury. According to expert students¹ of the subject, the clinical efficiency of treatment with bismuth compounds in syphilis has been sufficiently demonstrated by all the available methods—by clinical progress, by the disappearance of spirochetes from lesions, and by the reversal of the Wassermann reaction. Many compounds and preparations of bismuth have been employed, so that the question of choice has come to the forefront. This is particularly true because the soluble preparations involve the danger of absorption of poisonous amounts of bismuth. According to Sollmann, Cole and Henderson¹ it may be presumed that compounds which differ in solubility differ also in rapidity of absorption, and therefore of excretion, and in promptness and duration of action. If continued action is essential, as seems probable, too rapid absorption would necessitate frequent injections, and slow absorption would not only delay the effect but tend to produce cumulation and toxicity.

The extensive investigations¹ recently reported from the School of Medicine of Western Reserve University in Cleveland have thrown some light on the physiologic aspects of the action of bismuth in some of its manifold current dosage forms. The procedure was based on the thesis that since the intensity of the excretion of bismuth is determined chiefly by the concentration in the plasma, the urinary excretion especially is a fair index of the actively circulating bismuth, and this is probably the effective bismuth, for, as with mercury, the action seems to cease promptly after the administration is discontinued, when there are still considerable amounts of bismuth fixed in the tissues. Assuming, then, that the urinary excretion of bismuth reflects the

concentration of the active element in the blood, the new data were secured from human patients through careful chemical analyses of the excreta. They lead to the conclusion that the resemblance between the different bismuth compounds is more striking than the differences, except for bismuth subsalicylate.

The various bismuth preparations differ materially as to speed of absorption. The watery solutions stand first, followed in order by oil solutions, oil suspensions of the tartrate, and finally oil suspension of the salicylate. According to the duration of the excretion, and therefore of the concentration and action, the sequence runs in inverse order. The height of the concentration and the total amount of bismuth excreted, which together represent the intensity of the action, are fairly parallel and depend more on the dosage and the frequency of the injection than on any other factor, the salicylate, however, occupies a special position. It appears undesirable, since its absorption is both too slow and too persistent. The fecal excretion of bismuth seems to be only about a tenth of the urinary excretion and fairly parallel to it. The Cleveland investigators have presented clear indications of the relation of the types of compounds now in use to the concentration of active bismuth in the blood secured by their use. As Sollmann and Cole clearly point out, however, this is not all that must be taken into consideration in the bismuth therapy of syphilis. Clinical usefulness includes other factors, such as pain of administration, convenience and cost, which were not involved in their inquiry.

VASODILATATION OF THE EXTREMITIES

In considerations of peripheral vascular disease it is becoming increasingly important to differentiate clearly between organic occlusion of the vessels and vascular spasm. Obviously the latter is conceivably subject to modification through the nervous connections that control to a considerable extent the vasomotor mechanisms of the extremities or other regions involved. In a lecture delivered before the Royal College of Surgeons of England as early as 1858, soon after Claude Bernard's classic studies on the vasomotor constriction functions of the sympathetic nervous system, Brown-Sequard¹ remarked "In those cases of gangrene in which no obstruction has been found after death in the vessels of the dead parts, it is extremely probable that a long persistent spasm of the blood vessels has existed." Of late, various methods have been proposed to determine early in the course of peripheral vascular disease whether the diminished flow of blood to an extremity is due to simple arterial spasm or to obliterative structural disease of the blood vessels. Scott and Morton²

of the University of Rochester Medical School have noted, in their studies of sympathetic activity, that the hyperthermia following the parenteral administration of a foreign protein was long ago advised as a method of treatment in many conditions, among them the peripheral vascular diseases. Brown³ applied this reaction to the diagnosis of these peripheral vascular diseases, deriving a vasomotor index from a comparison of the increase in surface temperature of the foot with the increase in body temperature. This method offered the first differentiation of spasm and occlusion in the involved area. It has been described as disagreeable to patients inconvenient to the physician, and in some cases actually attended with serious complications.

Scott and Morton's study of the sympathetic influence on the vascular system has brought to light a fundamental difference in the control of the peripheral and the splanchnic arteries. The usual surgical depth of general anesthesia entirely obliterates vasoconstriction in the extremities, while it scarcely affects that of the splanchnic area. This seems to be dependent on an anatomic or, more probably, a phylogenic difference in the vasomotor control for these regions. The vasodilatation resulting from nerve block, general anesthesia or spinal anesthesia has its limitations as a clinical procedure. Landis and Gibbon⁴ of the Hospital of the University of Pennsylvania have recently pointed out that the several tests of peripheral vasodilatation at present in use, though different in method, are similar in principle. The surface temperature of the distal portion of the cool, exposed extremity is measured thermo-electrically. Dilatation of the peripheral vessels is then produced and the rise in surface temperature is recorded. The level to which the temperature rises with complete vasodilatation has been determined in persons with normal peripheral circulation. If the surface temperature fails to reach this normal level in a room at suitable temperature, the arteries supplying the part are regarded as being unable to dilate owing to organic changes in their walls.

An exceedingly simple procedure for producing vasodilatation in the lower extremities has been investigated by Gibbon and Landis.⁵ They observed that immersing the forearms and hands in warm water produced vasodilatation in the lower extremities. In ten observations made on the spontaneously cool lower extremities of six normal subjects, the temperatures of the toes began to rise within fifteen minutes after the forearms were immersed in warm water. In all but one of these observations the surface temperature reached 32 C (89.6 F) within twenty-nine minutes after the forearms were immersed. In every instance the surface temperature exceeded 31.5 C (88.7 F),

which Morton and Scott regarded as the minimum normal response to spinal and general anesthesia. In an extension of their studies, Landis and Gibbon⁴ remark that to produce vasodilatation by this relatively simple procedure requires no special apparatus and causes much less discomfort to the patient than the injection of typhoid vaccine or the induction of spinal or general anesthesia. Heat has been used also by Lewis and Pickering⁶ and by de Takats,⁷ but special apparatus is required in the methods employed by them, the body being warmed in an electrical cabinet in the former case and by means of diathermy apparatus in the latter.

As an illustration of the practical application of the procedure of Landis and Gibbon, involving immersion of the forearms of patients in water at from 43 to 45 C (109.4 to 113 F), a statement of their observations may be cited. In seven patients with pain, coldness or cyanosis of the lower extremities, the temperature of the toes rose to levels above 32 C (89.6 F). This normal response definitely excluded the possibility of obliterative structural disease of the arteries as a cause of the diminished flow of blood in the lower extremities. Fourteen patients with thrombo-angitis obliterans or arteriosclerosis involving the lower extremities showed varying grades of organic occlusion and spasm when tested by this method. In eight of the thirteen patients who failed to show the normal vasodilator response to warming the forearms, the results were compared with those obtained by some other method of producing vasodilatation, including the intravenous injection of typhoid vaccine, the use of spinal anesthesia and anesthetization of the posterior tibial nerve. In seven of the eight patients the clinical interpretation of the results by the two methods was the same.

In their recommendation of their entirely unobjectionable technic the Philadelphia investigators conclude that, if the surface temperature of the toes rises above 31.5 C, significant obliterative structural disease of the arteries of the lower extremity is definitely absent. If the surface temperature fails to rise to this level, organic arterial obstruction is probably present. With controlled room temperature, the approximate grade of the organic obstruction is indicated by the difference between 31.5 C and the maximum temperature reached. For absolute certainty in the diagnosis of organic arterial obstruction the abnormal vasodilator responses obtained by warming the forearms should be confirmed by some other method of producing peripheral vasodilatation. Equally recent is the procedure involving the study of the peripheral pulse volume by means of the plethysmometer of Johnson.⁸ It records the pulse

volume of a digit as shown by the height of pulse waves in specially prepared tracings. According to Scupham and Johnson⁹ of Northwestern University Medical School, in persons suffering from occlusive disease of the arteries of the extremities the pulse volume wave deviated sharply in size and contour from that obtained in normal persons. The method is an objective one, more direct, it is asserted, and in some respects more reliable than the determination of skin temperature. The procedure is simple and easy of application, and with it permanent records may be obtained for accurate subsequent comparison. It is believed to be applicable, as a criterion, to all the methods for differential diagnosis between organic occlusion and angiospasm, in the same manner that determinations of skin temperature are now used. It is valuable in the determination of occlusion in the smaller arteries of a digit when other methods are not applicable. Evidently the study of peripheral vascular disease is entering on a productive period that is likely to initiate real progress in a difficult field of clinical medicine.

FURTHER EVIDENCE OF THE DISTRIBUTION OF INTESTINAL AMEBAS

Amebic dysentery became recognized as a distinct disease entity as the result of the investigations of Councilman and Lafleur in the United States in 1891. For many years it was relegated to the province of tropical medicine, because of the conspicuous incidence of intestinal amebiasis in the warmer climates. Nevertheless, in their *Human Protozoology*, published ten years ago, Hegner and Taliaferro¹ remarked that infestation with *Endamoeba histolytica*, the parasite of amebic dysentery, can no longer be considered tropical but is world wide in distribution. In fact, we can sum up the geographic distribution of all the entozoic amebas of man, they add, by saying that they all occur, in different percentages in each species, wherever man occurs. In discussing the problem of amebiasis, Craig² noted the probability that more than 5 per cent of the people of the United States harbor *Endamoeba histolytica*, and it is not unlikely that the incidence in the more southerly states is even higher. The discovery of many cases of amebic disease as well as carriers in Chicago last fall and the attendant publicity served to focus attention on a much neglected menace to health.

In such situations, to be forewarned is to be forearmed. A survey³ recently made at the University of Pennsylvania on more than a thousand college freshmen showed from the examination of a single stool per person that 4.1 per cent of these students harbored

Endamoeba histolytica. Repeated stool examinations probably would have shown a still higher incidence. Most of these young persons came from homes in Pennsylvania or New Jersey, and few had traveled extensively either in the United States or abroad. It is likely that these students became infested before coming to college, so that the incidence found indicates the presence of the parasite in these districts.

Obviously, most of the students harboring *Endamoeba histolytica* were "carriers." As the Philadelphia investigators point out, just why some persons when infested with this ameba become ill, while others do not, is not exactly known. It seems probable, however, that some individuals have a greater natural resistance to this parasite than others and also that some strains of the parasite may be more virulent than others. Wenrich, Stabler and Arnett offer some salient advice that is deserving of repetition. As amebic dysentery is considered to be rare by many medical men, the true nature of such cases is likely to be overlooked. Amebic disease is admittedly difficult to differentiate from other disturbances of the digestive tract and normally requires the finding of the amebas themselves in the feces or in the tissues obtained at necropsy. With four other amebas resident in the human bowel, proper diagnosis requires special training in the technique of examination and in the differentiation of these different types of parasites. Education on the part of the public as well as of health officials is eminently desirable. Experience has taught that early recognition of the causes of disease is one of the most effective helps not only in treatment but also in the framing of effective prophylactic measures.

Current Comment

BONE DEVELOPMENT IN SUNNY PUERTO RICO

Occasionally one hears an ironical comment on the importance of sunlight for human well being. This is not surprising in view of the confusion and uncertainty that still exist with respect to the medical or physiologic aspects of climatology. Adverse criticism, furthermore, is a justifiable and almost inevitable consequence of the exploitation of sunlight and its artificial substitutes in the form of apparatus designed to produce special types of radiant energy. There has been all too much quackery and pseudoscience about solar irradiation. Nevertheless, one could scarcely expect to find a more convincing demonstration of what sunshine actually can accomplish than is afforded by the data of Eliot and Jackson¹ on the bone development of infants and young children in Puerto Rico. Rickets is undoubtedly a rare disease in that land of intense sunlight. The study included nearly 600 Puerto Rican children from 1 to 34 months of age. The observations were made in a thoroughgoing manner and included roentgeno-

graphic appearance of the bones and analyses of the blood. Only five cases of rickets were detected, an incidence of less than 1 per cent. Even some of these exceptions were readily explained. One was a case of frank severe rickets, that of a 7 months old infant who had lived all his life in a stone cellar lighted only with electric light, and another, a case of healed rickets that had occurred when the child lived in New York City. The Puerto Rico climate is characterized not only by the intense character of the sunlight but also by its uniform availability throughout the year. Although the average number of hours of sunlight during a year in San Juan does not greatly exceed the average number in some Northern cities, its availability is much greater. In San Juan the daily average of hours of sunlight varies relatively little from month to month (from 6.8 in December to 8.4 in August), and the uniformly warm climate allows the hours of sunlight to be constantly available to children throughout the year. In the northern part of the United States, on the other hand, not only is there a considerable variation from month to month in the daily average of hours of sunlight, but the long cold season reduces to a minimum the availability of what sunlight there is for at least five months in the year. It should also be remembered as has been shown by Tisdall and Brown, that the intensity of the sunlight probably is relatively great and varies little from season to season at the latitude of Puerto Rico (18 degrees), whereas in northern American cities (around 40 degrees) the intensity, without much doubt, is considerably lower during the winter months. Eliot and Jackson state that if one takes into consideration the uniformly warm climate, the intensity of the sunlight and its availability for many hours daily throughout the year and the outdoor habits of the people, the presumption that the children of Puerto Rico should be free from rickets would seem to be justified.

THE FAT OF THE FECES

The feces always contain a measurable amount of "fat" or lipid material, regardless of whether any fat has been ingested. During fasting the "fat" fraction of the excreta from the alimentary tract may amount to one third of their dry weight. Formerly the fecal fat was attributed to two sources: food fat that had failed to be digested and absorbed, and fat from the bacteria and cellular debris of the digestive canal. More recently the evidence has accumulated to indicate that a certain amount of fat is actually excreted through the intestine independent of the other factors mentioned. This general view is championed by Bloor and his school. They cite the fact that the fecal lipids of animals are excreted in constant amount and are of a uniform type, regardless of the quantity of fat in the diet or its degree of unsaturation (iodine number). Because of their similarity in composition, Sperry¹ believes that the fecal lipids represent a secretion or excretion from the blood. This investigator showed also that the bile,² epithelial desquamation³ and prob-

ably bacteria⁴ are not the sole source of fecal lipids. It is known that sterile meconium obtained from newborn infants shows the presence of fatty material. At the Royal Victoria Hospital in Montreal, Krakower⁵ has compared the composition of the fecal lipids in a group of normal persons who received test diets containing small and large amounts respectively of fat. Despite the wide variations represented by such extremes as 8 and 128 Gm of fat daily, the excreted lipids were uniform in composition, as judged by their iodine numbers, and thus differed from the fats fed in which the values varied from 82 to 125.8. The independence of the stool lipids was further shown by the comparatively slight relationship in the amounts of fat in the diet and those recovered in the feces. It is hard, therefore, to avoid Krakower's conclusion that fecal lipids do not represent a residue of fat in the diet, when given in moderate amounts, but may be in part excretions of the blood into the gastro-intestinal tract. These assumptions need to be kept in mind in the clinical examination of the stools.

Medical Economics

NEW FORMS OF MEDICAL PRACTICE

Some California Health Insurance Rackets

In a series of articles in *THE JOURNAL* which began in October 1932, the Bureau of Medical Economics emphasized certain dangers and abuses likely to be associated with attempts to apply the insurance principle to medical care.

Some of the dangers then suggested were the following:

1 Profit making plans in this field could easily degenerate into fraudulent "rackets."

2 Practically all the plans lacked provisions to insure financial security. There was seldom any provision for reserves such as experience has shown are a first essential of any insurance plan.

3 Owing to the lack of sound financial provisions, the subscribers to such plans had no security that they would receive anything in return for payment collected.

4 The presence of numerous such schemes operating in the same field would inevitably create commercial competition. The easiest way to meet such competition is to reduce the quality of the service. To do this is comparatively safe, because the customer cannot judge that quality and nearly every scheme resisted any suggestion for professional supervision of the quality of the service. Such supervision has been long recognized as the only method of maintaining high standards in hospital and educational institutions, both of which are less affected by competition and may be supposed to have greater incentives to maintain proper standards.

5 It was predicted that, although such plans were always proposed as a method of reducing the costs of medical care, their first effect was to take a large share of the subscribers' money for lay management and especially for solicitation of members. Experience in other countries had shown that, in such a conflict over the patient's dollar, the share going for the payment of medical service was continually reduced to increase the proportion taken for those to whom the scheme was only a method of securing income.

6 Emphasis was placed on the historically established fact that all solicitation for medical service inevitably led to a deterioration of almost every phase of that service.

7 Such schemes, looking on the physician as a mere instrument in a commercial transaction, always lead to such unjust

and excessive exploitation of the physician as to weaken or destroy professional standards

When these articles were published, promoters and defenders of these plans criticized the Bureau of Medical Economics sharply for its conclusions. They charged that the Bureau had drawn on its imagination in order to build objections. The truth is that every such objection was based on examination of existing systems in which these evils had already begun to develop.

The Report of the Committee on the Costs of Medical Care seems to have been instrumental in starting a flood of such schemes.

In the few months that have elapsed, there has been an opportunity for all these evils to develop. They have developed faster and in more vicious directions than the Bureau had predicted.

California was hailed by the defenders of these new forms of medical practice as pointing the way to be followed by the rest of the country. This state became the happy hunting ground of the medical promoter. Now the Alameda County grand jury has indicted nineteen men in connection with the "health insurance racket" which, as the *San Francisco Chronicle* says, has victimized hundreds of persons throughout the state. Three of those indicted are now either in jail or out on bonds of from \$5,000 to \$20,000, while officers are seeking to find the remainder in order to arrest them. The *Chronicle* continues: "The first indictment contained two counts, one of conspiracy to commit petty theft, the other conspiracy to violate the insurance laws. The second indictment charges conspiracy to make false promises. All three offenses are felonies, each punishable by two years' imprisonment or a \$5,000 fine, or both."

This investigation was largely inspired by Dr. Charles B. Pinkham, secretary-treasurer of the Board of Medical Examiners for the State of California. He has been investigating the operations of such organizations for some time. He discovered that fourteen of these so-called hospital associations were connected in one way or another with a single room in the Phelan Building, San Francisco.

Assistant District Attorney Leslie G. Gillen was quoted by the *San Francisco Examiner* of April 30, 1932, as saying after the investigation that between 4,000 and 5,000 persons are making payments of from \$1 to \$5 a month into health and hospital organizations that are either suspended from business or do not exist as far as the state of California knows.

It is significant that it took nearly a year after these facts had become known before the present grand jury action was secured. This would seem to indicate that these swindling associations had become sufficiently powerful to wield political influence.

In a list compiled by Dr. Pinkham Jan. 29, 1934 are found the names of 143 such associations. The investigation showed that thirty-seven of these used two or more names. While this is not a proof of fraudulent intent, it is at least a suspicious fact that a corporation or business firm finds it necessary to change its name one or more times within the short period the organization has been in existence. Something of the character of the service being given by those that even pretend to meet their obligations is shown by some of the facts unearthed during this investigation.

Of one association, it is said, it is reported that 'the office girl prescribes for members seeking medical service, that Drs. — and — have prescriptions already compounded and the office girl gives them to policyholders.'

The complaints of failure to provide medical service had been investigated by the grand jury in two other cases.

The representative of another medical service concern had been arrested for violation of the medical act.

One subscriber complained that after paying \$4.50 a month for three years he was refused medical treatment for his baby.

The attorney general said about one contract: 'I am of the opinion that the issuance thereof not only violates the law relating to insurance companies but the Medical Practice Act, as well as the State Bar Act.'

Another organization that contracted to furnish all forms of medical service reported a staff of two physicians, four dentists, four chiropractors and one chiroprapist.

A view of the character of the service furnished, as revealed by the state board of medical examiners, is given in the report of the *San Francisco Chronicle* for Feb. 21, 1934.

According to Inspector J. W. Davidson of the board the doctor sent to see her by the health association said the intestinal ailment of which she complained was imaginary. Within a week she was dead in the county hospital and of that ailment. The company did not pay.

Inspector Davidson tells also of the company that stipulated it would deliver a baby free for any couple that had held their policy for two years. One young couple thought they had qualified. They waited two years and then prepared for the baby.

When the baby was about to arrive they notified the company, asking for the promised service. Did they get a baby free? They did not. The company called attention that they had once been eleven days late in payment of a premium and that in accordance with section Q line 6 of the contract they would have to wait two years from the time the delinquent premium was paid.

In other words said Davidson they would have to postpone the baby.

The *Underwriters Report* a weekly insurance paper of San Francisco, in its issue of Feb. 15, 1934, describes the financial condition of one such company as follows: "Special agents of the State Medical Board raided the offices of the United Travelers Underwriters in San Francisco two weeks ago, at which time they confiscated two thick files of complaints from irate and gipped policyholders and learned that the insurance company had exactly \$140 in liquid assets against \$70,000 of insurance in force. The raiding officers were unable to serve their warrants because the 'John Does' had fled. They were arrested later in Reno."

Another scheme distributed paid-up memberships to be given out by commercial houses in Long Beach which entitled the holder to one year of benefits.

Harry Kramer who has recently been indicted and whose bond was fixed at \$20,000 was operating at least seven different organizations.

There is a long list of physicians who have permitted their names to be used by such organizations and who, in some cases, undoubtedly have destroyed reputations built up through years of practice.

As a result of this sudden growth of medical insurance schemes in California many thousands of people have been defrauded of money which they thought they were paying for medical service. They have probably been deprived of medical service except so far as physicians and existing relief organizations have come to their assistance. If the money thus collected, and even worse than wasted, is to be counted as a part of the cost of medical care, it is quite evident that these organizations, so far from having reduced that cost, have greatly increased it.

It would be hard to find a better illustration of the evils that inevitably follow the introduction of lay control, the profit motive and solicitation into the field of medical service.

CALIFORNIA

Outbreak of Botulism—Five members of a Japanese family in Santa Clara County died, recently, of botulism contracted through an unusual source, according to the state health department. All members of the family partook of a meal, Dec 28, 1933, at which a soy bean preparation was consumed. This preparation had been made December 26 and cooked four hours on the stove, after which it was buried in a cloth sack and placed in a heated pit in the ground for two days to allow fermentation. Laboratory examination of the mixture proved positive for botulism.

Dr Ely Retires—Dr Leonard W Ely, since 1913 professor of surgery, Stanford University School of Medicine, will retire from the faculty at the end of the present academic year. Dr Ely was born in Brooklyn in 1868 and graduated in medicine at Columbia University College of Physicians and Surgeons. He engaged in private practice in New York and also in Denver and is the author of several volumes on diseases of the bones and on tuberculosis. To fill the vacancy in the department, Dr Donald E King, formerly of Ann Arbor, has been appointed an associate professor in orthopedics. He will assume his duties September 1.

Society News—Dr Arthur Elmer Belt, among others, spoke before the Los Angeles Surgical Society, March 9, on "Electrical Cutting—Its Remote Effect on Tissue, with Particular Reference to Electrosurgical Resection of the Prostate."—At a meeting of the San Francisco Pathological Society, March 5, the speakers included Dr James B McNaught on "Rupture of the Pulmonary Artery."—At a meeting of the Clinical and Pathological Society of Los Angeles, February 22, speakers included Drs Henry Snure and George D Maner on "Carcinoma of the Stomach with Unusual Bone Metastases."—Dr Eberle Kost Shelton, Santa Barbara, addressed the Hollywood Academy of Medicine, February 15, on "The New Growth Hormone."—Speakers before the Society for Neurology and Psychiatry, February 21, in Los Angeles, were Drs Nelson P Anderson on "Adenoma Sebaceum with Tuberos Sclerosis," Verne R. Mason, "Exophthalmos," and Cyril B Courville, "Mortality of Injuries to the Head."—Dr Harry M Weber, Rochester, Minn, spoke on "Roentgen Manifestations of Tumefactive Processes in the Large Intestine and Their Differential Diagnosis" before the San Diego Academy of Medicine, February 21.

COLORADO

Society News—Dr Cuthbert Powell, Denver, addressed the Boulder County Medical Society, March 8 on "Value of X-Ray Diagnosis in Obstetrics."—Severance Burrage, Dr PH, spoke before the Medical Society of the City and County of Denver, March 6, his subject was "Microbial Fingerprints—Their Relation to Respiratory Disease." The Rocky Mountain Pediatric Society sponsored the program of the society, February 6, Dr Henry F Helmholtz, Rochester, Minn, was the guest speaker, on "Pyelitis in Children."

DISTRICT OF COLUMBIA

Medical Bills in Congress—Changes in Status S 2006 has been reported to the House without amendment (H Rept 900). The bill authorizes the Commission on Licensure of the District of Columbia to issue a license to Della D Ledendecker to practice chiropractic in the District. **Bills Introduced** S 3045 introduced by Senator Davis, Pennsylvania, proposes to provide for needy blind persons of the District of Columbia.

FLORIDA

Business Bureau Organized—The Lake County Physicians Business Bureau, sponsored by the county medical society, has been organized to collect and adjust accounts for its members and establish and maintain friendly relations between members and their patients.

Personal—Dr Leonidas M Anderson Lake City, was recently presented with the medal awarded annually by the local chapter of the American Legion for distinguished service and citizenship based upon peace time service to the community.

Dr Anderson is now president of the Columbia County Medical Society and a past president of the Florida Medical Association.—Dr Thomas S Kennedy, sanitary officer of the West Florida district, has been appointed assistant state director of rural sanitation.

Society News—The Florida State Board of Health conducted a tuberculosis clinic in Fort Pierce, February 16, Dr William A Claxton was in charge.—Dr Walter B Lancaster, Boston, addressed the Tampa Eye, Ear, Nose and Throat Society, February 14, on "Certain Disturbances of Binocular Vision and Their Treatment" and "The Ultracapsular Method of Cataract Extraction."—Dr Henry E Palmer, Tallahassee, was elected president of the Association of Seaboard Air Line Railway Surgeons, recently.—At a meeting of the De Soto-Hardee-Highlands County Medical Society in Bowling Green, January 9, Dr James R Boulware, Jr, Lakeland, discussed "The Use of Phenobarbital in Infancy."—A symposium on indigestion, or dyspepsia, constituted the program of the Duval County Medical Society at its meeting, February 6, speakers were Drs Ernest B Milam, Clayton E Royce, Harry A Peyton, Herrman H Harris and Harry B McEuen.—Dr James O Wallace, Pittsburgh, spoke before the Dade County Medical Society, February 2, on "Defangements of the Knee Joint," and Max Dobrin, Miami, "Diabetes Mellitus in Relation to the Pituitary Gland."

GEORGIA

Dr Moss Resigns as Dean—Dr William L Moss has resigned as dean of the University of Georgia Medical Department, Augusta, it has been announced. He was named to the position in July 1931. Dr Moss was graduated from Johns Hopkins University School of Medicine in 1905 and has been a member of the medical faculties of Harvard and Yale universities. In 1916 he was in charge of a Harvard expedition to Peru and in 1920 was a member of a Harvard commission to the Dominican Republic (THE JOURNAL, June 27, 1931, p 2216). Dr G Lombard Kelly, professor of anatomy, was named vice dean in charge of administration, it was stated. Dr Moss has also resigned as professor of preventive medicine, it was reported.

Society News—At a meeting of the Muscogee County Medical Society, February 8, Drs Clifford A Peacock spoke on "Diseases of the Eye in Relation to Systemic Disease", Francis B Blackmar, "Edema of the Optic Disk," and John B Thompson, Jr, "Diseases of the Ear and Mastoid in Relation to Systemic Disease."—Dr William A Selman presented a paper on "Carcinoma of the Colon" before the Fulton County Medical Society, Atlanta, February 15.—At a meeting of the Atlanta Neurological Society, February 22, Dr Ross M Chapman Towson, Md, spoke on "Mental Hygiene and the Public Health" and Dr S Bernard Wortis, New York, "The Convulsive State."—At a meeting of the Ware County Medical Society February 7, Dr Daniel M. Bradley, Waycross, gave a paper on "Treatment of Menstrual Disturbances."—A joint paper on "Infantile Paralysis—From Medical and Orthopedic Standpoints, with Particular Reference to Cases Treated in Macon" was presented before the Macon Medical Society, February 6, by Drs William C Boswell and John I Hall, both of Macon.

ILLINOIS

Dr Starkel Honored—Friends of Dr Charles H Starkel, Belleville, gave a dinner in his honor, February 14, at the University Club in St Louis, to observe his completion of fifty years in the practice of medicine. Dr Starkel, who is 72 years old, graduated from Rush Medical College in 1884. He was health commissioner of Belleville for many years.

Society News—Dr Ko K. Chen, director of pharmacologic research Lilly Research Laboratories, Indianapolis, addressed the Peoria City Medical Society, March 6, on "Development of Ephedrine," "Newer Antidotes for Strychnine and Cyanide Poisoning" and "Toad Poisons."—The St Clair County Medical Society was addressed in East St Louis March 1, by Dr Charles H Neilson, St Louis, on "The Weather, Its Influence on Health and Disease" and in Belleville, March 7, by Dr Cleaves Bennett, Champaign, on "Care of Indigent Sick as Done by Adams Champaign, Cole and Macon County Medical Societies."—Speakers before the Adams County Medical Society at Quincy, March 12, were Drs Philip H Kreuschner, Chicago, and Nathaniel G Alcock, Iowa City, on "Backache" and "Prostatic Resection," respectively.—Dr Joseph Marcovitch Jacksonville, spoke before the Morgan County Medical Society, February 8 on "Symptoms and Clinical Findings in Postepidemic Encephalitis," and Dr Warner H Newcomb, Jacksonville Treatment of Cardiac Decompensation."

Chicago

Program on Poliomyelitis—"Orthopedic Care of Poliomyelitis" will be the subject presented by Dr. Michael Hoke, surgeon-in-chief, Georgia Warm Springs Foundation, Warm Springs, Ga., before the Chicago Medical Society, March 28, in the Medical and Dental Arts Building. The society devoted its meeting, March 21, to a discussion of milk. Speakers were Paul Krueger, assistant director, bureau of dairy products, Chicago Board of Health, A. M. Krahl, director, public relations, Pure Milk Association, M. O. Maughn, executive secretary, The Milk Council, Inc., Dr. Roy R. Ferguson, secretary, Chicago Medical Society Milk Commission, and Mr. Raymond Hertwig, secretary, Committee on Foods of the American Medical Association. H. L. Russell, Ph.D. director, Wisconsin Alumni Research Foundation, discussed 'Irradiated Vitamin D Milk.'

INDIANA

Dinner to Dr. Wishard—The senior class of Indiana University School of Medicine held a dinner in honor of Dr. William N. Wishard, February 28, in celebration of his sixtieth anniversary as a graduate of medicine. Dr. Wishard is professor of genito-urinary surgery at the medical school and a former superintendent of the Indianapolis City Hospital. His father, Dr. William H. Wishard, made the first formal effort to obtain a general state hospital by resolution introduced in the session of the Indiana State Medical Association in 1868, it is reported. A son, Dr. William N. Wishard Jr., is associated in practice with him.

Society News—The Indianapolis Medical Society held a joint session with the midwestern section of the American Congress of Physical Therapy, March 13, speakers were Drs. Max Thorek, Chicago, on "An Electrosurgical Method for Obliterating the Gallbladder," and John Stanley Coulter, Chicago, "Physical Therapy in the Rehabilitation of the Disabled." The society was addressed, March 20, by Dr. Lowell T. Coggeshall, Chicago, on "Diagnosis and Treatment of Lobar Pneumonia." Speakers before the society, February 20, were Drs. John W. Carmack, Indianapolis, and Ernest O. Asher, New Augusta, on "Suppuration in the Petrous Portion of the Temporal Bone" and "Bedside Observations on Prognosis," respectively. The society was addressed February 27, among others, by Dr. Carl Habich on "Gonorrhea in the Female."

IOWA

Society News—Dr. Oscar R. Prettyman, Manson, discussed urinalysis before the Calhoun County Medical Society in Rockwell City, March 13.—At a meeting of the Chickasaw County Medical Society in New Hampton, February 2, Dr. Erwin von Graff, Iowa City, spoke on "Dangers of Stump Cancer after Subtotal Hysterectomy."—A symposium on the upper respiratory tract constituted the meeting of the Hardin County Medical Society; the speakers were Drs. Ralph H. Parker and George A. May, both of Des Moines.—Dr. Paul B. Magnuson, Chicago, discussed the surgical treatment of arthritis before the Scott County Medical Society in Davenport, February 6.—At a meeting of the Tama County Medical Society in Dysart, February 23, Drs. Thomas F. Hersch and Ernest G. Kieck, Cedar Rapids, spoke on common colds and their prevention and common skin diseases, respectively.—The Wapello County Medical Society will be addressed, April 3, by Dr. William E. Olson, Ottumwa, on "Correlation of Simple Laboratory Procedures with Clinical Findings as an Aid to Diagnosis." Dr. Myron G. Means, Ottumwa, spoke before the society, March 20, on "Catarrhal Jaundice."—Recent speakers before the Wayne County Medical Society included Dr. Robert O. Hughes, Ottumwa, on "Diagnosis of Acute Diseases in Children."

KANSAS

Credit Bureau Established—Members of the Sedgwick County Medical Society are participating in the recently established Wichita Medical Credit Bureau. In designating the accounts to be listed with the bureau, the committee on medical economics of the society demands that individual members shall not use their own judgment as to what bills are delinquent. All accounts over ninety days old must be listed with the bureau. Personal information on file about the patient will be available to participating physicians.

Society News—Speakers before the Clay County Medical Society at Clay Center, February 14, were Drs. George W. Bale and Franklin R. Croson, both of Clay Center, on trichomonas vaginalis and acute intestinal obstruction, respectively.

—At a meeting of the Shawnee County Medical Society, February 5, Dr. Arthur E. Hertzler, Halstead, discussed the present trend in treatment of gonorrhea.—Speakers before the Wyandotte County Medical Society, March 20, were Drs. Charles Omer West and Maurice A. Walker on "Allergy" and "Leucocytosis in Carcinoma of the Stomach." Dr. Harold V. Holter discussed "Lacerations at Childbirth and Their Treatment" before the society, March 6, and Dr. Donald N. Medearis, "Vomiting in Infants." A joint meeting of the society and the Jackson County Medical Society, March 13, was addressed by Dr. W. Lee Hart, Medical Corps, U. S. Army, on "Relationship of the Army to Medicine," Dr. Reuben H. Hunt, Medical Corps, U. S. Navy, "Navy Medical Service in Our Insular Possessions," and Dr. Otto Jason Dixon, "Ear, Nose and Throat Complications in Exanthemata."

KENTUCKY

Bill Passed—H. 662 the uniform narcotic drug act, has passed the house and senate.

Personal—Dr. Amphas W. Davis, Madisonville, has been appointed a member of the state board of health to succeed the late Dr. Ben B. Keys, Murray.—Dr. Oscar M. Crenshaw, Lebanon, recently received a bequest of \$1,000 from a patient "in appreciation for medical services."

Hospital News—St. Anthony's Hospital Association gave a dinner, January 27, in honor of Dr. William Seaman Bainbridge, New York, who described the work of a committee that is collecting and coordinating the medical and surgical experiences of the World War. Dr. Argus D. Willmoth presided at the dinner and addresses were made by Drs. George A. Hendon, Ira N. Kerns, Curran Pope and John R. Wathen, all of Louisville.

MASSACHUSETTS

Bill Introduced—S. 257 proposes to regulate the sale of methyl alcohol, and certain preparations containing alcohol.

Health at Lowell—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended March 10 indicate that the highest mortality rate (24.4) appears for Lowell and that the rate for the group of cities as a whole was 13.2. The mortality rate for Lowell for the corresponding period last year was 13, and the rate for the group of cities, 11.9. The annual rate for eighty-six cities for the ten weeks of 1934 was 12.7 as against a rate of 12.4 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

MINNESOTA

Society News—Dr. Frank S. McKinney, Minneapolis, addressed the Washington County Medical Society at Stillwater, recently on "Modern Treatment of Hernias and Varicose Veins."—Speakers before the Minnesota Academy of Medicine, March 14, in Minneapolis, were Drs. Henry W. Cook and Frederic E. B. Foley on mortality and morbidity trends and operative division of the horseshoe kidney, respectively. Dr. William F. Braasch, Rochester, presented an unusual form of renal polycystic disease.

Dinner to Dr. Schwyzer—Dr. Arnold Schwyzer, St. Paul, was guest of honor at a dinner, February 12, sponsored by the sisters of St. Joseph's Hospital to commemorate his forty-third year at the hospital and his seventieth birthday. He was presented with an illuminated framed parchment by Dr. Samuel C. Schmitt on behalf of the staff. Dr. John A. Lepak was toastmaster, and Dr. William J. Mayo, Rochester, the principal speaker on "Teacher, Physician and Surgeon." Other speakers included Drs. Carl C. Chatterton, who delivered greetings from the hospital, Gustav Schwyzer, "My Brother and Pre American Days in Switzerland," John L. Rothrock, "High Social and Civic Recognition," Justus Ohage, Sr., "Reminiscences," and William C. Carroll, "The Ever Guiding Hand in the Hospital." Dr. George A. Geist who also spoke composed two musical numbers in honor of Dr. Schwyzer.

MISSISSIPPI

Bill Passed—S. 316, proposing to amend the medical practice act, has passed the senate in amended form. As introduced, the bill proposed (1) to require midwives to procure from the state board of health annually permits signed by the secretary of the board and by the county health officers of the counties in which such midwives respectively reside, (2) to redefine

the practice of medicine, and (3) to authorize the state board of health to revoke a license to practice medicine or a license to practice osteopathy, if the licensee (a) procures or aids or abets in procuring a criminal abortion, (b) is habitually intemperate in the use of intoxicating liquor or narcotic drugs or violates the federal narcotic laws, (c) obtains any fee on the assurance that a manifestly incurable disease can be permanently cured, (d) procures by fraud or deceit a license to practice, (e) is convicted of any charge resulting in a penitentiary sentence, or (f) is convicted before a court for crime in the course of professional practice. The board is authorized to reinstate any license that it has revoked.

Bills Introduced—S 469 proposes to authorize the organization of corporations to engage in the business of writing contracts providing for hospital services in cases of illness or accident. H 553 proposes to authorize the Board of Supervisors of Harrison County to make a general levy, not to exceed one half of one mill, on all the taxable property in the county, to provide funds for charitable hospital purposes. H 851 proposes to regulate the practice of podiatry. Podiatry is declared to mean "the diagnosis and medical, mechanical, electrical, and surgical treatment of the minor ailments of the human foot, such as corns, calluses, warts, ingrowing and abnormal nails, bunions, and similar conditions." Podiatrists are to be permitted to use "such mechanical appliances as may be deemed necessary for the relief or cure of such ailments of the feet, except partial or complete amputation of the foot or toes, surgical correction of the various forms of talipes (club-foot) and other deformities of muscles, tendons, bones, and nerves requiring cutting operations, or the use of anesthetics other than local anesthetics related to the part affected used to prevent operative or mechanical pain, provided that massage of the leg in connection with such treatments is not prohibited. Diseases and conditions of the feet produced by kidney, heart, and other systemic diseases are not to be treated by persons licensed under this act." The bill is not to apply to licensed physicians.

MISSOURI

Hospital for Negroes—Construction on the Homer G. Phillips Hospital for Colored, St. Louis, will be resumed through the recent transfer of \$1,500,000 to a hospital fund from funds appropriated for other purposes. Much needed improvements to other municipal institutions will also be carried out as the result of this transfer. The hospital will have 600 beds when completed, and cost \$2,500,000. It is expected to be ready for occupancy about July 1935. The work begun on the structure some time ago was stopped when funds were exhausted.

Society News—The Buchanan County Medical Society was addressed February 7, by Dr. Albert H. Muench, St. Joseph, on sterility. At a meeting of the Cape Girardeau County Medical Society, February 12, Drs. Hugh V. Ashley, Cape Girardeau, and Daniel G. Seibert, Jackson, spoke on placenta praevia and care of pregnancy in the home respectively. Dr. Frank B. Long, Sedalia, read a paper on pernicious anemia before the Pettis County Medical Society, February 19. The medical societies of Howell, Oregon, Texas, Wright and Douglas counties recently merged, forming the South Central Counties Medical Society. Meetings are to be held every two months. At this meeting, the Carter-Shannon County Medical Society was invited to become a part of the new organization. Dr. James C. B. Davis, Willow Springs, was named president, and Dr. Alfred C. Ames, Mountain Grove, secretary. At a meeting of the St. Louis Medical Society, March 2, speakers included Drs. William Carl Stude on 'Perforations of the Labia Minora', Norman Tobias, 'Extragenital Infection in Syphilis', and Frank L. Morse, 'Treatment of Cancer with Pancreatic Extract'. Dr. Jacob William Beckmann will speak on 'Encephalitis B' and discuss the St. Louis epidemic before the St. Louis Neuropsychiatric Society, April 2. Dr. Charles A. Doan, Columbus, addressed the Kansas City Academy of Medicine, March 16, on 'Clinical Implications of Experimental Hematology'.

NEW YORK

University News—It was stated in THE JOURNAL, March 3, page 705, that "Syracuse University College of Medicine has discontinued its department of obstetrics in order to concentrate all its work in Syracuse Memorial Hospital." This sentence should have read 'Syracuse University College of Medicine has discontinued the department of obstetrics in its university owned hospital in order to concentrate all obstetric work in Syracuse Memorial Hospital'.

Bills Introduced—S 1142 and A 1742 proposes to make it unlawful for any business corporation or voluntary association to practice podiatry or to solicit by any method the practice of podiatry, for itself or for any licensed podiatrist. The practice of podiatry, or the advertisement thereof, by any person under any trade name or under any name or designation other than his own, is prohibited. No person, other than a licensed physician, is to be permitted to use in connection with his name the words or terms "foot-specialist, foot-correctionist, foot-expert, practopedist, podologist, or any words or terms of similar import." A 1442 proposes to accord liens to charitable hospitals, and hospitals operated by counties, cities, towns or villages treating any person injured through the negligence of another on any rights of action, claims, counter claims or demands accruing to such person by reason of his injuries. A 1567 proposes to amend the law prohibiting any unvaccinated child from entering a school in a city having a population of 50,000 or more, by providing that a child not vaccinated may be admitted on the recommendation of the board of health or such other board, commission or officers of such city having jurisdiction of the enforcement of the vaccination law.

New York City

Afternoon Lectures in Queens County—Recent Friday afternoon lectures under the auspices of the Queens County Medical Society at the society's building in Forest Hills have been given by the following physicians:

Dr. Milton B. Rosenbluth, Modern Aspects of the Treatment of Pneumonia
Dr. Pol N. Coryllos, Surgical Treatment of the After Effects of Pneumonia
Dr. William Bierman, Office Electrosurgery
Dr. Joseph E. Conner, Recent Advances in Hematology

Discussion of Maternal Mortality—A meeting to discuss the recent report on maternal mortality issued by the New York Academy of Medicine was held, March 7, under the joint auspices of the academy, the New York Obstetrical Society and the Medical Society of the County of New York. Drs. Harry Aranow, George L. Brodhead and George W. Kosmak presented various phases of the report, and the following participated in discussion: Drs. Arthur W. Bingham, East Orange, N. J., Clifford B. Lull, Philadelphia, Thomas Parran, Jr., Albany, state health commissioner, John L. Rice, commissioner of health, Sigismund S. Goldwater, commissioner of hospitals, and Edward C. Podvin.

OHIO

Dr. Corrigan Appointed to Diplomatic Post—Dr. Francis P. Corrigan, Cleveland, has been appointed American minister to El Salvador, Central America. Dr. Corrigan, a native of Cleveland and a graduate of Western Reserve University School of Medicine, has spent much time in Latin American countries. Recently he has been head of the surgical department of St. Alexis' Hospital, Cleveland.

Society News—Dr. Robert C. Austin, Dayton, addressed the Darke County Medical Society, Greenville, February 16, on 'Pitfalls in Abdominal Surgery'. Dr. John T. Quirk, Piqua, addressed the Miami County Medical Society, Troy, February 2, on 'Diagnosis, Chemical Significance and Treatment of Premature Systoles'. Dr. William J. Dieckmann, Chicago, discussed 'Toxemias of Pregnancy, Especially the Nonconvulsive Type' as a guest of the Marion County Academy of Medicine, February 6. Drs. William E. Lower and William J. Engel, Cleveland, addressed the Mahoning County Medical Society, Youngstown, March 20, on 'Endocrine Factors in Human Economy' and 'Present Status of Intravascular Surgery', respectively. Dr. Louis Feid, Jr., Cincinnati, addressed the Ross County Medical Society, February 1, on 'Benign Uterine Hemorrhage and Its Treatment'. Dr. T. Wingate Todd, Cleveland, addressed the Cincinnati Academy of Medicine, March 5, on 'The Physiology of Youth'.

PENNSYLVANIA

Interns' Prize Contest—Dr. George C. Schein, intern at South Side Hospital, Pittsburgh, won first prize in the annual interns case report contest conducted by the Allegheny County Medical Society. Second and third prizes were won by Drs. Harry Lubow and Clyde B. Trees and honorable mention went to Drs. William N. Pitchford and George W. Hobson. All are graduates of the University of Pittsburgh College of Medicine except Dr. Trees who is a graduate of Harvard University Medical School. Dr. Schein read his paper at the meeting of the society, March 20.

Philadelphia

Society News—Drs Nathaniel W. Winkelman and Alexander Silverstein, among others, addressed the Philadelphia Neurological Society, February 23, on "Unilateral Amyotrophy—Its Diagnostic Importance for Cerebral Localization."

Hospital News—Dr Abraham I. Rubenstone, medical director of Mount Sinai Hospital, will deliver the eighth of a series of public health talks sponsored by this hospital, April 25, on diabetes. Dr Bernard Mann will speak on cancer, March 28.

Seminar on Gynecology and Obstetrics—The fourth course of seminars under the auspices of the Philadelphia County Medical Society related to gynecology and obstetrics. Following is the program:

Drs Charles Mazer and Franklin I. Payne: Our Present Knowledge of Sex Physiology and Clinical Applications of the Newer Knowledge in Female Endocrinology, respectively, March 2.

Drs Philip F. Williams and Edward A. Schumann: Toxemias of Pregnancy and Hemorrhage, respectively, March 9.

Drs Charles C. Norris and Robert A. Kimbrough Jr.: Significance of Menopausal Bleeding and Diagnosis and Treatment of Cervical Lesions, respectively, March 16.

Drs Norris W. Vaux and Edmund B. Piper: Management of Anomalies of the Passages and Puerperal Infection, respectively, March 23.

Drs Piper and Floyd E. Keene: round table conference, March 30.

RHODE ISLAND

Bills Introduced—H 736 proposes to amend the workmen's compensation act by providing compensation for disabilities resulting from certain occupational diseases named in the bill. H 738 proposes to repeal existing laws relating to narcotic drugs and to enact a uniform narcotic drug act.

SOUTH CAROLINA

Bill Introduced—S 1562 provides that no physician, surgeon, osteopath, homeopath, chiropractor, registered nurse or any other person practicing medicine or any branch thereof shall without first obtaining permission from the patient or his personal representative, be permitted to disclose any information acquired by him in attending a patient in a professional capacity.

VIRGINIA

Bill Passed—H 236, to amend the law making it now unlawful for any tobacco manufacturer to employ opium either in the tobacco used or in the paper wrappers of cigarettes by forbidding also the like use of marihuana, loco weed or any other sedative, narcotic or hypnotic drug, or like chemical or substance, has passed the house and senate.

McGuire Lectures—Dr Frank Charles Mann, professor of pathology, surgery and experimental physiology, Mayo Foundation, Rochester, Minn., will deliver the McGuire Lectures at the Medical College of Virginia, Richmond, April 2-3. His subjects will be "Anatomy and Physiology of the Liver" and "Experimental Pathology of the Liver."

Society News—The Smyth County Medical Society was organized at a meeting in Marion, February 14, with Dr Avery B. Graybeal as president. Drs Harry Goldstein and Samuel Beverly Cary, among others, addressed the Roanoke Academy of Medicine, February 5, on "Bronchial Fistula with Spontaneous Recovery" and "Problems in Transurethral Surgery," respectively.

WASHINGTON

Society News—Dr Harold Brunn, San Francisco addressed a special meeting of the King County Medical Society, Seattle, March 16, on diseases of the chest. Drs Alexander H. Peacock, Seattle, and Kenneth K. Sherwood, Kirkland, addressed the society, February 19, on "Diverticula of the Bladder" and "Vaccine Treatment of Arthritis," respectively. At a meeting of the Chelan County Medical Society, Wenatchee, January 4, speakers were Drs Edward J. Barnett, Spokane, on "Nephritis in Infancy and Childhood" and "Thrombosis of Dural Venous Sinuses in Childhood" and Donald G. Corbett, Spokane, on "Transurethral Resection of Vesical Neck Obstruction." The Kitsap County Medical Society was organized at Bremerton, January 3, with Dr Henry A. Barner, Bremerton, as president. Dr Paul W. Sweet, Centralia, addressed the Lewis County Medical Society, Chehalis, January 9, on "Rectovaginal Fistula." Dr Herbert W. E. Johnson, Everett, presented a paper on "Malignant Conditions of the Genito-Urinary Tract" before the Snohomish County Medical Society, January 2. Drs Raymond E. Watkins and Henry H. Dixon, Portland, addressed the Walla Walla Valley Medical Society, Walla Walla, January 11, on "Carcinoma of the Female Genital Organs" and "Psychoneuroses in Relationship to General Medicine," respectively.

WISCONSIN

Officers of State Board of Health—Dr Stephen Cahana, Milwaukee, was elected president of the state board of health recently to succeed Dr Gustav Windesheim, Kenosha, who had served six years. Dr Mina B. Glasier, Bloomington, was named president-elect. Drs Joseph Dean and Cornelius A. Harper, Madison, were reelected vice president and secretary, respectively.

Society News—Dr Alfred W. Adson, Rochester, Minn., addressed the Dane County Medical Society, Madison, January 9, on "Surgical Consideration of Brain Tumors" and Dr Mabel G. Masten, Madison, discussed "Spontaneous Subarachnoid Hemorrhage." Dr Francis D. Murphy, Milwaukee, addressed the Fond du Lac County Medical Society, Fond du Lac, January 10, on coronary thrombosis. Dr Fremont A. Chandler, Chicago, gave an address on "Diseases of the Lumbar and Sacro-Iliac Regions from an Orthopedic Standpoint" before the Racine County Medical Society, Racine, January 18.

GENERAL

Negro Health Week—The twentieth annual observance of Negro Health Week will be held throughout the country during the week beginning April 1, under the joint auspices of the National Negro Health Movement, the U. S. Public Health Service, state, city and county departments of health, and the national organizations interested in public health and in racial welfare. Days of the week are designated as Mobilization Day, Home Health Day, Community Sanitation Day, Special Campaign Day, Adults' Health Day, School Health Day and General Clean-Up Day. Sunday, April 8, will be Report and Follow-Up Day.

Society News—Dr Henry M. Fitzhugh, Baltimore, was installed as president of the Federation of State Medical Boards of the United States at a meeting, February 13. Dr Irvin D. Metzger, Pittsburgh, was named president-elect. Dr Roy B. Harrison, New Orleans, vice president, and Dr Walter L. Bierring, Des Moines, were reelected secretary. The annual meeting of the American Society for the Control of Cancer was held at the New York Academy of Medicine, March 2. Clarence C. Little, Sc.D., managing director, reviewed the work of the society. Dr George H. Bigelow, Boston, described the program of cancer research of the Massachusetts state department of health. Dr John C. A. Gerster, New York, work of the New York City Committee, and Dr Joseph Colt Bloodgood, Baltimore, cancer research at Johns Hopkins University.

Medal for Discovery of "Heavy Water"—The Willard Gibbs Medal has been awarded to Harold C. Urey, Ph.D., associate professor of chemistry at Columbia University since 1929, for his discovery of "heavy water." In this compound, the hydrogen atom weighs twice as much as the hydrogen in ordinary water. The Willard Gibbs Medal is annually awarded by the Chicago section of the American Chemical Society to a scientist in any country "whose work in either pure or applied science has received world wide recognition." Founded in 1911, the medal is named for Josiah Willard Gibbs, American scientist who was professor of mathematical physics at Yale from 1871 until 1903. Born in Walkerton, Ind., Dr Urey, who is 41 years old, received his early education in Indiana. In 1917 he was graduated from the University of Montana with the degree of bachelor of science in zoology, and in 1923 he received the degree of doctor of philosophy in chemistry from the University of California. He is the editor of the *Journal of Chemical Physics*.

A New Sixteen Million Dollar Foundation—About \$16,000,000 has been made available for philanthropic purposes through the recent creation of the Horace H. and Mark A. Rackham Fund in Detroit. Dr Mark S. Knapp, Flint, Mich., has been named director of medical research. He has been authorized to make a survey of possible fields of research in social sciences, character building, child welfare and health and medical research. On completing this study, which will be carried on in various research laboratories and universities throughout the country, his recommendations will be acted on by an advisory council. In addition the desirability of "establishing a scientific medical and health research institute" is to be considered. The fund was created by the late Horace H. Rackham, a Detroit attorney, who died last June. His will provided that the residue of the estate after payment of bequests should create a fund to be used for the good of humanity, and named a board of trustees to administer it. The trustees are Mrs. Mary A. Rackham, the widow, Bryson D. Horton, retired manufacturer, Judge Arthur J. Lacy and Attorney Clarence Wilcox, all of Detroit.

Medical Bills in Congress—*Changes in Status* S 2800, the Copeland bill to prevent the manufacture, shipment and sale of adulterated or misbranded food, drink, drugs and cosmetics, and to prevent the false advertisement of such commodities, has been reported to the Senate, with amendments. As reported, the section of the bill has been eliminated which was designed to discourage the advertisement of drugs for the treatment of appendicitis, cancer, epilepsy, goiter, heart diseases, poliomyelitis, venereal diseases and certain other diseases. S 2101 has passed the Senate, proposing to prohibit the mailing of unsolicited merchandise. S 2526 has been reported to the Senate, proposing to pay an annuity to Frances Agramonte, the widow of Dr Aristides Agramonte, a member of the yellow fever commission. H R 471 has been reported to the House (H Rept 931). The bill proposes to pay the Physicians and Surgeons Hospital (Limited), Glendale, Calif., for professional services rendered an enlisted man in the navy, who was injured while on leave. A claim for reimbursement for the services rendered was disallowed by the comptroller general because "enlisted men of the Navy are not entitled to medical treatment at public expense while on leave of absence or furlough." H R 5817 has been reported to the House (H Rept 941). This bill proposes to pay the Mary Black Clinic, Spartanburg, S C, for professional services rendered a seaman of the United States Navy. While serving in the United States Navy, this seaman was operated on for an abscess of the abdomen and transferred to the Naval Hospital, Norfolk, Va., for treatment. While on leave from the hospital, he was stricken with an acute attack in the abdomen, and emergency treatment was rendered by the Mary Black Clinic. The claim for reimbursement for the emergency services rendered was disallowed by the comptroller general, who held that "enlisted men of the Navy are not entitled to medical treatment at public expense while on leave of absence or furlough." *Bills Introduced* H R 8498, introduced by Delegate Dimond, Alaska, proposes to extend the facilities of the Public Health Service to seamen on government vessels not in the military or naval establishments. H R 8580, introduced by Representative Martin, Oregon, proposes to extend the benefits of the Economy Act, approved March 20, 1933, to all contract veterans who served in the foreign service under the jurisdiction of the Quartermaster General or the Surgeon General of the United States Army during the Spanish-American War, including the Philippine insurrection and the Chinese boxer rebellion. H R 8584, introduced by Representative Norton, New Jersey, proposes to furnish hospitalization and medical treatment at hospitals and relief stations of the United States Public Health Service to (a) officers of documented vessels of the United States who are holders of unexpired licenses of the United States Steamboat Inspection Service, (b) seamen who have served forty days or more on a documented vessel during the year preceding application for hospitalization or treatment, (c) seamen whose wages were diminished by reason of contributions made to the fund for the relief of sick and disabled seamen. H R 8666 introduced by Representative Mitchell, Tennessee, proposes to erect a veterans hospital in middle Tennessee.

Government Services

Annual Report of Public Health Service

In 1932, the United States achieved the lowest general death rate (10.8) in its existence, according to the sixty-second annual report of the surgeon general of the public health service for the fiscal year ended June 30, 1933. The report, which covers the one hundred and thirty-fifth year of the service, points out that, whatever influence distressing economic conditions may have had on the health of the people of the United States generally, unfavorable results are not yet apparent from an examination of crude death rates, the reports of cases of communicable diseases, or deaths of infants. The smallpox death rate for 1932 was the lowest ever recorded by the service, four deaths in each ten million of population. Forty-six states reported 10,887 cases, as compared with 28,755 cases in 1931 and 46,560 cases in 1930. Only one out of each seventeen babies died before the expiration of its first year, giving a new low rate for infant mortality. New low death rates were also reached for tuberculosis (61.3 per hundred thousand of population), diphtheria (4.8) and typhoid (4.6). Preliminary reports showed the birth rate for the year to be 17.3 births per thousand of population, indicating a continued decline. No unusual widespread epidemics occurred, and the principal

increases in the death rates were for cancer, heart disease and other so-called degenerative diseases, the death rates of which have been increasing for years. During the calendar year 1932, no case of plague occurred in the United States, but two plague-infested ground squirrels and four plague-infested rats were reported in California. In the Territory of Hawaii, six cases of plague with five deaths were reported. During 1932, 421 cases of Rocky Mountain spotted fever with seventy-six deaths were reported. Of this number, 304 cases with sixty-six deaths occurred in the Rocky Mountain and Pacific states, while 103 cases and ten deaths were reported in the Atlantic seaboard states. The greatest number of cases (100, with seventeen deaths) came from Montana. There was a decrease in the deaths (4,091) from pellagra. An increase in the prevalence of the disease was anticipated as the result of economic conditions, but this is not yet evident. For the year, 955 cases of typhus fever with fifty-three deaths were reported in the United States, of this number, Alabama, Georgia and Texas reported more than 80 per cent. Almost three times as many cases were reported in 1932 as in 1931, but some of this increase is attributed to better reporting of cases. Undulant fever was prevalent over the whole United States, with New York, Missouri and California reporting about one third of the total 1,502 cases. There were 945 cases of tularemia, with thirty-one deaths. Forty-seven states reported 386,597 cases of venereal disease, 234,647 of syphilis, 149,527 of gonorrhea and 2,423 of chancroid. A death rate of 30.1 per hundred thousand of population was reported for influenza, as compared with a previous rate of 25.8. At domestic ports, 398,574 alien passengers and 805,028 alien seamen were examined by medical officers, under the immigration laws. Of this number 13,942 passengers and 991 seamen were certified for various diseases and disabilities. The most important causes were trachoma, tuberculosis, feeble-mindedness, insanity, syphilis and gonorrhea. No quarantinable disease was imported from foreign countries into the United States or its dependencies. One vessel arrived at the New Orleans quarantine station with typhus fever, one case of smallpox developed among passengers undergoing quarantine detention at the San Francisco quarantine station, one vessel arrived at Honolulu after having had one death from cholera on board, and one vessel with two cases of cholera arrived at the port of Manila. In each instance measures were taken to prevent the introduction of these diseases into United States territory. During the year, in the administration of quarantine regulations, 10,935 vessels, 555,726 passengers and 852,536 seamen were inspected. In addition, 4,186 airplanes arrived at airports of entry in the United States from foreign ports, requiring quarantine inspection, these planes carried 25,767 persons, of this number only 2,209 airplanes, carrying 20,396 persons, of whom 2,327 were aliens, were subjected to medical examination by medical officers. The remainder entered without the required medical examination, owing to permission for arrival at airports at which medical officers are not available. Because of spasmodic outbreaks of psittacosis, concentrated efforts were directed toward the enforcement of new regulations governing the importation of parrots. Trachoma eradication activities were continued in Georgia, Tennessee, Kentucky, Missouri and Texas. The disease is still a serious problem in the mountain regions of the South Central states. Financial and technical assistance was given to twenty-eight states to aid them in demonstrating the value of properly organized local health service. Studies were carried on in rheumatic heart disease, the early manifestations of leprosy, the cultivation of the bacilli of human and rat leprosy, epidemiology of plague, psittacosis, and child hygiene. Construction was begun on the superstructure of the first U S narcotic farm, near Lexington, Ky., March 25, 1933, and, in May, title was acquired to the property selected at the site for the second, at Fort Worth. The new administration building of the service in Washington, D C, was occupied in May, 1933. The service received an appropriation of \$12,127,983.50, of this, \$10,655,131.46 was expended. This appropriation does not include an expenditure of \$4,812.42 from the Conditional Gift Fund of the National Institute of Health.

CORRECTION

Castration of Criminals—In the Berlin Letter, in THE JOURNAL, February 24, page 631, the words "sterilization" and "sterilized," lines 6 and 10, respectively, of the first paragraph on "The Castration of Criminals" should be changed to "castration" and "castrated," respectively.

Philadelphia

Society News—Drs Nathaniel W Winkelman and Alexander Silverstein, among others, addressed the Philadelphia Neurological Society, February 23, on "Unilateral Amyotrophy—Its Diagnostic Importance for Cerebral Localization"

Hospital News—Dr Abraham I Rubenstone, medical director of Mount Sinai Hospital will deliver the eighth of a series of public health talks sponsored by this hospital, April 25, on diabetes. Dr Bernard Mann will speak on cancer, March 28

Seminar on Gynecology and Obstetrics—The fourth course of seminars under the auspices of the Philadelphia County Medical Society related to gynecology and obstetrics following is the program

Drs Charles Mazer and Franklin I Payne Our Present Knowledge of Sex Physiology and Clinical Applications of the Newer Knowledge in Female Endocrinology respectively March 2

Drs Philip F Williams and Edward A Schumann Toxemias of Pregnancy and Hemorrhage respectively March 9

Drs Charles C Norris and Robert A Kimbrough Jr Significance of Menopausal Bleeding and Diagnosis and Treatment of Cervical Lesions respectively March 16

Drs Norris W Vaux and Edmund B Piper Management of Anomalies of the Passages and Puerperal Infection respectively March 23

Drs Piper and Floyd E Keene round table conference March 30

RHODE ISLAND

Bills Introduced—H 736 proposes to amend the workmen's compensation act by providing compensation for disabilities resulting from certain occupational diseases named in the bill. H 738 proposes to repeal existing laws relating to narcotic drugs and to enact a uniform narcotic drug act

SOUTH CAROLINA

Bill Introduced—S 1562 provides that no physician surgeon, osteopath, homeopath, chiropractor, registered nurse or any other person practicing medicine or any branch thereof shall, without first obtaining permission from the patient or his personal representative, be permitted to disclose any information acquired by him in attending a patient in a professional capacity

VIRGINIA

Bill Passed—H 236, to amend the law making it now unlawful for any tobacco manufacturer to employ opium either in the tobacco used or in the paper wrappers of cigarettes, by forbidding also the like use of marihuana, loco weed or any other sedative, narcotic or hypnotic drug, or like chemical or substance, has passed the house and senate

McGuire Lectures—Dr Frank Charles Mann, professor of pathology, surgery and experimental physiology, Mayo Foundation, Rochester, Minn, will deliver the McGuire Lectures at the Medical College of Virginia, Richmond, April 2-3. His subjects will be "Anatomy and Physiology of the Liver" and "Experimental Pathology of the Liver"

Society News—The Smyth County Medical Society was organized at a meeting in Marion, February 14, with Dr Avery B Graybeal as president—Drs Harry Goldstein and Samuel Beverly Cary, among others, addressed the Roanoke Academy of Medicine, February 5, on "Bronchial Fistula with Spontaneous Recovery" and "Problems in Transurethral Surgery," respectively

WASHINGTON

Society News—Dr Harold Brunn, San Francisco, addressed a special meeting of the King County Medical Society, Seattle, March 16, on diseases of the chest. Drs Alexander H Peacock, Seattle, and Kenneth K Sherwood, Kirkland, addressed the society, February 19, on "Diverticula of the Bladder" and "Vaccine Treatment of Arthritis," respectively—At a meeting of the Chelan County Medical Society, Wenatchee, January 4, speakers were Drs Edward J Barnett, Spokane, on 'Nephritis in Infancy and Childhood' and Thrombosis of Dural Venous Sinuses in Childhood" and Donald G Corbett, Spokane, on "Transurethral Resection of Vesical Neck Obstruction"—The Kitsap County Medical Society was organized at Bremerton January 3, with Dr Henry A Barner, Bremerton, as president—Dr Paul W Sweet, Centralia, addressed the Lewis County Medical Society, Chehalis, January 9, on 'Rectovaginal Fistula'—Dr Herbert W E. Johnson, Everett, presented a paper on "Malignant Conditions of the Genito-Urinary Tract" before the Snohomish County Medical Society, January 2—Drs Raymond E Watkins and Henry H Dixon, Portland, addressed the Walla Walla Valley Medical Society, Walla Walla, January 11, on "Carcinoma of the Female Genital Organs" and 'Psychoneuroses in Relationship to General Medicine, respectively

WISCONSIN

Officers of State Board of Health—Dr Stephen Cahana, Milwaukee, was elected president of the state board of health recently to succeed Dr Gustav Windesheim, Kenosha, who had served six years. Dr Mina B Glasier, Bloomington, was named president-elect, Drs Joseph Dean and Cornelius A Harper, Madison, were reelected vice president and secretary, respectively

Society News—Dr Alfred W Adson, Rochester, Minn, addressed the Dane County Medical Society, Madison, January 9 on "Surgical Consideration of Brain Tumors" and Dr Mabel G Masten, Madison, discussed "Spontaneous Subarachnoid Hemorrhage"—Dr Francis D Murphy, Milwaukee, addressed the Fond du Lac County Medical Society, Fond du Lac, January 10, on coronary thrombosis—Dr Fremont A Chandler, Chicago gave an address on "Diseases of the Lumbar and Sacro-Iliac Regions from an Orthopedic Standpoint" before the Racine County Medical Society, Racine, January 18

GENERAL

Negro Health Week—The twentieth annual observance of Negro Health Week will be held throughout the country during the week beginning April 1, under the joint auspices of the National Negro Health Movement, the U S Public Health Service, state, city and county departments of health, and the national organizations interested in public health and in racial welfare. Days of the week are designated as Mobilization Day, Home Health Day, Community Sanitation Day, Special Campaign Day, Adults' Health Day, School Health Day and General Clean-Up Day. Sunday, April 8, will be Report and Follow-Up Day

Society News—Dr Henry M Fitzhugh, Baltimore, was installed as president of the Federation of State Medical Boards of the United States at a meeting, February 13. Dr Irvin D Metzger, Pittsburgh was named president-elect, Dr Roy B Harrison, New Orleans, vice president, and Dr Walter L Bierring, Des Moines, was reelected secretary—The annual meeting of the American Society for the Control of Cancer was held at the New York Academy of Medicine, March 2. Clarence C Little, Sc D, managing director, reviewed the work of the society, Dr George H Bigelow, Boston, described the program of cancer research of the Massachusetts state department of health, Dr John C A Gerster, New York, work of the New York City Committee, and Dr Joseph Colt Blood good Baltimore, cancer research at Johns Hopkins University

Medal for Discovery of "Heavy Water"—The Willard Gibbs Medal has been awarded to Harold C Urey, Ph D, associate professor of chemistry at Columbia University since 1929, for his discovery of "heavy water." In this compound, the hydrogen atom weighs twice as much as the hydrogen in ordinary water. The Willard Gibbs Medal is annually awarded by the Chicago section of the American Chemical Society to a scientist in any country whose work in either pure or applied science has received world wide recognition. Founded in 1911, the medal is named for Josiah Willard Gibbs, American scientist, who was professor of mathematical physics at Yale from 1871 until 1903. Born in Walkerton, Ind, Dr Urey, who is 41 years old received his early education in Indiana. In 1917 he was graduated from the University of Montana with the degree of bachelor of science in zoology and in 1923 he received the degree of doctor of philosophy in chemistry from the University of California. He is the editor of the *Journal of Chemical Physics*

A New Sixteen Million Dollar Foundation—About \$16,000,000 has been made available for philanthropic purposes through the recent creation of the Horace H and Mark A Rackham Fund, in Detroit. Dr Mark S Knapp, Flint, Mich, has been named director of medical research. He has been authorized to make a survey of possible fields of research in social sciences, character building, child welfare and health and medical research. On completing this study, which will be carried on in various research laboratories and universities throughout the country, his recommendations will be acted on by an advisory council. In addition, the desirability of "establishing a scientific medical and health research institute" is to be considered. The fund was created by the late Horace H Rackham, a Detroit attorney, who died last June. His will provided that the residue of the estate after payment of bequests should create a fund to be used 'for the good of humanity and named a board of trustees to administer it. The trustees are Mrs Mary A Rackham, the widow, Bryson D Horton, retired manufacturer, Judge Arthur J Lacy and Attorney Clarence Wilcox, all of Detroit

Medical Bills in Congress—Changes in Status S 2800, the Copeland bill to prevent the manufacture, shipment and sale of adulterated or misbranded food, drink, drugs and cosmetics, and to prevent the false advertisement of such commodities, has been reported to the Senate, with amendments. As reported, the section of the bill has been eliminated which was designed to discourage the advertisement of drugs for the treatment of appendicitis, cancer, epilepsy, goiter, heart diseases, poliomyelitis, venereal diseases and certain other diseases. S 2101 has passed the Senate, proposing to prohibit the mailing of unsolicited merchandise. S 2526 has been reported to the Senate, proposing to pay an annuity to Frances Agramonte, the widow of Dr. Aristides Agramonte, a member of the yellow fever commission. H R 471 has been reported to the House (H Rept 931). The bill proposes to pay the Physicians and Surgeons Hospital (Limited), Glendale, Calif., for professional services rendered an enlisted man in the navy, who was injured while on leave. A claim for reimbursement for the services rendered was disallowed by the comptroller general because "enlisted men of the Navy are not entitled to medical treatment at public expense while on leave of absence or furlough." H R 5817 has been reported to the House (H Rept 941). This bill proposes to pay the Mary Black Clinic, Spartanburg, S C, for professional services rendered a seaman of the United States Navy. While serving in the United States Navy, this seaman was operated on for an abscess of the abdomen and transferred to the Naval Hospital, Norfolk, Va., for treatment. While on leave from the hospital, he was stricken with an acute attack in the abdomen, and emergency treatment was rendered by the Mary Black Clinic. The claim for reimbursement for the emergency services rendered was disallowed by the comptroller general, who held that "enlisted men of the Navy are not entitled to medical treatment at public expense while on leave of absence or furlough." **Bills Introduced** H R 8498, introduced by Delegate Dimond, Alaska, proposes to extend the facilities of the Public Health Service to seamen on government vessels not in the military or naval establishments. H R 8580, introduced by Representative Martin, Oregon, proposes to extend the benefits of the Economy Act approved March 20, 1933, to all contract veterans who served in the foreign service under the jurisdiction of the Quartermaster General or the Surgeon General of the United States Army during the Spanish-American War, including the Philippine insurrection and the Chinese boxer rebellion. H R 8584, introduced by Representative Norton, New Jersey, proposes to furnish hospitalization and medical treatment at hospitals and relief stations of the United States Public Health Service to (a) officers of documented vessels of the United States who are holders of unexpired licenses of the United States Steamboat Inspection Service, (b) seamen who have served forty days or more on a documented vessel during the year preceding application for hospitalization or treatment, (c) seamen whose wages were diminished by reason of contributions made to the fund for the relief of sick and disabled seamen. H R 8666 introduced by Representative Mitchell, Tennessee, proposes to erect a veterans hospital in middle Tennessee.

The Serum Treatment of Lobar Pneumonia

Following the great amount of work on the serum treatment of pneumonia in the United States, the Medical Research Council has assisted an extensive inquiry in the hospitals of this country during the last three years. This was placed under the control of the therapeutics trial committee of the council. Typing was generally done on the fresh sputum and lung puncture was rarely used. Serums of types I and II were prepared and standardized according to the Felton units current in the United States. It was given intravenously as early as possible. If the infecting pneumococcus could be typed without many hours' delay the appropriate serum was given after this had been done. Otherwise a preliminary dose of 20,000 units of each type was given and subsequent treatment adjusted to the type ultimately found. The routine injection was 20,000 units repeated every eight hours or at least twice a day. If no improvement was found after forty-eight hours treatment it was generally found useless to continue the serum. The total dosage varied from 50,000 to 120,000 units. Type II cases seemed to require a larger dosage than type I. After the fifth day it was generally felt that serum had no further useful action.

The following conclusions are drawn. Concentrated antiserum for type I pneumococcus reduced the fatality of type I cases of lobar pneumonia in persons between the ages of 20 and 40 but appeared to have little if any effect on older persons (from 40 to 60). It also seemed to reduce the average duration of the fever. Similar results were obtained when type II antiserum was used in type II lobar pneumonia. Immediate dangerous serum reactions were rarely seen, but one or two lots of a particular concentrated mixed serum did cause rigors and collapse. The benefits were not so marked as to make it desirable that all severe cases of lobar pneumonia irrespective of the type of the infecting pneumococcus, should be treated with type I and type II antiserum on the chance that they might belong to a type that is favorably influenced. Each case must be typed as soon as possible so that the appropriate serum may be used. The use of serum is not recommended except under conditions in which typing can be obtained. If accurate typing can be done in five or six hours, serum should be withheld until the type is known and the 20,000 Felton units given. But if more time is required for typing a preliminary dose of 20,000 units of both types should be given and the corresponding serum continued when the type is known. The first injection should be made slowly and cautiously into the vein, 1 cc being introduced in a minute or two and the total being injected in from ten to fifteen minutes. If an unfavorable reaction occurs, 0.5 or 1 cc 1:1,000 epinephrine hydrochloride should be injected subcutaneously.

In considering the results of serum treatment in Great Britain it is important to bear in mind that pneumonia is less serious in this country than in the United States. This point is brought out in an important paper on lobar pneumonia contributed to *Guy's Hospital Reports* by J. A. Ryle and R. L. Waterfield. They point out that whether from the conditions of housing and city life prevailing in the United States or from other causes, the incidence, mortality and epidemic tendency of pneumonia is greater than in the British Isles. The hospital figures in England and Scotland show a mortality between 10 and 20 per cent. At Guy's Hospital the mortality was 16 per cent between the ages of 13 and 75 years. The more gravely ill tend to go to the hospital. Hence the mortality in

private practice is lower—about 10 per cent. In the United States, on the other hand, the mortality at the Rockefeller Hospital was 19.5 per cent and at Bellevue 35.8. Among 422 cases of all types untreated with serum, Cecil found a mortality of nearly 36 per cent and among 429 cases treated with serum 28 per cent. Even this lower figure approaches twice the Guy's Hospital figure. Ryle and Waterfield are more restrained in their support of serum treatment than the therapeutics trial committee. They hold that, unless the method can be simplified, it must remain more suited to hospital than home conditions. For the most part it is contraindicated in children and adolescents, since the natural recovery rate is high in them. They would hesitate to employ it in any subject with known allergic tendencies, for they are doubtful whether the benefits would outweigh the ill effects. In previously healthy adults showing a good initial response and high leukocytosis, they would withhold serum. There thus remain adults giving cause for undue anxiety at an early stage and showing failure of leukocytosis, alcoholic addicts might be included. To these it would be justifiable to give an early dose of serum and to continue the treatment if the organism should be found to be of the appropriate type. The treatment is more worthy of consideration in type I than in type II infections. Expense prohibits the treatment for needy patients in their own homes and raises the difficult question whether to counsel their removal to a hospital. If the disease has passed its third day and adequate attention and nursing can be secured, they would usually prefer to keep the patient at home and forego the possible advantages of laboratory study and serum therapy.

Osteopaths Again Attempt to Obtain Registration

The osteopaths, undeterred by previous failures to obtain registration, are making another attempt. In the house of commons a member asked leave to introduce a bill to regulate the practice of osteopathy and to prescribe the qualifications of osteopathic practitioners. The object is to set up a statutory board with powers to compile a register of qualified osteopaths with a prescribed standard of professional conduct. The bill would give an osteopath the right to employ a qualified anesthetist (in other words a physician who specialized in anesthesia) without his falling under the ban of the General Medical Council. At present an anesthetist is not permitted to work for any one who is not a qualified medical practitioner. It was also stated that osteopaths did not seek inclusion in the medical profession. It was claimed that osteopaths had worked for thirty years in this country and had to their credit a large number of striking successes while failures had been due to 'quacks' practicing osteopathy. Leave was granted to bring in the bill. Opposition will come in the next stage.

Immunization Against Yellow Fever

At the Royal Society of Tropical Medicine Dr. G. W. M. Findlay pointed out that travel by air now enabled persons infected with yellow fever to reach from endemic centers well within the incubation period of the disease, many countries that harbored the vector of the virus. Some method of eradicating yellow fever was thus important. This could be achieved only by destruction of either the virus or the vector. As vast areas in Africa and South America are infected it is impossible to annihilate the mosquito vector. Therefore a method of immunization was desirable. Forty years ago, Carlos Juan Finlay suggested the possibility of immunizing, but no safe or efficient means of employing the ordinary virus of yellow fever had been found. However, in 1930 Theiler discovered that yellow fever could be transmitted to mice by intracerebral inoculation. These mice did not develop visceral lesions like those found in man but died from encephalitis. Intraperitoneal inoculation was fatal only to young mice in which the virus became localized in the central nervous system. After serial passage

the virus lost its power to produce visceral lesions in monkeys, though inoculated intracerebrally it produced encephalitis. All efforts to reconvert in monkeys and rodents the fixed neurotropic virus into a viscerotropic one failed. In this country 290 persons have been immunized by injections of neurotropic mouse fixed virus and human yellow fever immune serum. These include officials and others going to West Africa. Thirty per cent developed febrile reactions consisting of headache and aching in the limbs and back for twenty-four to forty-eight hours, with leukopenia and slight bradycardia. In only a small number was the reaction severe. Immune bodies began to appear in the blood seven or eight hours after inoculation and attained maximum in three or four weeks. After ten months they decreased but were still detectable after sixteen months and probably persist for much longer periods. So far the success of immunization has been demonstrated only among laboratory workers, among whom accidental infection with yellow fever used to be a common accident. Since the introduction of immunization, accidents have been completely absent.

The Diabetic Association

About a year ago the brilliant idea occurred to Mr H G Wells the writer, to form with others who have diabetes an association to provide much needed financial help for the diabetic clinic at King's College Hospital. He suggested to the hospital authorities that instead of appealing to the general philanthropic public they should limit their appeals to prosperous diabetic patients who had benefited by the modern treatment of the disease. The result was startlingly successful. A single letter from Mr Wells in the *Times* raised the required sum. Out of this sprang a permanent diabetic association, which, in addition to organizing the philanthropy of persons with diabetes, gave the advantage of opportunities for the exchange of opinions and experiences in new foods, remedies and treatment. Mr Wells now proposes to open the diabetic association to the poor as well as to the rich for mutual aid and assistance and to promote the advance of knowledge and the diffusion of information. If diabetic patients, physicians and nurses, particularly those specializing in diabetic work, can be persuaded to join it is proposed to ask for subscriptions, select a council and issue a quarterly journal, which will contain summaries of important research work, reviews and abstracts of new books on the disease, and discussions of the special foods and new drugs that are always forthcoming. A section would be available for correspondence between members and for answers to difficulties. Foundation members willing to subscribe \$25 are now being sought.

The Surplus of Physicians

While the surplus of physicians has again come to the fore, it is generally admitted that there is a similar overcrowding of all the liberal professions. In spite of the notices sent out by the dean of the *Faculté de médecine* to the pupils in the upper classes of the *lycées* and to their parents informing them that a medical career is becoming less and less attractive to a young man the number of medical students continues to increase. The number of physicians in France has increased in twenty years from 16,185 to 27,500 whereas the population for that period increased only 2,000,000. The cost of a medical education also has increased. It is estimated that the total cost today is about 110,000 francs (\$7,150) for the general practitioner and much more for those who hope to secure a post in the hospitals or a *faculté de médecine*. A physician does not begin to take in any money until he is past 30. For several years longer he is paying off the cost of his installa-

tion, his equipment and his library. The unequal distribution of physicians over the territory is, however, just as great a disadvantage as the surplus. The average number of inhabitants per physician varies greatly in different regions. In January 1930 many French departments had from 2,000 to 2,500 inhabitants to each physician. Only the departments of the Seine and the Garonne have fewer than 1,000 inhabitants to each physician. There is a strong contrast between the density of the population and the dearth of physicians in Bretagne and in the industrial regions of the North, the East and of the Loire, in which the medical service is to a great extent assured by physicians attached to private companies. The graduate physician opens up his practice where it best suits him. His choice, however, as Mr Roussy has brought out, is not influenced solely by economic factors—the desire to make a living—but partly by psychologic factors, such as the mode of life in a given region. But for the physician the leading of an agreeable existence in the cities is becoming a more difficult problem. The less fortunate physicians are finding less opportunity to secure permanent posts, since the social insurance act and the workmen's compensation act grant the patient free choice of physician. The *Confédération des syndicats médicaux français* has established a bureau that endeavors to direct young physicians of restricted means toward the rural districts. It seeks to make clear to them the hardships to which those are subjected who open a practice in the cities. The income tax, which may be fixed arbitrarily at 80 per cent of their annual rent, is not the least of the disadvantages. Some departments of France offer special inducements to physicians who consent to settle in their region. The confederation includes departmental "syndicates," which give young physicians suggestions as to suitable openings.

Increase of Mental Patients

In the report that he was requested to make on the hospital service rendered mental patients, Mr Chausse has called the attention of the general council of the Seine to the fact that the increase in the number of mental patients in the department continues with regularity. The increase noted between Oct. 1, 1932, and Oct. 1, 1933, was exceptional. The number of mental patients rose from 16,408 to 16,888, an increase of 480. The administration explains this difference by stating that the reason the psychopathic hospitals are overcrowded is not so much the increase in the number of internments as the reduction in the number of dismissals. If one compares the reports of the past two years (1931 and 1932) it will be seen that the number of admissions rose from 4,856 to 4,942, an increase of 86. The dismissals, on the other hand, were 2,938 in 1931 but dropped in 1932 to 2,170, a decrease of 768. This is no doubt a consequence of the present economic crisis. But there is still another cause for overcrowding mentioned by Mr Chausse namely, the diminution in the mortality of mental patients treated in the psychopathic hospitals. The difficulty of relieving the congestion in these hospitals is apparent. One remedy that has been applied, which consists in transferring to rural hospitals patients who have no relatives and who receive no visits, has become insufficient. Under these conditions the general council has been induced to accept the suggestions of the prefect of the Seine pertaining to the erection of a new psychopathic hospital at La-Queue-en-Brie, in Seine-et-Oise.

Phrenicectomy

Emile Sergent, Kourilsky and Clement Launay recently addressed the Academy of Medicine on phrenicectomy with reference to tuberculosis and to bronchial and pulmonary suppurations. They conclude that, in pulmonary tuberculosis, phrenicectomy should be reserved for cases in which therapeutic pneumothorax is not practicable. The intervention will be more effective if it is combined with sanatorium treatment.

It is always ineffective in old sclerosed lesions, in the presence of large cavities, in acute or miliary processes, and in dilations of the bronchi. In infected bronchiectasias it is without danger, and it is sometimes effective in cylindric bronchiectasia of recent origin. Phrenicectomy is contraindicated in the presence of putrid abscesses, particularly on the left side. It may be followed by a temporary amelioration in the more active foci but is most commonly ineffective. It is sometimes dangerous. On the whole, the authors favor pneumothorax, which is more effective and has fewer contraindications.

ITALY

Dec 31, 1933

Congress of Internal Medicine

The Società Italiana di medicina interna held its thirty-ninth national congress in Pavia, under the chairmanship of Prof. Adolfo Ferrata, director of the Clinica medica in that city. The congress convened simultaneously with the Congress of Surgery. The president, Prof. Edoardo Maragliano, senator, delivered the inaugural address, in which he recalled that the society was established in Pavia, forty years previously.

FOCAL INFECTIONS

The chief speakers on the first topic, "Focal Infections," were Professors Lusena and Chini of Rome. They pointed out that clinical observations and experimental pathology have led to the conclusion that chronic inflammatory conditions in any part of the organism (often in the mouth) may maintain morbid states in distant organs. Such points of origin of distant disorders are called foci of infection.

According to Rosenow and his followers the agents are generally streptococci or their toxins, which, emerging from the focus of infection, reach a particular organ and maintain there an inflammatory condition, being guided by the principle of selectivity. As regards the rheumatic types, the school of Rome, to which the speakers belong, has evidence to prove that a marked arthrophilia characterizes the micro organisms cultivated from the tonsils of these patients.

Investigations carried out at the Scuola di Roma confirm the possibility that streptococci may have such a selective tropism for the nervous system as to constitute a genuine neurotropic focus.

The relations between tonsillitis and nephritis have been confirmed. The speakers have made a contribution to the subject by studying the relations of foci of infection to the thyroid, to cutaneous diseases, to puerperal infection and to abortion, or miscarriage. The focal infection theory of appendicitis, gastroduodenal ulcer and cholecystitis is supported by many clinical observations. The most frequent focus is induced by tonsillitis. Particular importance attaches also to eye disorders, such as iritis, keratoconjunctivitis, choroiditis and optic neuritis. These are often associated with sinusitis and dental caries. The speakers established the role of the prostate in focal infections.

In the general discussion, Professor Frugoni of Rome emphasized that the problem of focal infections is essentially a clinical problem. The question of selectivity and of tropisms experimentally is quite different from the clinical question, which constitutes the true source of fact and observation.

UREMIA

The official speaker on the second topic, "Uremia," was Prof. Ferruccio Schupfer of Florence. The speaker distinguished true uremia, or hyperazotemic uremia, the syndrome of true anuria, hyperazotemia with hypochloridemia, eclampsia in nephritic patients, and angiogenic chronic pseudo-uremia. It is not correct to regard the anuric syndrome as identical with the uremic. In the former there is among other things, the sudden suppression of the renal function in kidneys that may

have been previously sound, and there is also suppression of the elimination of water.

The cases of hyperazotemia with chloropenia, which occur in non-nephritic persons, present many points of resemblance to cases of uremia. Chloropenia is often due to marked loss of sodium chloride as a result of vomiting and diarrhea. Many postoperative hyperazotemic syndromes suggest this type.

Eclampsia of nephritic patients is to be regarded as distinct from true uremia, for, in the former, the symptoms pointing to absolute insufficiency of the kidneys are absent. The cause of the convulsions is to be sought in an edema of the brain. In treating eclamptic attacks, one must seek to combat, by means of lumbar puncture and venesection, excessive intracranial pressure.

Angiogenic pseudo-uremia has no dependent relation with renal insufficiency and may occur also in non-nephritic persons. It is characterized by arterial hypertension and by arterial spasms, chiefly cerebral.

Professor D'Arbela, of the Clinica medica in Florence, considered uremic acidosis, pointing out that, in true uremia, compensated and decompensated acidosis may be encountered, whereas decompensated alkalosis is rare and is usually to be ascribed to pseudo-uremia. In uremic acidosis the speaker distinguishes a period of latency (preuremic acidosis), a period of compensation characterized by diminution of the alkali reserve of the blood but with a normal hydrogen ion concentration and a decompensation in which the hydrogen ion concentration becomes more distinctly acid. The kidneys play an important part in the pathogenesis of uremic acidosis, serving as regulatory organs of acid-base equilibrium. Determination of the degree of acidosis is of great diagnostic value. Antacid treatment gives good results only as a prophylactic measure.

Professor Volterra, of the Clinica medica in Florence, spoke on the chemical changes in the blood, the organic fluids and the tissues in true uremia. These changes affect both the organic and the inorganic constituents, among the latter, one observes chiefly an increase of sulphur, phosphorus and potassium together with a diminution of calcium. The chlorine content is variable and should be followed with great care by the attending physician as furnishing particularly a guide in establishing dietetic norms. Importance attaches to the elimination of nitrogen. More recently, attention has been called to the aromatic compounds—indican, the phenols, the amino-acids, oxacids, and urinary chromogens—which substances accumulate in the blood of uremic patients, and the changes in their percentages are aids in the diagnosis and the prognosis.

Professor Lunedi of Florence discussed the pathogenesis of eclampsia in nephritic patients and angiogenic pseudo-uremia. Of the theories proposed he gave special consideration to the angiospasm theory of Forlanini and to Volhard's theory of cerebral edema and concluded that neither of the two is completely satisfactory. A more recent interpretation is based on the essential elements of these two theories and assumes that the attack of eclamptic uremia is caused by a marked reduction in the flow of blood to the brain, due to arteriospasm. This change in the blood circulation is possibly followed by a sudden permeability of the capillary walls and then by cerebral edema.

In angiogenic pseudo-uremia the psychic manifestations should be attributed in part to arteriosclerotic lesions and in part to increased endocrine pressure. But some of the symptoms seem to find their most satisfactory interpretation in the angiospastic attacks, which, it would seem, must be regarded today as one of the fundamental factors of cerebral apoplexy occurring in these cases.

Mother and Child Day

December 24 was celebrated throughout Italy as a day devoted to the interests of the mother and the child. This is

the first year that such a day was set apart by the government, the purpose being to combat a trend toward a decline in the birth rate. Such propaganda appears necessary in view of the fact that recent statistics have shown that, as compared with 1,124,479 births in 1924, there were only 992,049 births in 1932, which denotes a decline of 132,000 births. This difference was not entirely covered by the diminution in the number of deaths, so that there was a net deficit of about 77,000. The birth rate has declined from 29 per thousand in 1924 to 23.8 per thousand in 1932.

The protection of mother and child is entrusted in Italy to a national organization, which is active in many related fields: the crusade against social diseases, and particularly with reference to their baneful effects on mother and child, systematic aid for expectant mothers and parturients, aid for the children of the tuberculous from the first days of their birth, aid and treatment for the children of syphilitics and malaria patients. To this society is entrusted also the propaganda for the education of future mothers, and the location in the rural districts of the institutions for the care and training of young children.

The Diploma for Specialists

Previous letters have contained accounts of the various phases through which the problem of establishing a diploma for specialists has passed during the deliberations of the Federation medicale belge and the Académie royale de médecine.

Professor Goovaerts recently denounced the following resolution passed by the academy: 1. The public authorities shall prohibit the use of the title of specialist by any physician who has not met the fixed requirements and shall impose on violators of the law penalties similar to those imposed for violations of the medical practice act. 2. In accordance with the legal provisions to be adopted by the public authorities, only holders of a special diploma can assume the duties of department heads in hospitals, institutes, polyclinics and dispensaries, and then, of course, only in the branches covered by the diploma. Likewise, only holders of a special diploma can be accepted by official bodies, societies or mutual associations for the practice of internal medicine, general surgery, obstetrics and gynecology, pediatrics, and other specialties to be specified.

The result of applying the provisions of this resolution Mr. Goovaerts points out, would be to divide the medical profession into a category of superphysicians who would enjoy all the higher privileges, and a group of subordinate physicians who, owing to the threat of prosecution for illegal practice, would be kept out of all official positions, as they could not be chosen as department heads in the hospitals, polyclinics or dispensaries and could not be sanctioned by official organizations, even for the practice of internal medicine. The proposition is the work of a small body of men who, though they doubtless had good intentions, failed, he said, to take full account of the ultimate consequences of the regimentation that they approved. The proposed regulations are disapproved by the majority of the specialists. As to the physicians who make up the body of the medical profession, they are so absorbed in their daily tasks that they do not always follow with attention the resolutions formulated in their behalf (but without asking their opinions) by the royal academy and the Council on Higher Instruction. These physicians should be enlightened in regard to the dangers that threaten them. If, after being duly informed they do not denounce the Draconian regulations that a small body of their confreres is endeavoring to impose on them and if they do not protest vehemently against the resolution passed by the Academy, there is cause for looking

despairingly into their future. They are ready, it would seem, for any abdication and any form of servitude.

On the other hand, the Société belge de chirurgie has approved unanimously the resolution of Professor de Beule, which affirms the need of creating a special diploma for surgeons, which, while not depriving doctors of medicine, surgery and obstetrics of the rights conferred on them by law, will serve to stress the need of graduate training for those who seek an official post as surgeon in a hospital or clinic. The technical and scientific progress of surgery demands imperatively the creation of a diploma guaranteeing that the holder has acquired a thorough knowledge of surgery by special studies and work under master surgeons. The society, after the adoption of this expression of principle, will take up the detailed study of the project approved by the Academy of Medicine. It will be recalled that the duty of respecting the acquired situations and legal rights has always been mentioned in all the discussions that have been held on this subject. At the meeting held Feb. 28, 1931, the third section passed the following resolution: "The Royal Academy of Medicine of Belgium, while respecting the integrity of the rights conferred by the diploma of doctor of medicine, surgery and obstetrics, takes account of the changes that the new social laws have brought about in the practice of medicine, and expresses the desire to see a diploma (or a certificate) for specialists created, and reserves for a later date a discussion of the methods of bringing about such a measure."

Controversy About Health Centers

A serious controversy has arisen at Brussels. The medical circles allege that the Société belge de médecine préventive et d'eugénique, in creating health centers to which are admitted (gratuitously in some communes, and on the payment of a small fee for the benefit of the society, in others) persons whom the physician feels that he has a right to regard as prospective clients, is exceeding the limits of the objective for which it was created. Dr. Malvoz, in an interview, confirms the opinion of the physicians: "Does not the clinical instruction of the faculties of medicine, which is constantly improving, render all physicians capable of taking blood pressures, of withdrawing blood for an examination of the urea and other constituents, or of examining a specimen of urine for the presence of albumin, sugar or the like? What would be left to the physician if his activities are to be restricted by taking away from him this essential task of his profession—the examination of a patient from both the preventive and the curative point of view? The practitioners did not wait for the creation of the Société de médecine préventive before giving periodic health examinations." It is certain that, in opening to the public the diagnostic centers, the Société belge de médecine préventive et d'eugénique is trespassing on the prerogatives of the physician. That must not be, for at present the situation of the physician, which is difficult at the best, will not admit of any competition on the part of social organizations.

Opening of Prince Leopold Institute of Tropical Medicine

The Prince Leopold Institute of Tropical Medicine at Antwerp was recently opened. The port of Antwerp is the logical port at which persons land who are returning home after service in Africa. It likewise affords shelter to a considerable number of sailors of all nationalities, whose health it watches over carefully. The institution, which occupies 2½ acres of land in the city of Antwerp, has placed side by side the part that is purely colonial and the various scientific departments: the bacteriologic laboratory, the chemical laboratory, the museum of hygiene, and the sanitary service. The theoretical instruction in tropical pathology is combined with the clinical

instruction There is a small hospital of fifty beds with all the modern comforts The new institute has taken over a triple function, it is a university, laboratory and hospital combined It is designed to furnish graduate instruction to physicians planning to practice in the Belgian Congo, to provide instruction for missionaries, sanitary officers and nurses who expect to serve in Africa, and, finally, to carry on scientific research

Insurance Against Occupational Diseases

Dr Glibert has published an article giving a survey of the insurance against occupational diseases in Belgium The law has rendered inestimable services and, although only four years has elapsed since the system was introduced, it has been sufficient to show the value of the methods constituting the mode of reparation

Four hundred requests for indemnification were presented to the "Fund", 357 were made the subject of medical inquiries and only a single case was taken to the courts The inquiries dealt chiefly with lead poisoning and a few rare cases of hydrargyrisms and anthrax infection, the three diseases accepted by the first Convention of Geneva on the subject and by the royal decrees in force at the time the research was begun

Iodine in Thyroids of Cattle

The thyroids of cattle in the cattle zones of Argentina (as reported by Mazzoco, Ruff and Torno) and in Uruguay (as reported by Goslino) are rich in iodine content In cows and sheep there is an average of 400 mg of iodine per hundred grams of thyroid powder, not previously deprived of the fat by ether According to Ruff the figures are slightly higher in winter (434 mg) than in spring (391 mg) and in summer (366 mg) The preceding data concern the area of the littoral of Argentina, the most important cattle area in the country In Salta province, however, the content of iodine in the thyroids is lower, specially in the areas where goiter is endemic (as reported by Mazzocco) The permanent committee of the pharmacopeia has suggested the adoption of a standard in order that all the commercial thyroid preparations may have an equal amount of thyroxine The standard would be used until there is an international method adopted

Continuous Paroxysmal Tabetic Topalgia

This syndrome was described by Sicard in 1921 The algia is fixed in one area, does not irradiate and is constant It is accompanied by a constant painful paroxysmal crisis and sometimes also is by tremors Dr Julio Diez reported recently a case in which an ample posterior radicotomy (sixth cervical to second dorsal) completely failed Diez then performed an anterolateral cordotomy, which brought about a complete disappearance of the pain He believes that in this disease there might be a radicular lesion but that the pain is caused by the medullary lesion and that the only surgical treatment for continuous paroxysmal tabetic topalgia is an anterolateral cordotomy

A Discussion on Tropical Pathology

A discussion of tropical pathology was conducted last October, at a meeting in Santiago del Estero, under the presidency of Dr S Mazza There were discussions on exanthematous typhus, and Drs Brumpt of Paris and Ventemillas of Bolivia read papers on vectors of mountain fever and its therapy, respectively Drs Mazza, Martinez and Cornejo Arias spoke on *Trypanosoma cruzi* in children and adults and Dr Mazza on *Trypanosoma cruzi* in mammals Papers were read on malaria and hemoglobinuric fever There were more than twenty papers read by Drs Hormaeche Videla Rey, Mazza,

Canal, Feijoo, Cornejo, Argañaraz and others on brucellosis Drs Langeron of Paris, Mackinnon of Montevideo, Talice, Niño, D'Accini, Canal and Feijoo spoke on mycosis

Pan-American Sanitary Conference

The date for the ninth Pan-American Sanitary Conference, which is to take place in Buenos Aires, has been postponed several times However, the members of the committee, under the direction of Dr G Araoz Alfaro, in accord with the government, have decided to have the meeting in 1934

Congress of Obstetrics and Gynecology

The second Congress of Obstetrics and Gynecology will meet in Buenos Aires in July 1934 The topics to be discussed will be tuberculosis and pregnancy, ovarian insufficiency, and conservative surgery in gynecology

University News

The "Luis Güemes" prize was awarded to Dr R. Izzo for his book "Semiotologia de la Azotemia" The Pascual Palma prize was awarded to Dr O Marottoli for his book "Estudio Ortopédico sobre la Cadera"

Drs E Beretervide, J J Puente P O Dezeo, L Figueroa, Alcorta, A Di Cio, O Prestini, E Com Molina and H Aprile have been nominated assistant professors of pediatrics, dermatology, hygiene, urology, medical clinics gynecology, prosthetic technic and dental anatomy, respectively, in the Faculty of Medicine of Buenos Aires

Deaths

The following deaths have been reported

Dr Juan B Señorans, the initiator of studies on experimental physiology in Argentina (1883-1886), formerly professor of legal medicine and toxicology at the Faculty of Medicine of Buenos Aires honorary professor of the Faculty of Medicine of Medicina of Buenos Aires, aged 74

Dr Martin Castro Escalada assistant professor of otorhino laryngology of the Faculty of Medicine of Buenos Aires, aged 52

Dr Alfredo Larguia, formerly director of the Conservatorio de vacuna antivaricela of Buenos Aires and formerly director of the Hospital de Niños of Buenos Aires

RIO DE JANEIRO

(From Our Regular Correspondent)

Dec 15, 1933

The National Conference for the Protection of Children

The first National Conference for the Protection of Children has just been held in Rio de Janeiro under the presidency of Prof Olinto de Oliveira, head of the department of children in Brazil The medical delegates of the Brazilian states, who were in session for eight days, discussed subjects related to the life of children, from every aspect For the protection of children in Brazil, the following points were considered

1 The law must eliminate the inequality of conditions of children, which is the most unjustifiable of all social inequalities, and insure when possible the necessities for health, education, rest, comfort and amusements

2 The federal constitution must insure the protection of the family of maternity and of infancy

3 The activities of the federal, state and municipal legislative bodies must be coordinated in maintaining the "code of children," which contains the fundamental principles of all Brazilian legislation on the subject

4 The law must insure (a) the protection of large families, (b) the familial vote (c) the civilian rights of women on the same footing as the political rights already established, (d)

punishment for abandoning the family and for its infection, (e) the prenuptial medical examination, (f) facilities for adoption, (g) the effective repression of criminal abortion, (h) the especial protection of illegitimate children, (i) the punishment of omissions on the part of the father or guardian with regard to the education of their children and wards, (j) the efficiency and legality of the civil legislation, (k) the exercise of the paternal power in the interest of the minor, and (l) the development of the natural aptitude of women to cope with child-bearing

5 Legislative and administrative measures should be adopted tending to restrict infant mortality and morbidity and for the moral defense of childhood

6 Institutions and services necessary for the protection of children should be organized throughout the country and their efficiency insured

7 Festive occasions should be promoted regularly, such as (a) health contests, (b) breast feeding contests, (c) selection of the best student in schools, (d) of the cleanest poorhouse, (e) prizes for good conduct, and (f) prizes for numerous, healthy children

8 In the federal, state and municipal budgets a certain percentage should be reserved to pay the expenses of the services of protection and assistance to children and of their education

Regulation of the Sexual Cycle

Dr Thales Martins recently gave an interesting lecture on regulation of the sexual cycle before the Society of Biology of São Paulo. He discussed the regulation of the activity of the sex glands by the hypophysis and of the latter by the ovary or the testicle. He described the dual action of the testicular hormones, one of which acts on the secondary sex characteristics and the other controls the activity of the hypophysis. He explained the influence of the nervous system on the sexual sphere through the intermediary of the hypophysis, which regularly discharges hormones in the blood. He discussed the migration of animals, birds and fishes and cited the work of a commission of members of the Royal Society, who concluded that the migration was actuated indirectly through the interrelation of the hypophysis and the sex glands and that it could be obtained by injection of hormones

The Annual Conferences of the Free Teachers

The free teachers of the Faculty of Medicine of the University of Rio de Janeiro have decided to give a series of annual conferences in order to make known the work done in all fields of medicine. The conferences that have already been given were attended by a large number of physicians and students. The free teachers play an important part in the medical instruction of Brazil because they are mostly young physicians full of ideals and enthusiasm who dedicate themselves to the work of instruction and attain great success, some of their lectures being superior to those given by professors. The annual conferences have awakened great interest in student circles

A Small Epidemic of Neuromyelitis

Professor Austregesilo, in the name of Drs Borges Fortes and Euridice de Magalhães, presented to the National Academy of Medicine experimental and anatomopathologic studies on neuromyelitis which they have been conducting. In a series of preparations he demonstrated the meningo-medullary changes and the lesions in the anterior parts of the lateral tracts showing atrophic and vascular changes. The nucleus ambiguus was found greatly altered. The lesions of periaxial neuritis of the sciatic nerve were evident. The recent inoculations of substances obtained from nine patients in the cornea of rabbits have resulted in experimental corneal lesions. The speaker called attention to the neurotropic virus which for about one year has produced a small epidemic of neuromyelitis

BUCHAREST

(From Our Regular Correspondent)

Rockefeller Foundation Aids Dispensary in Bucharest

Rumania, whose present territory is three times as large as it was prior to the war, has to expand its medical institutes, which are used for the purpose of teaching medical students. The first one to be enlarged is the Public Health and Hygiene institute, which will be one of the best equipped in Europe. The magnificent building, which will be ready in April or May, will shelter a modern preventive medical dispensary. The huge costs will be covered equally by the ministry of public health, the city of Bucharest and the Rockefeller foundation. The costs of upkeep will be shared likewise, but only for the first five years, thereafter the Rockefeller foundation will gradually withdraw. The preventive dispensary will imitate one of New York's institutes, which a special committee studied last summer. The new Bucharest dispensary will supply preventive medicine for an important district of the capital city but will also serve to educate the hygienists of the country

The New Minister of Health

Some years ago in Rumania, three members of the ministerial cabinet were physicians. One would expect that among these would have been the minister of health. Not at all. To the latter post a lawyer was appointed. The same thing has happened again. In the new liberal government, which constituted itself last December, the health minister is a layman, while the minister of public instruction is a physician, Dr Angheliescu. But the state secretary of the minister of health is a physician, who was a practitioner in a remote town. He was elected a member of the chamber of deputies and then appointed to state secretaryship.

Only good can be expected from the new regime, for Professor Gane, the state secretary, proved himself competent in 1926, when the new public health law was framed under his guidance.

Health Insurance in Bulgaria

According to the present law, insurance is compulsory for all those who work as employees in industry, commerce and agriculture. The administrators of the insurance are the friendly societies, which are organized according to territorial apportionment. Every society has a board of managers of nine or twelve members, of whom one third are employers and two thirds employees. Supervision over the societies is exercised by the sickness insurance council, in which the medical profession is well represented. Two thirds of the expense is paid by the employees and one third by the employers. The state pays 50 per cent of the administrative costs of the district societies. The insurance is due from the third day of sickness to the amount of 50 per cent of the wage. Medical attendance, drugs and hospital accommodations may be paid for twenty-six weeks.

Medical attendance is regulated by the state and there is the fullest free choice of physician. The societies have the right to employ contract physicians, but the members are at liberty to consult also noncontract physicians. Doctors' bills are supervised by a committee appointed by the medical association. In regard to drugs there is a list of those which may be prescribed without any restriction, there is another list containing proprietary medicines these can be ordered only with special justification of their being necessary. Drug stores have to allow a reduction of 20 per cent, but should the amount purchased from them exceed a certain sum, the reduction amounts to 25 per cent.

In legal disputes arising between physicians and the friendly societies the council makes the decisions.

Marriages

BENNIE BOOKER DALTON, Red Springs, N C, to Miss Willie Grace Covington of Mebane, at Wassaic, N Y, March 2

GREGORY GEORGE SHIELDS, Abbotsford, Wis, to Miss Blanche Knutson of Viroqua, at Milwaukee, Dec 28, 1933

JOHN PAUL TIERNEY, Boston, to Miss Mary Ellen Schlee-hauf of Cincinnati, at Covington, Ky, January 28

ANTHONY CHARLES JOSEPH HAHN to Miss Harriet A Nowack, both of Watertown, Wis, January 23

JOSHUA TAYLOR, Washington, N C, to Miss Mary Ann Jamison of Richmond, Va, Dec 27, 1933

FRITZ JOSEPH MOENNIGHOFF, Wichita, Kan, to Miss Alfreda Voge of Kansas City, recently

CARL H BENDLER to Miss Grace Imogene Campbell, both of Gary, Ind, February 3

EDGAR F FINCHER, JR, to Miss Helen Nichols, both of Atlanta, Ga, February 10

FRED CARL ENDRES, Peoria, Ill, to Miss Ida Wheeler of Yates City, recently

MAX W FLOTHOW to Mrs Myrtle Strehlow, both of Omaha, recently

Deaths

Max Ballin ⊕ Detroit, University of Berlin, Germany, 1892, formerly clinical professor of surgery, Detroit College of Medicine and Surgery, member of the American Surgical Association, fellow of the American College of Surgeons, served during the World War, surgeon to the Harper Hospital, consulting surgeon to the Children's Hospital, Woman's Hospital and the Highland Park (Mich) General Hospital, received the class two gold medal for his exhibit on parathyroidism at the annual session of the American Medical Association in New Orleans in 1932, aged 64, died, March 3, of heart block

Frederic Shephard Dennis ⊕ New York, Bellevue Hospital Medical College, New York, 1874, member and past president of the American Surgical Association, member of the Connecticut State Medical Society, fellow of the American College of Surgeons and the Royal College of Surgeons, since 1910 emeritus professor and from 1898 to 1910 professor of clinical surgery, Cornell University Medical College, professor of surgery at his alma mater from 1883 to 1898, consulting surgeon to the Bellevue, St Vincent's and Montefiore hospitals, New York, and the Litchfield County Hospital, Winsted, Conn, author of Dennis' System of Surgery, aged 83, died, March 8, of heart disease

Paul Edgar McNabb ⊕ Major, M C, U S Army, Washington, D C, University of Pennsylvania School of Medicine, Philadelphia, 1912, served during the World War, fellow of the American College of Physicians, member of the American Association of Pathologists and Bacteriologists, Tennessee State Medical Association, and the International Association of Medical Museums, curator of the Army Medical Museum, 1931-1933, at one time president of the U S Army Medical Department Research Board in Manila, P I, aged 46, died, February 24, in the Walter Reed General Hospital, of progressive hypertensive disease and cerebral hemorrhage

Harold L Van Metre ⊕ Los Angeles, State University of Iowa College of Medicine, Iowa City, 1915, associate clinical professor of surgery, University of Southern California School of Medicine, instructor in surgery at his alma mater, 1917-1919, fellow of the American College of Surgeons, on the staffs of the Hospital of the Good Samaritan, Methodist Hospital of Southern California, Los Angeles General, Hollywood Clara Barton Memorial and California hospitals, aged 45, died, January 27

Claude Percival Fryer ⊕ Maryville Mo Willamette University Medical Department, Salem, Ore, 1906, member of the Kansas Medical Society, formerly field agent of the U S Public Health Service and health officer of Brown County with headquarters at Hiawatha, Kan for many years health officer of Nodaway County Mo, aged 60, died Nov 9, 1933, of coronary thrombosis

Rolfe Eldridge Hughes, Laurens, S C University of Maryland School of Medicine, Baltimore, 1892 member and past president of the South Carolina Medical Association past president and for many years secretary of the Tri-State Medi-

cal Association of the Carolinas and Virginia, past president of the Laurens County Medical Society, aged 65, died, Dec. 2, 1933

John Joseph Farrell, Hannibal, Mo, Washington University School of Medicine, St Louis, 1901, member of the Missouri State Medical Association formerly secretary of the Marion County Medical Society, aged 54, on the staffs of the Levering Hospital and St Elizabeth's Hospital, where he died, Dec 3, 1933, of cerebral hemorrhage

Charles Bickham Ford ⊕ Seattle, Bellevue Hospital Medical College, New York, 1895, past president of the North Pacific Surgical Society, fellow of the American College of Surgeons, visiting gynecologist to the Seattle City Hospital and surgeon to the Children's Orthopedic Hospital, aged 60, died, February 20, of bronchopneumonia

Peter N K Schwenk ⊕ Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1882, member of the American Ophthalmological Society, fellow of the American College of Surgeons, for many years on the staffs of the Wills Hospital and the Pennsylvania Hospital, aged 79, died, February 17, of pneumonia

Arthur B Chandler, Montreal, Que, Canada, McGill University Faculty of Medicine, Montreal, 1906 served with the Canadian Army during the World War, head of the children's department of the Montreal General Hospital and medical director of the Child Welfare Association, aged 50, died, February 13

Frank Bell Fuson, Larned, Kan, Missouri Medical College, St Louis, 1886, member of the Kansas Medical Society and the American Psychiatric Association, formerly health supervisor for the state eleemosynary institutions, on the staff of the Larned State Hospital, aged 74, died, February 4, of nephritis

Benjamin Butler Keys ⊕ Murray Ky, Vanderbilt University School of Medicine, Nashville, Tenn, 1908, past president and secretary of the Calloway County Medical Society, member of the state board of health, part owner of the Keys-Houston Clinic Hospital, aged 53, died, January 25, of heart disease

Albert Marion Earel ⊕ Hoopeston Ill, Rush Medical College, Chicago 1891, member of the American Academy of Ophthalmology and Oto-Laryngology, aged 67 died, February 25, in the Lake View Hospital, Danville, of a basal skull fracture received when he fell through an elevator shaft

James Young McCullough ⊕ New Albany, Ind, University of Louisville (Ky) School of Medicine, 1907, past president of the Floyd County Medical Society, secretary of the county board of health, on the staff of St Edwards Hospital, aged 51, died, February 22, of hypernephroma

Claude Edward Case ⊕ Clifton Springs, N Y, University of Pennsylvania School of Medicine, Philadelphia, 1917, fellow of the American College of Physicians, on the staff of the Clifton Springs Sanatorium and Clinic, aged 40, died, January 27, in Doylestown, Pa, of lymphosarcoma

William Clifton Black, Greenville, S C, University of Maryland School of Medicine, Baltimore, 1886, member of the South Carolina Medical Association, fellow of the American College of Surgeons surgeon to the City Hospital, aged 73, died, Dec 12, 1933, of cirrhosis of the liver

Alonzo Blauvelt, New York College of Physicians and Surgeons in the City of New York, medical department of Columbia College, New York, 1876 for many years member of the city health department aged 79, died, February 20 in Maplewood, N J, of heart disease

James Dunaway McCann, Raymondville, Texas, Vanderbilt University School of Medicine, Nashville, Tenn, 1894, member of the State Medical Association of Texas, veteran of the Spanish-American War, aged 64, died, January 31, of heart disease

Godfrey Oldfield Cuppage, Moberly, Mo L R C S, Ireland, 1883, L K Q C P, Ireland, 1884, member of the Missouri State Medical Association, formerly health officer of Moberly, aged 73, died, Nov 18, 1933, of cerebral thrombosis

Zopher F Dunning ⊕ Milford, Conn, Albany (N Y) Medical College 1888 member of the Medical Society of the State of New York on the staff of the Milford Hospital, aged 69 died, February 4, of carcinoma of the prostate

John Walker Carter Jones ⊕ Newport News, Va, University of the South Medical Department, Sewanee, Tenn, 1900, on the staffs of the Riverside and Elizabeth Buxton hospitals, aged 55 died suddenly February 9 of coronary thrombosis

Donald Henry Conterman, Oneida N Y, Syracuse University College of Medicine, 1923, member of the Medical Society of the State of New York, for six years health officer of Oneida, aged 35, died, Dec 26, 1933, of pneumonia

GRANULOCYTOPENIA

To the Editor—My reason for commenting on an article in THE JOURNAL, February 17, entitled "Granulocytopenia," by Pauline Zininger, is that the two cases described may possibly be instances of leukosis (leukemia) rather than of agranulocytosis. The two conditions are frequently confused, despite what may seem at first glance obvious differences. It is becoming increasingly evident that the diagnosis of agranulocytosis, granulocytopenia and the like is being made on the basis of a very low leukocyte count without much consideration being given to the possibility that the leukopenia might not be primary but rather secondary to some such disorder as aplastic anemia, aleukemic leukosis (leukemia), generalized sarcomatosis with involvement of the bone marrow, or even sepsis. True or primary agranulocytosis is probably an intrinsic disorder of the bone marrow (metabolic in type?) in which the granulocytes either do not grow at all or do not properly mature. Only rarely is there an associated anemia or reduction in the blood platelets.

It may well be true that Dr Zininger's case 1 was an instance of primary agranulocytosis. However, when one notes that in the patient's second attack the hemoglobin and red blood cell count steadily diminished and the leukocyte count suddenly increased to 20,000 and 36,300 with the appearance in the peripheral blood of myelocytes and myeloblasts, the impression is obtained that the patient may not have had agranulocytosis but rather acute myelogenous leukemia. The fact that the high white blood cell count followed two injections of extract of gastric juice (adisin) does not prove anything, and it seems unwise to say that there was a "satisfactory response" to adisin especially since the patient at this point began to go definitely downhill and died within a month. I saw the same sort of "response" in a patient with aleukemic myelosis (aleukemic myelogenous leukemia) following the injection of liver extract, the leukocyte count rising to 250,000, and spontaneous reversions in cases of aleukemic leukosis to a high white cell count are not at all unusual.

There are other features in Dr Zininger's case 1 that seem to me typical of leukosis: (1) the necrotic lesions of the skin and subcutaneous tissues, (2) the failure of response to pent-nucleotide, (3) the progressively downhill course with a rising white count and anemia, (4) the postmortem examination of the spleen, which was moderately enlarged and which showed effacement of normal architecture and infiltration with cells which "were largely mononuclear but some showed polymorphic nuclei" and (5) the sections of the bone marrow, which showed "a very active regeneration of the marrow with many granular cells present." (No mention is made of the condition of the red cells or megakaryocytes.) Dr Zininger mentions the concept enunciated by Fitz-Hugh and Krumbhaar of "maturation arrest." I feel that this concept may be overemphasized and that several cases of acute leukosis have probably been on this account mistakenly diagnosed agranulocytosis, even though the marrow showed large numbers of myeloblasts and myelocytes. The author's case 2, in which necrotic lesions of the skin developed and the course was rapidly progressive to death, may also have been leukosis despite the low white blood cell count. I have myself been guilty of confusing acute leukosis with agranulocytosis. Recent reexamination of the bone marrow biopsy sections of case 1 in my first paper on the subject (*Am J M Sc* 181:502 [April] 1931) reveals typical myeloblastic proliferation, which at the time escaped me and others.

Most cases of 'agranulocytosis' that I see turn out to be acute aleukemic leukosis (leukemia), usually myelogenous in

type. These may be diagnosed by the progressive usually macrocytic anemia, progressive reduction in blood platelets, and leukopenia with the presence usually in the peripheral blood of myeloblasts (often diagnosed incorrectly as lymphocytes, monocytes and large mononuclear cells). I have found sternal bone marrow biopsy of prime importance in the diagnosis. Lympho-sarcoma may give almost the same picture if it metastasizes to the bone marrow, and one case of myelosarcoma (chloroleukosarcoma, chloroma) that I saw was diagnosed as agranulocytosis. Peculiarly enough, the great majority of the cases of leukosis I have seen are aleukemic. They masquerade not only as agranulocytosis but as pernicious anemia, splenic anemia, Brint's disease, aplastic anemia and purpura hemorrhagica. Aleukemic leukosis should always be considered in cases presenting obscure anemia, leukopenia and thrombocytopenic purpura.

Considerable skepticism has been aroused recently regarding the value of the pentose nucleotides in the treatment of agranulocytosis. Many physicians report failure in their cases. The majority of failures, as I have noted in a recent paper (Agranulocytosis: Report of Three Cases Treated with Nucleic Acid Derivatives, *New England J Med* 209:1054 [Nov 23] 1933) may be the consequence of incorrect diagnosis. Successful therapy in the presence of aleukemic leukosis or profound sepsis cannot be expected. Another possible reason for failure may be the occasional inefficacy of the pentose nucleotides in stimulating the maturation of the bone marrow leukocytes. In one case under observation now, treatment with pent-nucleotide caused extremely severe reactions, during which the white blood cell count fell progressively to 500. When the more simple nucleic acid derivative adenine sulphate, which was first used by Reznikoff (*J Clin Investigation* 9:381 [Dec] 1930) and which may possibly be the active principle of the pentose nucleotides, was given, no further reactions occurred and the patient showed rapid improvement.

WILLIAM DAVESHEK, M.D., Boston

REPORT OF A TOXIC MANIFESTATION DUE TO "DINITRENAL"*

To the Editor—The need for caution in the use of dinitrophenol as repeatedly suggested in recent issues of THE JOURNAL prompts me to submit the following report.

A white woman, aged 32, entered my office, February 15, complaining of violent itching of the palms of the hands of five days' duration. Her previous history was completely negative. She stated that she had had a generalized mottled eruption ten days previous to the onset of the itching. The rash had lasted three days. She further stated that about ten days before the appearance of the eruption she had begun to take two capsules of "Dinitrenal" daily on the advice of a friend who told her that she could reduce this way without dieting. At the end of a week she increased the daily dosage to four capsules, according to the instructions on the label of this proprietary product. Physical examination revealed moderate swelling of both hands. Irritation of the skin of the hands or of the trunk by scratching or rubbing elicited typical urticarial wheals. (There was no history of previous anaphylaxis.) The temperature was 99.6 F, the pulse rate 80. Examination of the urine gave negative results.

The pruritus proved extremely resistant to all forms of treatment. It was so severe that the patient was unable to sleep for almost six full days in spite of strong somnifacients. Then the pruritus gradually disappeared.

SIDNEY HIRSCH, M.D., Cedarhurst, L. I., N. Y.

* Dinitrenal is the trade name for a product marketed by the Drug Products Company of Long Island City. The label gives the contents of each capsule as: Dinitrophenol sodium gr 1½, Suprarenal desiccated gr ¼, Carbo vegetalis.

NIGHT BLINDNESS

To the Editor—Dr Holcomb's interesting communication (THE JOURNAL, March 10, p 786) mentions the fact that night blindness was known to classical medicine and yet there was, even then, the same confusion as to designation that has persisted to the present time. As shown by his quotations, both Hippocrates and Rhazes use the term "nyctalopia" to mean poor vision at night, i e, with lowered illumination. Dr Holcomb himself speaks of "nyctalopia" as appearing frequently in Russia with the lenten fasts. This term is generally used at present for "owl-sight," i e, vision in the dark, or for the vision of the dark-adapted eye. For night blindness a paraphrase is made with the term "hemeralopia," meaning (good) sight in daytime, i e, bright light, thus the "nyctalopia" in the British Black Sea Fleet during the war in the Crimea described by John Rees, quoted as hemeralopia. The logical French have discarded this term and have substituted for it "hesperanopia," meaning night-non-vision. If this or some similar term such as nyctanopia is not adopted, medical writers should at least use the present current terms correctly.

PERCY FRIDENBERG, M D, New York

DUST COVER FOR APPARATUS

To the Editor—A dust cover for apparatus, made from discarded x-ray films, was described by Dr R. H. McClellan in THE JOURNAL, Nov 4, 1933. This useful and economical protection for instruments can be made more dust tight if Duco household cement is used to fasten the seams. I have also found that it is easier to construct the covers by cementing the seams than by using the stationers' piercing paper fasteners suggested by Dr McClellan. Film cement, of course, could be used, but this is more expensive and has no advantage over the Duco cement except quicker drying. Care should be taken not to use the cement too generously, otherwise the film will be unduly softened and unworkmanlike joints produced.

DONALD A LAIRD, PH D, SC D, Hamilton, N Y

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

UNIVERSAL ALOPECIA AREATA

To the Editor—I have a patient who started to lose all the hair on his body last May and now for three months he has not had any. He has not had to shave for three months. He is a married man with two children and the only thing he complains of is that he is cold all the time and almost has a chill every time he goes outdoors. He also complains of feeling tired. He has the appearance of a man in good health. All the blood and urine tests are negative. What is best to do for him? Please omit name.

M D Illinois

ANSWER—This man has alopecia areata which has become universal. The baldness has a depressing mental effect and this may account for his tired feeling and inability to resist cold, though every effort must be made to find other constitutional conditions that can be held responsible for them. He must be told at the start that response to treatment will no doubt be slow and that he must expect to take treatment for many months or even more than a year before he sees benefit. Results can be obtained in most cases even as bad as his by long persistence.

If his basal metabolism is normal or low, thyroid gland extract can be given in appropriate dosage, which can be expected to counteract the tired feeling and chilly sensations. Hydrotherapy can be employed: hot baths followed by baths as cold as he is able to stand, the cold being increased as the patient's response increases. Salt may be added for increased stimulation. Cod liver oil, iron and strychnine may be employed as indicated. General ultraviolet ray exposures may also be used.

Locally, ultraviolet rays in strong dosage to small areas of the scalp, best with the water-cooled quartz mercury vapor arc lamp, may be used. An erythema followed by exfoliation should be obtained from each treatment, and they should follow one another as soon as exfoliation has taken place, the intensity being increased as needed. If this source of radiation is not available, chemical stimulation can be used. The simplest is the application several times a day of stronger ammonia water, which gives good results in some cases. It should be applied after washing the scalp with hot water and soap, which is a good preparation for any local application. Acetic acid is used in the same way, applied once every fourth or fifth day, depending on the strength of reaction. This and the still stronger medicaments should be applied by the physician and used only over limited areas, the stronger the application the smaller being the area. Tricresol, diluted with alcohol to 25 per cent, the strength increased as the weaker solution fails to cause sufficient response, may be used, or phenol in the same way. A solution containing equal parts of tincture of iodine, phenol and chloral hydrate may also be efficient. One medicament should be used until the scalp acquires resistance to it and then should be changed for another. Turpentine, kerosene, chrysarobin and even croton oil are recommended. The latter must be used with great caution, for it can destroy the hair follicles. Chrysarobin on the scalp often is carried to the eyes and causes severe conjunctivitis, which possibly can be avoided by applying it in collodion. With all methods, the eccentricity of the disease must be remembered. It can refuse to yield for a long time, whereupon a slight growth of hair is suddenly seen. When this occurs, local and general measures must be kept up until the hair is full grown, and the case watched for months after this. One of the most important parts of the treatment is encouragement of the patient to keep up treatment in spite of the long failure to see results.

FOREIGN PROTEIN THERAPY IN PSORIASIS

To the Editor—I have heard of the treatment of generalized psoriasis by intravenous typhoid bacterin injections as used sometimes in treating arthritis. Can you tell me how successful this is? Is there any newer or better treatment of this disease than is outlined in the textbooks? Please omit name.

M D Missouri

ANSWER—Foreign protein therapy has long been used with benefit in stubborn cases of psoriasis. It alone will not clear up the eruption but will often render the case amenable to local therapy to which it was previously resistant. The mildest form of such therapy is injection, intramuscularly, of the patient's own blood. This is extolled by some dermatologists as more effective than intravenous injection of typhoid vaccine. From 5 to 20 cc of blood is drawn from the vein and immediately injected into the gluteal muscles in the upper outer quadrant of the buttock. The treatment is given every fifth day and continued for from five to twenty times. It sometimes causes a mild febrile reaction. Other mild forms of foreign protein therapy are the intramuscular injection of sterile milk preparations and hypodermic injections of vaccines. Some authorities praise the action of vaccines made from the organisms isolated from the patient's stool, testing out the various vaccines and using for treatment those which cause a reaction in the patient's skin.

For intravenous injection, typhoid vaccine should be used because its reactions are controllable. Enough to cause a definite but not severe reaction should be given. In conjunction with this, as with the milder forms, local therapy must be used. Crude coal tar ointment and neorobin are cleaner than chrysarobin and as effective in most cases. With any local application, the mildest that will be effective should be used. A hot bath before application of the ointment is helpful. Grindon reports the clearing of psoriasis in some cases by the use of two hot sodium bicarbonate baths daily, a half pound of the soda being used to the bath and the patient remaining in the hot water for an hour each time.

The combination of ultraviolet radiation and crude coal tar ointment suggested by Goeckerman is perhaps the most popular method of treatment among dermatologists at the present time. The ointment used by him was that recommended by C J White: crude coal tar, 2 Gm, zinc oxide, 2 Gm, corn starch, 16 Gm, and sufficient petrolatum to make 32 Gm. This must be made by mixing the first two ingredients, then the last two, and then mixing the two mixtures, making a black ointment. After a hot bath at night, this is rubbed well into all the lesions. The next day before the ultraviolet ray treatment, it is largely removed with olive oil, leaving a light film on the lesions. This film is in some way activated by the irradiation so that its effect on the psoriasis is enhanced. After

the treatment the patient may take a bath and remain free from ointment until before retiring, when he applies it again, preparatory to the same program for the next day. This treatment is best given in the hospital but can be modified for ambulatory patients. If the patient cannot leave the ointment on his skin during the daytime, a thin film may be applied just before the ultraviolet treatment. Treatments are given as frequently as the circumstances of the patient permit. If spots of coal tar ointment get on the clothing, they should not be washed with soap and water but should first be wet with oil or kerosene for several hours, after which they can be washed out.

USE OF CONVALESCENT MEASLES SERUM

To the Editor—Will you please let me know the therapeutic value of intramuscular whole blood injections in the treatment of measles using the blood of a parent who has had the disease some time before I should also like to find out the technic of these injections and the amount of blood usually injected. Please omit name.

M D Ohio

ANSWER—Generally speaking, convalescent measles serum injected intramuscularly within four days after exposure will prevent measles in by far most of the cases. When the seventh day of the incubation period has passed protection is uncertain, and after the eighth day or later practically no protection results. The dosage may be summarized as follows. In a child of three years or under 5 cc of serum should be injected intramuscularly if within four days after exposure, in older children, about 2 cc more of serum should be given for each additional year, in children over 6 years of age, the dose should be at least 10 cc. If the injection is not given until the fifth day after exposure, the dose should be 10 cc for a child of 3 or under and from 15 to 20 cc for older children. If the serum of a parent or other adult is used the dose given should be larger, and if whole blood is injected the dose should be still larger. The injections are given into large muscular masses, such as those in the buttock or on the outer side of the thigh. There is no special technic except that aseptic precautions must be observed closely. If whole blood is injected the injection should be made immediately on withdrawal of the blood before coagulation takes place or else the blood must be citrated (add 1 per cent of sodium citrate).

PAINS IN BACK AND LEGS RELATED TO CANCER OR MENSTRUATION

To the Editor—A woman aged 50 had a partial thyroidectomy eight years ago. The left breast was amputated two years ago for advanced carcinoma. High voltage roentgen therapy was administered and there has been no local recurrence. There is a history of long standing pain in the back and stiffness of the legs which became acute about a year previous to her last operation and has continued at intervals to date. Since last May, when I first saw the patient she has had four attacks each lasting a week or two of excruciating pain in the back and both legs but principally in the right leg. The pain terminates suddenly and almost completely at the onset of menstruation. During these attacks rather large doses of morphine are required to give the patient relief. During the intermenstrual period sometimes lasting two or three months the patient is approximately as she has been for years. Do these marked remissions rule out metastases to the bones of the pelvis as the cause of the pain? Irrespective of the cause would you advise irradiation of the ovaries to bring about a cessation of menstruation? I have had roentgenograms taken last spring and again recently. They have been read as showing metastases to the pelvis but I cannot be absolutely convinced that the rarefied areas are not due to intestinal gas. It seems almost inconceivable to me that such complete remissions would occur if there were advanced metastases present. Please omit my name and city.

M D Kansas

ANSWER—Since the attacks of pain in the back and legs became acute about one year before the breast was amputated, there is most likely no relationship between the pain and the carcinoma in the breast. If the pain was due to metastases in the pelvic bones and the present pain is of the same character, it is certain that the bones after three years would show pronounced changes, which could be detected readily. There is surely no indication to stop the menstrual flow by radiation therapy because, according to the history, the attacks of pain cease almost entirely with the onset of menstruation. Hence the patient obtains relief at the time of the menses. Remissions do not necessarily rule out metastases to the bones of the pelvis. Judging from the history of the case, if bone metastases can be ruled out, relief from the severe pain can most likely be obtained by performing a pelvic sympathectomy. This operation, which consists of the removal of the so-called presacral nerve or superior hypogastric plexus, was recently described by J. P. Greenhill and H. E. Schmitz (*THE JOURNAL* July 1 1933 p 26).

CLIMATIC TREATMENT OF BRONCHIECTASIS

To the Editor—I would appreciate having a list of locations suitable for sending a patient with bronchiectasis. Would southwestern Texas offer such a person any relief?

M D Indiana

ANSWER—Climatic treatment of patients with bronchiectasis serves a useful purpose, however, it should not supplant other more direct measures of management which are frequently indicated. Of these the relief, if possible, of patients with infections of the upper respiratory tract, especially sinusitis, is important, together with the prompt removal of foreign bodies from the trachea and bronchi, and of organic obstructions of these structures, the recognition and treatment of pulmonary disease such as chronic bronchitis, lung abscess, pneumoconiosis and asthma, and the persistent employment of postural drainage when it is effective in removing fluid accumulations. A bronchoscopic examination is desirable in all cases. Cultures of the material obtained by way of the bronchoscope should be taken and an autogenous vaccine made and used cautiously. All general measures designed to improve the general health of the patient should be employed. Of these rest, fresh air, adequate sleep and a nourishing diet are important. Under proper conditions climatic treatment may prove of accessory value in improving the general health of the patient and may prevent or minimize recurrent infection of the upper respiratory tract. A dry climate at a moderate elevation is desirable and may be found in almost any part of southwestern Texas and also at Phoenix and Tucson, Ariz. and Taos, N. M. The mistake should not be made of sending a patient to the Southwest or to any other section of the country without first arranging with a responsible and competent physician in the locality who will assume medical responsibility for the patient.

CATECHIN IN GOITER

To the Editor—Can you tell me something about the use of a product called catechin in the treatment of exophthalmic goiter?

M D Connecticut

ANSWER—The expression "catechin" has lately been applied to a somewhat indefinite group of substances alleged to be antagonists to certain hormones in the body. According to a German report (Catechins Newly Discovered Substances in the Blood Berlin letter, *THE JOURNAL* Jan 7, 1933, p 55) the term "catechin" is derived from a Greek word signifying "to keep within bounds." The catechins are not substances that accidentally influence the action of a hormone but rather active substances whose special province, as it were, is to prevent excessive effects of hormones or to modify their action. German investigators, notably Blum of Frankfurt-on-Main, have long claimed that the blood contains substances that are antithyroidal in character. Blum believes that he has isolated such a product that is always found in the blood stream in large quantities, serving thus as a watchman for the thyroid gland, or, in other words, being a genuine "catechin." The studies have scarcely passed the earliest experimental stage.

It is unfortunate that the word "catechin" has been coined anew in the sense referred to. Gambir or pale catechin is described in the U. S. Pharmacopeia. Catechin has long been known to organic chemists as a product related to the tannins. It is a white crystalline substance of known structure the principal constituent of gambir, a tannin material found in Sumatra (Holleman, A. F. *A Text-Book of Organic Chemistry*, New York John Wiley & Sons, Inc., 1925). The structural formula of catechin is given in Meyer and Jacobson's *Lehrbuch der organischen Chemie* volume 2 part 3, page 91. When catechin is heated it becomes changed to the well known pyrocatechin.

TREATMENT OF SYPHILIS

To the Editor—I am treating a woman patient for syphilis (early secondary) and have given her seven intravenous injections of neoarsphenamine 0.6 Gm. and am planning to start giving either bismuth or mercury compounds with the eighth dose of arsenic. Which if either is the more satisfactory? If mercury what preparation and how much for each treatment and how applied? If bismuth what preparation and how much? Is biliposol a satisfactory product for this purpose? Would it be well to give more arsenic for the first course? The patient is 30 years old and weighs 110 pounds (50 Kg.). Please omit name.

M D, North Dakota

ANSWER—The dosage of neoarsphenamine 0.6 Gm., is probably too large especially for a woman weighing but 110 pounds (50 Kg.). It is to be recommended that the dose be reduced to 0.45 Gm. and that it be continued until she has received a total of ten injections. With the last injection of neoarsphenamine the first injection of bismuth should be given. For this purpose one may employ intramuscular injections of potas-

sium bismuth tartrate suspension in oil, given intramuscularly, 100 mg once a week. Or bismocymol, 100 mg, once a week. That is, of the metallic bismuth. Or the biliposol, 80 mg of metallic bismuth, once a week. These injections should be continued for a course of ten treatments. The bismuth course should then be followed by another course of ten injections of neoarsphenamine, 0.45 Gm, given once a week. Here again, at the end of this course of neoarsphenamine, a succeeding course of bismuth is to be recommended, and since this is an early case of secondary syphilis, with the disease well generalized, it probably would be well to follow it with still a third course of arsenical injections. A specimen of blood should be taken at the beginning of each course of treatment. Treatment should be continuous, with no rest periods between the courses, and it would be well to have a lumbar puncture done within six months to make sure that there is no involvement of the central nervous system. Naturally a patient that is under therapy with heavy metals like arsenic and bismuth should be watched closely for symptoms of intolerance, and the urine should be checked at each visit. Whether further therapy should be employed after the treatment outlined would depend on the serologic tests. If the Wassermann returns to a negative reaction and remains so, it is questionable whether further treatment would be needed. On the other hand, if they still continue to show a positive reaction, it would be well to follow the last course of arsenicals with perhaps a course of mercuric salicylate injections, 0.1 Gm intramuscularly once a week. Or, if the patient prefers, a course of mercury inunctions of fifty or sixty rubs. Any patient that has had treatment for syphilis, after the Wassermann reaction has become negative, and after such course of treatment has been completed, should be kept under observation and examined regularly for a period of years.

CYST OF OVARY

To the Editor—A woman aged 50, married twenty-eight years never was pregnant or seriously ill and gives a history of no operative work. Her menses began when she was 17 years old, they were never regular until she married, since then they have come on time the last flow occurring Jan 16 1934. There is no leukorrhea. The patient states that she has always felt well. About a month ago while in bed her husband put his arm round her waist and pulled her toward him suddenly and forcefully. She felt a snap in her right side over the lower edge of the liver. There was some pain, this gradually became worse and then subsided. About a week later the patient noticed that her abdomen was getting bigger and harder and that her breathing was rather labored. She is unable to lie on her right side. General examination reveals nothing abnormal save the presence of a great amount of fluid in the abdomen. The latter is hard and shiny. Examination of the urine is negative. The blood pressure is 144 systolic, 92 diastolic. The heart is normal save for a very slight and very soft systolic murmur. The lungs are absolutely normal. Am I justified in recommending that the abdomen be tapped so that a more complete and thorough examination can be made? Is it logical to suspect a malignant condition in a case in which no pain, no illness of any kind no loss of weight nor any of the elementary symptoms of a suspected malignant condition are or were manifested? I took a Wassermann test but have as yet received no reply. Kindly omit name.

M D Connecticut

ANSWER—The history is suggestive of traumatic rupture of a thin walled cyst or of a cystic mass with a thin area in one wall. The most common type of cyst in such a patient is one that arises in the ovary. The presence of free fluid in the abdomen does not necessarily indicate a malignant condition. It may represent fluid that was liberated when the cyst was ruptured and, in addition fluid that was being produced by the cells lining the cyst wall. Even if a large part of the fluid arises in the peritoneum, the cyst is not of necessity malignant, although most of these cases are malignant. On the other hand, the absence of ill health, loss of weight and pain do not rule out a malignant disease. It is far better to perform a laparotomy than to tap the abdomen, because the former procedure will reveal the true diagnosis and will enable the operator to remove any abnormality that is found. In a large proportion of women with ascites, papillomatous cysts of the ovaries are found. Even though most of these cysts are malignant and all give a malignant appearance, some are distinctly benign. Hence when papillomatous tumors of the ovaries are found a radical operation should be performed and the uterus, tubes and both ovaries should be removed. When it is technically impossible to remove all these organs, as much of the papillomatous tissue as possible should be taken out. Sometimes a cure follows such an incomplete operation. All removed tissue should of course be examined microscopically, although sometimes it is difficult to tell whether such tissue is malignant or benign. If it proves to be carcinomatous it is best to follow the operation with radiation therapy. There is a high incidence of recurrence in cases of papillary tumors of the ovaries.

CHRONIC MALARIAL SPLEEN

To the Editor—Mrs R E, a white woman about 28 years of age, a housewife became pregnant late in 1932. The family and personal history are negative except for malarial fever at intervals during 1932, the fever being present every other day during the attacks. Irregular doses of quinine were administered during the entire year. Exacerbations of malaria occurred during the entire pregnancy and were treated irregularly by another doctor. The patient consulted me in June, 1933 when she was about eight months pregnant. She was anemic in appearance and had a large, rather soft palpable mass and corresponding dullness to percussion filling most of the left side of abdomen. Fever occurred every other day. The signs were interpreted as representing an enlarged spleen due to chronic malaria. Intensive quinine therapy together with dilute hydrochloric acid and small doses of solution of potassium arsenite and in addition a tonic were instituted. About a month later the patient delivered a healthy normal infant. In spite of continued quinine therapy, arsenicals orally and intravenously (solution of potassium arsenite orally and sodium cacodylate intravenously in ascending doses, finally reaching 0.5 Gm at a dose) plasmodium bed rest and iron and ammonium citrate, the spleen remains about 4 cm inferior to the left costal margin and at times enlarges to fill half of the left side of the abdomen. For two months following delivery the patient had rather severe metrorrhagia and menorrhagia unrelieved by curettage and by calcium lactate. This was probably due to anemia (the hemoglobin was from 40 to 50 per cent) and is now much improved. The chief problems I have in mind are whether there would be any justification for splenectomy the danger of rupture of the spleen or hemorrhage into the spleen if left alone and how the patient may be helped back to better health—she still has occasional attacks of fever on alternate days. Please omit name and address.

M D, South Carolina.

ANSWER—The clinical features recorded apparently justify the classification of this case as one of chronic malarial spleen, of relatively mild degree. Malarial infections of the spleen, as seen in most of the United States, are different from those seen in countries in which malaria is prevalent. Although the spleen has been removed in a number of cases splenectomy under such circumstances indicated rather clearly that it is associated with a higher mortality than is splenectomy for any other disease. Removal of the spleen, therefore, becomes advisable only when the spleen is so large that symptoms are definitely referable to its size. As Pool and Stillman have pointed out in discussing malaria and splenomegaly, "the disease is not located exclusively in the spleen nor is that organ an incubator for the malarial parasite, therefore the removal of the chronic malarial spleen will not bring about a cure of the infection."

It would seem advisable in this case to carry out routine measures to meet such conditions as exist. Treatment for the anemia should be instituted. Quinine should be given over a sufficient length of time. If regression of the spleen does not take place, consideration should be given to irradiation of the spleen. The possibility of rupture unquestionably is greater in the malarial spleen than in any other form of splenomegaly because of the character of the enlargement, and every reasonable caution should be taken against direct or indirect injury.

EFFECTS OF INJURY ON PREGNANT WOMAN AND ON UNBORN CHILD

To the Editor—A woman aged 42, sustained an abdominal injury during the seventh month of her pregnancy. All the other children were born normal and have remained so. The mother had no miscarriages or abortions. The child was delivered at full term. Several months later this child evidenced signs of mental deficiency with lack of speech and otherwise failed to react as normal children do. Kindly let me know whether it is possible for the child to have sustained an intra uterine cerebral injury resulting in its present condition of other cases on record, and literature on the subject to which you can refer me.

LOUIS K MORGANSTEIN M D Bayonne, N J

ANSWER—While it is possible for injury during pregnancy to produce symptoms such as are described in this case, it is difficult to prove that there is a causal relationship between the injury and the child's mental retardation. Women have frequently received severe injuries to the abdomen during gestation and practically all the children born afterward have been normal. Even interruption of pregnancy by abdominal injury is uncommon and damage to the child is infrequent except in the cases of abruptio placentae and rupture of the uterus that sometimes follow trauma. The fetus lies in a sac of water, which protects it from direct injury. However, cases have been reported in the literature in which trauma to the mother was held responsible for various defects and abnormalities found in the child after birth. Most of the injuries to these children were broken bones, but in a large proportion of these cases the bony defects were not due directly to the trauma but to a predisposition to bone disturbances. Cases of intracranial hemorrhage have been ascribed to abdominal injury to the mother during pregnancy. One such case was reported by Fink (*Monatschr f Geburtsh u Gynak* 59 264 [Dec]

1922), who also mentions the case described by Seitz in which old cerebral hemorrhage was found in a child who was born alive of a woman who had had an abdominal injury. A discussion of the subject of trauma during pregnancy and its effects on the fetus may be found in the article by A. S. Hammerschlag "Trauma und Operation, bei Schwangerschaft" in Halban-Seitz's *Biologie und Pathologie des Weibes* 8 957, 1927.

It must be remembered that occasionally a woman over 40 years of age, especially one who has had a large number of children, gives birth to an abnormal child. The usual type of defect in such cases is mongolian idocy. Regardless of this, a backward child may be born to almost any type of parent. Furthermore, the child may show mental deficiency at the present time but its development may speed up later so that it will become as normal as other children.

BLOOD IN SPINAL FLUID

To the Editor—A boy aged 7 previously healthy suffered from constipation for four or five days and failed to get results from cathartics or enemas. I found the child in an extremely nervous condition with general body twitchings. Temperature and pulse were normal. There was no abdominal tenderness or rigidity. I could not elicit any peristalsis whatever. The child complained only of difficulty in swallowing and a sensation of having something in his throat which made him cough. The pupils were equal and reacted to light and in accommodation. A preliminary diagnosis of paralytic ileus was made. He became progressively worse until three hours later the pupils were contracted and did not react to light and there was slight rigidity of the neck. Other physical signs were absent. It was decided to do a spinal puncture but while the nurse was preparing the suitable needles the patient died. Immediately after death a lumbar puncture was done and with a syringe 30 cc of practically pure blood was withdrawn from the spinal canal. This was apparently under considerable pressure. Cultures did not yield any bacteria. There was no past history of an injury to cause this hemorrhage. I have not been able to find in any of the literature reports of massive hemorrhage in the spinal canal except that which is due to trauma. I am desirous of knowing what conditions might cause such massive hemorrhage other than trauma. Please omit name.

M D Pennsylvania

ANSWER—Pure blood may occur in the spinal fluid in cases of cerebral aneurysm. Necropsy in these cases discloses ruptured aneurysm of the circle of Willis. Such central lesions are usually associated with fever and occur as a rule in elderly persons. It has nevertheless been found that cerebral aneurysm may be congenital in origin or may be the sequel of an infectious embolus. Multiple cerebral emboli may result as complications of subacute bacterial endocarditis.

Blood may pour into the spinal fluid if an apoplexy has taken place, particularly if the vessel has ruptured into the lateral ventricles.

The fluid may be blood tinged in fracture of the skull if meningeal hemorrhage has occurred.

It should not be forgotten that there is a plexus of veins on the posterior wall of the body of the vertebra. If these are punctured, a bloody fluid will be obtained.

It is unfortunate that a necropsy was not obtained in this case to permit a more accurate appraisal of the condition of the organs, so as to ascertain the definite cause of death.

EFFECTS OF GLYCINE ON MYOCARDITIS

To the Editor—The feeding of glycine or glycolol (an amino acid) in the several muscular dystrophies particularly myasthenia gravis appears to be fraught with a good deal of success as manifested by the improvement in muscular tone and strength of those afflicted with these mysterious maladies of muscle nutrition. Would it not be possible to improve the nutrition of the heart muscle by such feedings of glycine in those afflicted with myocarditis? Of course the skeletal muscles are under a different kind of nervous control, probably the chemical structure of the myocardium is different from that of the skeletal groups. Is it known that the vagus has trophic functions? Are there known chemical or physiologic reasons why feeding glycine would be ineffective in myocarditis? It seems that it might be tried without jeopardizing the functions of a diseased malnourished heart.

M D Pennsylvania

ANSWER—There are no known physiologic reasons why feeding glycine should be effective in the treatment of myocarditis, especially when one considers that myocarditis is generally considered to be due to anatomic changes in the muscle itself and not secondary to pathologic or impaired function of its extrinsic nervous mechanism. Furthermore, there is no experimental evidence to show that the vagus nerves carry trophic impulses. In the experimental animal, double vagotomy does not lead to changes in the cardiac musculature as seen in skeletal muscle deprived of its efferent nerve supply.

It should be understood that the muscular dystrophies may be primarily of central origin particularly myasthenia gravis.

In some unpublished work on myasthenia gravis by Luckhardt and Johnson it was found by knee jerk experiments that following injections of ephedrine (which is a powerful central nervous system stimulant) there was a marked and progressive increase in the knee jerk and this was associated with marked clinical improvement. This bit of evidence suggests that myasthenia gravis may be primarily of central origin.

Furthermore, the heart muscle is not generally involved in the muscular dystrophy except as secondary to the general malnutrition of the body.

NAPHTHA JAG

To the Editor—I have a patient a man aged 42 who on Saturday January 20 used Clx Chromium Cleaner and Noble's Cleaner on his car for a period of two and one-half hours in a small garage with the doors shut and no ventilation. About two hours afterward he developed an unsteadiness of gait and the next morning he was unable to stand alone. Examination was negative except for apparent severe cerebellar disturbances. As long as he lay quiet and did not turn his head he felt perfectly normal except for a lightness in his head. If he tried to rise up or turn his head from side to side he immediately became very dizzy and would feel that he was falling. When he attempted to stand up and walk he could not even stagger across the room holding on to fixed objects. This condition has improved and now he can walk across the room with some assurance if he stays close to a fixed object although his gait is distinctly ataxic. There seems to be nothing else in his history that would account for this nerve involvement. He tells me that in using the cleaners he found that one of them called Clx seemed to dry too quickly and he could not rub it off so he took gasoline to remove the residue of the cleaner.

HOWARD B. GOODRICH M.D. Hannibal Mo

ANSWER—No exact information is available as to the specific content of the two cleaners mentioned. It is, however, possible to account for the condition described from a knowledge of the toxicity of gasoline. All gasoline, naphthas, Stoddard's solvent and the like are toxic and gasoline, being more readily evaporated, is more toxic than those others with higher boiling points. The acute condition produced is commonly termed a "naphtha jag." In addition to cerebellar involvement it is not unusual for higher centers to be involved. A few persons become sensitized to the action of these petroleum derivatives and thus readily respond to trivial reexposures. From the fact that this work was carried out in a small garage with no ventilation together with the fact that a large surface from which evaporation took place was provided, it is believed that a practical hazard to acute gasoline poisoning existed. The possibility of carbon monoxide poisoning should be ruled out by further inquiry. Should it still be felt that a need exists for an analysis of the two cleaners mentioned, information as to sources of such services will be provided on supplemental inquiry.

ANGIONEUROTIC EDEMA OR QUINCKE'S DISEASE

To the Editor—A woman aged 24 weighing 150 pounds (68 Kg.) married five years sterile had menorrhagia of three years duration for which she has been treated by radium curettage and glandular therapy without relief so that finally she had a hysterectomy. She has had endocrine symptoms for the last five years for which she is now on gland therapy. She now complains of frequent attacks of puffiness in the neck anteriorly and extending laterally in the supraclavicular fossa. These lateral swellings are about the size of an egg have the consistency of cotton and do not pit on pressure. There is no pulsation, crepitus or bruit. The condition comes on suddenly and may last from a day to a week during which time the patient is extremely nervous. It then disappears as suddenly as it came. I should like to know the cause and the treatment. Kindly omit name.

MD Illinois

ANSWER—The condition described is most likely that previously known as angioneurotic edema but now more frequently called transient circumscribed edema or Quincke's disease. According to Maranon this condition, which is always transient, "seems to be due to a colloidoclastic disturbance, an anaphylaxis which brings it close to urticaria." In most cases the swellings are colorless or crimson, are hard, appear in different parts of the skin, and do not pit on pressure. After a variable length of time they disappear, without leaving any traces. However, after frequent recurrences the swellings may persist. These lesions may or may not be accompanied by other manifestations. They may occur during the menstrual periods, but in most cases the important factor is a premature or physiologic ovarian insufficiency hence these local adiposities are not rare during the menopause.

In the menopause and the premenopausal period there is also a fairly frequent occurrence of the condition known as 'supraclavicular lipomas' and 'supraclavicular pseudolipomas.' These are symmetrical lipomas which deform the shoulder lines and are sometimes painful. In the latter instance they are regarded as indications of Dercum's syndrome. These painful swellings

are also more common after the menopause and castration than at other times. They often improve under ovarian therapy. However, in addition to ovarian insufficiency, other factors in this syndrome may be disturbed function of the hypophysis and thyroid as well as a nervous factor.

In the case cited it is advisable to administer such ovarian preparations as theelin and ammotin. If these substances do not give relief, it may be well to try anterior pituitary hormones.

BÖHLER SLING

To the Editor—Kindly let me know what a Bohler sling is. In an excerpt from the *American Journal of Surgery* in THE JOURNAL Nov 4 1933 page 1510 it says that utilization of the Bohler sling rendered unnecessary the use of casts skeletal traction or open operation and that the patients can be treated at home as well as at the hospital. Where can I read of it and see a diagram of it?

HENRY F. CASSIDY, M.D., Baltimore

ANSWER—The Braun-Bohler splint is illustrated in a book entitled "Treatment of Fractures," translated by M. E. Steinberg and published by Wilhelm Maudrich of Vienna in 1929. It is also illustrated in an article by A. B. Ilievitz published in the *American Journal of Surgery* (21 21 [July] 1933).

CEREBRAL ARTERY MOST FREQUENTLY INVOLVED IN CEREBRAL HEMORRHAGE

To the Editor—Please tell me which one of the arteries ruptures most commonly in cerebral hemorrhage (apoplexy) as I have read some differences of opinion on the subject.

THOMAS GAERST, Curaçao, Dutch West Indies

ANSWER—The artery from which bleeding occurs most frequently in cerebral hemorrhage is the lenticulostriate artery, which arises from the anterolateral ganglionic branches of the middle cerebral. The lenticulostriate artery was called by Charcot the artery of cerebral hemorrhage. It runs between the lenticular nucleus and the external capsule and ends in the caudate nucleus.

CHORDEE AFTER GONORRHEA

To the Editor—A man aged 38 had an attack of acute gonorrhea two years ago which cleared up under treatment in two months. Since then he has complained of impotence and chordee. Physical examination is negative. The prostate is normal, slides are normal and there are no strictures. He has received bromides and cacodylates to no avail. What treatment would you recommend? Please omit name.

M. D. Washington

ANSWER—Chordee persisting so long after an acute attack is due either to a submucous infiltration or to some damage to one or more cavernous sinuses. Dilatation with large sounds may improve this. Medical diathermy may also be tried. The impotence is in all probability a temporary condition.

NUMBNESS OF ARM AND HAND

To the Editor—In Queries and Minor Notes (THE JOURNAL February 3 p 395) a physician of Washington asks for an idea as to diagnosis for numbness of the left arm and hand. The brachial plexus and nerves derived from it especially the musculospiral nerve are liable to injury incident to their situation. The great mobility of the bones of the arm and shoulder permits a number of extreme postures which are capable of causing great injury to the nerves. A great many cases of brachial neuritis could be prevented if the possibility of their occurrence were generally known. One of the common and easily avoidable causes seen nowadays is the faulty position of the left arm in automobile driving. The left arm is raised, with the elbow resting on the open window of the door whereby not only is the arm subject to the wind and draft but the uplifted arm stretches the plexus setting up a neuritis of the musculospiral nerve. Or the shoulder joint from fatigue and relaxation of the muscles that normally held it backward and upward sags downward and forward and the head of the humerus may compress the ulnar nerve against the second rib causing a true pressure neuritis. In thin persons the ulnar nerve alone may be affected but in stouter patients a padding of fat may transmit the pressure to the whole plexus. I have not seen this particular form of neuritis described in the literature or in text books. As good a term as any would be driver's arm.

R. DE R. BARONDES, M.D., San Francisco

TREATMENT OF VINCENT'S INFECTION OF THE MOUTH

To the Editor—On page 639 of the February 24 issue of THE JOURNAL you have presented an answer to an inquiry on Vincent's infection of the mouth which seems to me to be the most sane exposition on the treatment of this acute condition that I have seen. I am especially impressed with your last paragraph in regard to the uncalculated and incidentally dangerous treatment of this disease with organic chemicals which I have strongly opposed ever since these chemicals were recommended for this purpose i. e. about 1919.

HERMANN PRINZ, D.D.S., M.D., Philadelphia

New York September Examination

Mr Herbert J Hamilton, chief, Professional Examinations Bureau, reports the written examination held by the Board of Medical Examiners of the State of New York at Albany, Buffalo, New York and Syracuse, Sept 25-28, 1933. The examination covered 9 subjects. An average of 75 per cent was required to pass. Two hundred and six candidates were examined, 156 of whom passed and 50 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
College of Medical Evangelists	(1932)	(1932)	1
Yale University School of Medicine	(1930) (1931)	(1931)	2
George Washington Univ School of Med	(1932 2) (1933 4)	(1933 4)	6
Georgetown Univ School of Med	(1928) (1932 2) (1933 5)	(1933 5)	8

Book Notices

Food Products. By Henry C. Sherman, Ph.D., Sc.D., Mitchell Professor of Chemistry, Columbia University. Third edition. Cloth. Price \$3. Pp. 671 with 42 illustrations. New York: Macmillan Company, 1933.

This edition constitutes a complete rewriting of this well known book, furnishing subject matter for a broad general study of foods and the chief types of food products. The first and second chapters treat of the principal constituents and functions of foods and of the general aspects of food control. Chapters on each of the chief types of food follow. The last chapter treats of the best use of foods from the standpoint of nutrition and food economics. The production, preparation for market, statistical data, storage methods, questions of sanitation, inspection and standards of purity, general composition, mineral and vitamin content, digestibility, nutritive value and place in the diet are considered for each type of food. Lists of suggested readings are appended to each chapter. The appendix includes the Food and Drugs Act, excerpts from rules and regulations for its enforcement, the meat inspection law, excerpts from meat inspection regulations, and tables on the mineral elements and vitamins of foods. The book is of particular value to all interested in foods along chemical, economic, nutritional, sanitary or technological lines.

Report on an Investigation into the Causes of Maternal Mortality in the City of Madras. Being a Report on the Investigation of 436 Maternal Deaths That Occurred During a Twelve Month Period in the City of Madras. By A. L. Mudaliyar, M.D., F.C.O.G., Second Obstetric Physician and Gynecologist, Government Hospital for Women and Children, Madras. Paper. Price 12 annas. Pp. 78. Madras: Government Press, 1933.

From a study of 26,207 births, including stillbirths, in Madras for parts of the years 1930 and 1931, twelve months in all, it was learned that there were 293 deaths from childbirth, a rate of 166 per thousand births. As stillbirths are included these figures are not comparable with others, because the latter count only live births. The author admits that "the position with regard to mortality statistics" in the whole country "is beyond all hope of assessment." As usual, sepsis caused most of the deaths, 264 per cent, anemia caused 115 per cent and was a complication in many deaths from other causes, puerperal hemorrhages caused 127 per cent, and eclampsia and toxemias only 96 per cent of the deaths. In Madras there are five maternity institutions all doing good work. The infections occurring are ascribed to overcrowding. A review of the midwife situation, stressing its educational aspect, and a large roster of recommendations complete the interesting and instructive pamphlet. Prominent among the latter is the demand for a separate provision for septic cases and separate wards for clean and suspected cases and also for all abortions.

A City Set on a Hill. The Significance of the Health Demonstration at Syracuse, New York. By C. F. A. Winslow, Dr. P.H., Professor of Public Health, Yale School of Medicine. Published for the Milbank Memorial Fund. Cloth. Price \$3. Pp. 367. Garden City: Doubleday, Doran & Company, Inc., 1934.

This is a history of the development of the city of Syracuse from its beginning down to the present day, with particular emphasis on development of health service in that city. As far as the present health service in Syracuse is concerned, the book represents an appraisal of health activities in 1931, according to the appraisal form for municipal health work developed by the Committee on Administrative Practice of the American Public Health Association. The author is also chairman of this committee. The appraisal form is recognized as a useful instrument for measuring public health work, but it has, in common with all agents of any considerable potency, certain disadvantages which are fully recognized by its sponsors. It measures quantitative values in public health work. There is as yet no objective measure of quality in public health work. Published for the Milbank Memorial Fund, this volume naturally reflects the philosophy of that organization, which tends toward socialization of medical services and emphasis on governmental responsibility for health. The book is an able exposition of this philosophy. It is naturally to be expected that a demonstration under such sponsorship would proceed largely in disregard of the possibilities for cooperative relationships with the medical profession. The author records in a number

of instances cordial cooperation of the profession with the demonstration, but he also records the failure of diphtheria immunization when for one year it was turned over to the profession. This failure, as experience elsewhere shows, is evidence of a failure of cooperation. The Milbank Fund spent approximately three fourths of a million dollars in eight years demonstrating health administration to the citizens of Syracuse. Naturally, the expenditure of such sums brought large developments, many of which are admirable. The most serious objection to this demonstration, as to others, is that it has not visualized the opportunities for drawing into public health work the vast potential resources inherent in the medical practitioners in any community, this despite the fact that on page 204 the author says "a direct and tangible result of the public health program in its broad sense must always include the practice of medicine and cooperation of an educated public as essential elements."

Die Psychoanalyse und der praktische Arzt Von Dorian Feigenbaum. Vortrag gehalten zu Ehren von Prof. Sigm. Freuds 75 Geburtstag in der Deutschen Medizinischen Gesellschaft der Stadt New York am 4. Mai 1931. Sonderdruck aus Zentralblatt für Psychotherapie und ihre Grenzgebiete. Band VI. Heft 1. Boards. Pp. 27. Leipzig: Verlag von S. Hirzel.

This is the text of an address given by Dr. Feigenbaum before the German Medical Society of New York in honor of Freud's seventy-fifth birthday. The first part summarizes in condensed form the scientific principles on which psychoanalytic therapy is based. This serves as a necessary introduction for the real theme of the address—the value of an orientation in psychoanalytic principles on the part of the general practitioner and of physicians in other branches of medicine. This is illustrated by means of two cases, which are interestingly and briefly presented. One of these illustrates the futility and danger of a "rest cure" without understanding or even investigation of the patient's psychologic situation. This is contrasted with the prompt help that psychoanalysis was able to bring in a favorable case. The address concludes with a brief discussion of some of the limitations of the field in which psychoanalytic therapy is indicated.

A Guide for Developing Psychiatric Social Work in State Hospitals By Hester B. Crutcher, Director of Social Work, Department of Mental Hygiene, State of New York. With a foreword by Frederick W. Parsons. M.D. Paper. Price 50 cents. Pp. 57. Utica, New York: State Hospitals Press, 1933.

This monograph outlines the functions of psychiatric social workers in state hospitals. The qualifications, training and personality needed for this work are presented, and the importance of understanding the environment is stressed. Under the plan laid out, the social worker is an active agent in the actual treatment of patients and not, as is often the case, merely concerned with routine questions and answers. Enlightening and practical procedures are suggested in the later chapters. Several excellent outlines are presented for taking histories, pre-parole summaries, boarding home investigations, social analysis from the point of view of treatment, and monthly reports. It is wisely stressed that history forms must not be followed blindly, as informants will often bring up spontaneously much that would be missed by the routine question and answer method. The monograph does not so much give definite directions as to what should be done as suggest the lines that should be followed; it gives the psychiatrist an excellent idea of the services that can be rendered by social workers.

Abhandlungen aus dem Gesamtgebiete der Hygiene. Herausgegeben von Dr. R. Grassberger, o. ö. Professor der Hygiene, Leiter des Hygienischen Institutes der Universität in Wien. Heft 14. Das Verhalten von Bluthörperchen sowie von Mikroben in abgestuften Essigsäure-NaVanadatgemischen. Eine biochemische Methode zum Studium der Artsppezifität. Von Dr. H. M. Jettmar, Assistent am Hygienischen Institut der Universität in Wien. Paper. Pp. 121 with 19 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1934.

When serum is added to mixtures of various proportions of acetic acid and sodium vanadate, different forms of precipitation result. Herein lies the principle of Benden's "lability reaction." Jettmar describes the effects on the blood corpuscles of various species by acetic acid and sodium vanadate mixtures, also the effects of such mixtures on micro-organisms in suspension. The results are of interest to students of chemococcolloid reactions in general.

Metabolic Diseases and Their Treatment. By Dr. Erich Grafe, Professor of Medicine and Director of the Clinic of Medicine and Neurology at the University of Würzburg, Germany. Translated by Margaret Galt Bolse under the supervision of Eugene F. Du Bois, M.D., Medical Director, Russell Sage Institute of Pathology, and Henry B. Richardson, M.D., Associate Professor of Medicine, Cornell University Medical College, New York. Cloth. Price \$6.50. Pp. 551 with 37 illustrations. Philadelphia: Lea & Febiger, 1933.

This volume, competently translated, has been revised and brought down to date since it appeared in German, about two years ago. Although it was primarily intended as a practical handbook for the physician and student, its chief interest for the American reader will probably depend on the mature, moderate and concise discussion of the experimental and theoretical considerations involved in the etiology and treatment of the metabolic diseases. The bibliography is rather extensive and is conveniently placed in footnote form on the pages where it is cited. Although German references predominate, the significant American literature is also represented. The subject matter is divided into five main parts: 1. General remarks concerning metabolism and nutrition (29 pages). 2. Nature and treatment of nutritional disorders (78 pages). 3. Metabolic diseases and their treatment (282 pages). This, the major section, is divided into three chapters, on obesity, habitual undernutrition (magersucht) and diabetes mellitus (202 pages). 4. Qualitative disturbances of protein metabolism and their treatment (77 pages), these include gout, alcaptonuria, cystinuria and aminuria. 5. Disturbances of the water and mineral economy (36 pages). The author is conservative in his therapeutic advice. The book is well put together and is sufficiently well illustrated with tables and graphs. Photographs of a few patients have been reproduced.

Einführung in Geist und Studium der Medizin. Zwölf Vorlesungen von Dr. med. Georg B. Gruber, Professor der Pathologie an der Universität Göttingen. Boards. Price 4.80 marks. Pp. 271 with one illustration. Leipzig: Georg Thieme, 1934.

This book on the spirit and study of medicine is intended for beginning medical students. Its aim is to give such students a bird's-eye view of the whole field of medicine and to emphasize the point of view that medicine is an "indivisible whole." It consists of twelve lectures, which trace the development of the fundamental medical sciences and the various medical specialties and point out their relationships to the study of medicine and to medical practice. The author devotes a good portion of each lecture to giving advice to the young medical student. In spite of the fact that these lectures serve as an interesting introduction to medical history, their general paternalistic tone, though perhaps necessary for the stimulation of beginning students, may be found amusing or irritating by more mature readers.

Safety in Physical Education in Secondary Schools. By Frank S. Lloyd, Associate Professor of Education, New York University. Publications of the National Bureau of Casualty and Surety Underwriters Educational Series, Volume IX. Paper. Price \$1.25. Pp. 167. New York: National Bureau of Casualty and Surety Underwriters, 1933.

This is a careful statistical study of accidents in connection with physical education in secondary schools. As might be expected, football ranks high among causes of injury but, surprisingly enough, the gymnasium seems to be a more hazardous locality than the gridiron. Wrestling is high in injuries, while boxing is not. Among other very hazardous activities, in the order of importance, are touch football, heavy apparatus and football, while lacrosse, wrestling and tumbling are classified as highly hazardous. Ice hockey, archery, basketball, speed ball, field hockey and fencing are classed as hazardous, while pass ball, field and track, soccer, cross country and swimming are designated slightly hazardous. Minimum hazards are to be anticipated in handball, golf, indoor ball, dancing, boxing, volleyball, tennis and calisthenics, in the order named. The accident incidence per thousand participating individuals appears to bear no direct relation to days lost, although in general the very hazardous, highly hazardous, hazardous, mildly hazardous, and minimum hazard sports are grouped more or less alike, with respect both to accident incidence and to days lost. This is a publication which is indispensable to directors of physical education, coaches and athletic officials, not only for its statistical studies but also for its constructive recommendations. Those physicians who have to do with school work and athletic activities will also find it valuable.

Developing Attitudes in Children Proceedings of the Mid West Conference of the Chicago Association for Child Study and Parent Education March 1932. Cloth Price \$1.50 Pp 156 with illustrations Chicago, University of Chicago Press 1933

This book contains three main papers and six round-table discussions concerning the development of various attitudes in children, such as ethical, vocational and religious. As is frequently the case when a number of addresses are collected, it is found that there is no coherence in the group. Often, oratory is more important than facts, as in this book. Here, too, occasional conclusions are presented, but facts that support them are not given. The book, in general, tends to indicate that children accept the attitude of their parents and teachers and accept the views of those on whom they are dependent. It should not require a book of this length to reach that conclusion.

Précis de microscopie. Technique expérimentation diagnostique. Par le Dr. M. Langeron, chef de laboratoire à la Faculté de médecine de Paris. Fifth edition. Cloth Price 100 francs Pp 120 with 36 illustrations. Paris: Masson & Cie 1934

The present edition of this textbook on microscopic procedures is a worthy member of the medical series which the publishers have sponsored. It is completely rewritten and has many new chapters. The changes have been so numerous that it is almost a new book. Recent advances in the various types of microscopic illumination, micromanipulation and microchemistry are some of its features. The text is concise, and useless detail has been omitted. When supplementary information might be desirable, the author gives bibliographic references. The list, however, is not sufficiently inclusive for the amount of material covered. The organization of the book is excellent and is well adapted for the novice in the study of microscopy, as well as for those desiring a reference work on microscopic procedures beyond the scope of the average textbook. There are three main sections. The first deals with the microscope and its accessories. This is a concise and comprehensive discussion and should satisfy the needs of most students of microscopy. The second section deals with general microscopic methods and the technique of the various ways of preparing material for microscopic study. There is an ample discussion of vital staining and cytologic technique, with due consideration of the current theories and the most recent procedures. The third section deals with special methods for the microscopic investigation of protozoa, metazoa and bacteria. The value of the book would have been decidedly enhanced by a more adequate illustration of the second and third sections. For the most part this is not a standardized book on laboratory procedures as many of the methods are new and have not been thoroughly tried. The volume is, however, a definite contribution as a concise reference book or as a textbook for students of microscopy.

The Practice of Surgery By Russell Howard CBF MS FRCS Surgeon London Hospital and Alan Perry MS FRCS Surgeon London Hospital. Fourth edition. Cloth Price \$10 Pp 1388 with 592 illustrations. Baltimore: William Wood & Company 1933

This textbook serves as a good outline of general surgery as planned for students. Many features are somewhat unusual, especially the emphasis placed on diagnosis and treatment. The organization is similar to that of most textbooks of similar character. The subject matter is gradually and continuously developed from the presentation of basic pathologic and immunologic principles. The authors are to be commended for their inclusive discussion of traumatic surgery.

Die Embolie Von Dr. Sigurd Frey Privatdozent für Chirurgie an der Universität Königsberg/Pr. Boards. Price 12 marks Pp 178 with 52 illustrations. Leipzig: Georg Thieme 1933

This monograph, written by a surgeon, naturally treats the subject from a surgical point of view. Emboli located in organs where they may be treated surgically are fully discussed. Non-surgical emboli, such as those in the kidney, brain, heart and spleen, are given scanty consideration. So also are the emboli due to bacteria, parasites, pigment, tumor cells or foreign bodies. The causes of thrombosis and the structure of thrombi are fully discussed as are the clinical features and the results of thrombotic emboli on the lung, extremities and intestine. The surgical treatment of each of these accidents is set forth with

clear description and suitable illustrations. The subject of air embolism is given forty-five pages. Fat embolism also is fully treated. There is an extensive bibliography filling about twenty-five pages, according to a rough estimate, more than 90 per cent of the references are to German literature and less than 10 per cent to the literature of the rest of the world.

Text Book of Pathology By Robert Muir M.A. M.D. Sc.D. Professor of Pathology University of Glasgow. Third edition. Cloth Price \$10 1p 957 with 516 illustrations. Baltimore: William Wood & Company 1933

The first edition of this book appeared in 1924. The present edition includes recent advances and has many new illustrations as well as a new index. The book presents general pathology in chapters on disturbances of nutrition and circulation, on inflammation and on tumors. The rest of the book deals mainly with the special pathologic anatomy of the circulatory, respiratory, hematopoietic, alimentary, urinary, nervous, locomotive and reproductive systems. The last chapter is devoted to the endocrine glands. The skin, the eye and the ear are not considered. Within its field Muir's work may be regarded as a standard textbook, with special emphasis on the morphologic changes produced by disease.

The Pharmaceutical Pocket Book for Practitioners and Students Published by the Pharmaceutical Society of Great Britain. Twelfth edition. Fabrikoid. Price 5/6d 1p 344. London: Pharmaceutical Press 1933

This is published with the idea of epitomizing in convenient form the science and art of prescribing. It also contains for those who are not physicians a number of tables dealing with sources of drugs, directions for making a herbarium, and chapters on bacteriology and even on food and diet. As would be expected from this type of book, it is of service to those who are interested in drug therapy without being interested in the best interests of scientific medicine. For instance, a complex description is given for preparing an emulsion of petroleum. Pharmaceutically it is well worth reading, but medically it reflects prescribing of twenty-five years or more ago. The typographic setup of the book is excellent and could well be emulated by American authors of similar treatises.

A Reference Hand Book of Gynecology for Nurses By Catharine MacFarlane M.D. F.A.C.S. Professor of Gynecology Woman's Medical College of Pennsylvania. Sixth edition. Cloth Price \$1.50. Pp 175 with 19 illustrations. Philadelphia & London: W. B. Saunders Company 1934

This book has passed through six editions since its first appearance in 1908 when it was evolved from the author's lecture notes in gynecology. It has always maintained a high standard of accuracy and is marked for its brevity and illustrations. The trained nurse may by its use refresh her memory or revise her ideas concerning present day practice and procedure with but small effort. The new material added to the present edition is well chosen and concisely stated. Only on minor points can one take issue with the author, such as concerning the site of fertilization of the ovum (p. 26) and the viability of the unfertilized ovum (p. 28). As a whole, the book can be highly recommended to the nurse, for whom it is intended and for whom it was prepared.

Die Spezifität der serologischen Reaktionen Von Dr. K. Landsteiner the Rockefeller Institute for Medical Research New York. Paper. Price 8.80 marks. Pp 123. Berlin: Julius Springer 1933

The purpose of this monograph is to summarize the results of the work of the author and his co-workers on antigens and to discuss serologic specificity and related questions. As would be expected from the leader in the chemical study of specificity, attention centers mainly on chemical work bearing on fundamental problems. The presentation follows essentially the development of this work. There is an introductory statement of the concept of specificity, which is followed by sections on the serologic specificity of proteins on the specificity of cellular antigens on the specificity of the antibodies, on serologic reactions with artificial antigenic complexes and simple chemical substances and on chemical investigations of specific cell substances (carbohydrates, lipoids). The author is a master of clear, concise, correct statement. His method of reviewing published work is a model of exactness and concrete precision. Not a word is wasted. Landsteiner's monograph is a classic contribution. It should be translated into English.

Medicolegal

Medical Practice Acts Internal Curative Medicine, Use by Osteopath Unlawful—The defendant, a licensed osteopath, treated a patient for hemorrhoids by the interstitial infiltration method, using a solution of 95 per cent Wesson oil with 5 per cent phenol. The state of Iowa, contending that this constituted the practice of medicine, sought to enjoin him. The trial court denied the injunction and the state appealed to the Supreme Court of Iowa.

A license to practice osteopathy or osteopathy and surgery, said the Supreme Court, does not authorize the holder to prescribe or give internal curative medicine. If the defendant prescribed or gave internal curative medicines, the injunction prayed for by the state should have been granted. The defendant, while admitting that phenol is a common drug, insisted that it was not a curative medicine. Several osteopathic witnesses testified that phenol is not a curative medicine and that, as the defendant had administered it, he had not administered an internal medicine. But, said the Supreme Court, the statements of these osteopathic witnesses were evidently influenced by the theory of osteopathy, which does not believe in curing patients by the use of curative medicines. Moreover, the opinion of the witnesses with respect to curative medicines is ordinarily of lesser value than the opinion of a nonsectarian practitioner. Four nonsectarian physicians testified that phenol is an internal curative medicine and that the use of it by the defendant was the administering of medicine internally. As a matter of fact, continued the court, the defendant's own testimony shows that he used phenol internally. It is true that he did not administer it through the patient's mouth, but in modern practice internal curative medicine is frequently administered, not through the mouth, but into another part of the body by the use of the hypodermic needle or by some other process. According to the defendant's own testimony, he administered the phenol internally to set up counterirritation in the system near the hemorrhoid which he was treating. In other words he desired the counterirritant in the treatment, in addition to the ordinary manipulations of an osteopath. As thus administered, the phenol was an internal curative medicine. As was said in *State v Stoddard* (Iowa), 245 N W 273.

Internal curative medicine is some substance or preparation administered internally for the cure, removal or healing of some disease or condition demanding medical treatment.

Clearly, then, said the Supreme Court, by thus administering the phenol, the defendant gave internal curative medicine to his patient. He departed from the boundaries of osteopathy into the field of the practice of medicine and under no circumstances does his license to practice osteopathy entitle him so to do. In so practicing he violated the medical practice act and hence may be restrained by permanent injunction.

For the reasons stated above, the Supreme Court ordered that an injunction be issued, enjoining the defendant from practicing medicine.—*State v McPheeters* (Iowa), 249 N W 349.

Malpractice Fragments of Turbinate Bone Lost in Respiratory Tract—On March 29, 1930, the defendant performed a turbinectomy on the plaintiff. She, in this action against the defendant, claimed that two pieces of turbinate bone were negligently permitted by the defendant to fall down her throat and lodge in her bronchial tubes or lungs. As a result of this negligence it was contended, she became severely ill and developed acute tuberculosis. The jury returned a verdict for the plaintiff and the defendant appealed to the Supreme Court of South Dakota.

The situation in this instance said the Supreme Court is similar to cases in which surgeons leave instruments, sponges and other foreign articles inside a patient. The physician's negligence in performing the operation was submitted to the jury under appropriate instructions and the acts of the physician in severing the turbinates, the caution and care he used in performing his work and the care and skill he used to

prevent the turbinates from falling into the patient's throat and ultimately being inhaled into her lungs were all questions for the jury. The doctrine of nonliability because of error of judgment, continued the court, is not applicable here, for the reason that the defendant made no attempt in his defense to bring himself within that rule. He stood squarely on the contention that no turbinate bones were lost and that no such bones ever reached the plaintiff's lungs. He simply contended that nothing happened. Had he contended that he exercised his best judgment and gave careful attention to what he was doing, then it would be conceded that he would not have been liable for a mere error of judgment. The defendant complained that the trial court did not instruct the jury that the negligence in the case, if any, would have to be established through the testimony of experts. We do not consider, said the Supreme Court, that in this case such an instruction was warranted. Both experts and nonexperts testified in the case and the jury had the right to take into consideration all of this evidence and all of the facts and circumstances, and was not limited to the naked evidence of experts. If the testimony of the defendant to the effect that he removed the pieces of turbinate bone and examined them was reasonable and worthy of belief, why, questioned the court, did he push a probe through the nasal cavity and why did he tell the plaintiff that the bone must have gone down? Why did he make several x-ray and fluoroscopic examinations? The defendant's testimony, said the court, is inconsistent with what he did at the time of performing the operation and also with his subsequent acts. There is a sharp conflict in the testimony as to whether or not the fragments entered the plaintiff's lungs. The question was submitted under appropriate instructions to the jury. They saw fit to believe the plaintiff and her witnesses, and, concluded the court, we feel that there is substantial and credible evidence to sustain the verdict of the jury. The judgment of the trial court was therefore affirmed.—*Bennett v Murdy* (S D), 249 N W 805.

Medical Practice Acts Roentgen Treatment as Practice of Medicine—The plaintiff sued Dr. Frederick E. Diemer and Dr. Frank E. Butler, as co-partners, for a scar allegedly the result of the defendants' negligence in treating by roentgen rays a tuberculous gland on the plaintiff's neck. Dr. Diemer was not served with a copy of the summons and complaint and did not appear in the case. Evidence was adduced at the trial to show that the firm of Diemer and Butler was a corporation, organized under the laws of Oregon, to carry on the theory and practice of "Roentgenology, Radiation, Therapy." Furthermore, it was shown that Dr. Butler was an officer of Diemer and Butler, Inc., but that he had practically nothing to do with the treatment of the plaintiff and did not administer any of the treatments, which were administered by a technician. The liability of Dr. Butler was apparently predicated on the contention that as a partner he was liable for the plaintiff's injuries, even though he did not personally treat her. The trial court directed a verdict for Dr. Butler, holding (1) that the plaintiff had erred in bringing the suit against him as a co-partner of the firm and (2) that there was no evidence that the scar on the plaintiff's neck was due to negligent treatment.

In her appeal to the Supreme Court of Oregon, the plaintiff contended that physicians could not legally incorporate to practice medicine and that therefore the trial court erred in holding that Diemer and Butler constituted a corporation. The use of the x-ray machine or electrotherapy does not necessarily constitute the practice of medicine in Oregon, said the Supreme Court. Section 68-2118, Oregon Code, 1930, provides that the provisions of the medical practice act "shall not be construed to affect or prevent the following: (15) the practice of physiotherapy, electrotherapy or hydrotherapy carried on, by or under the direction of duly licensed practitioners of medicine and surgery." Under this provision, continued the Supreme Court, it is lawful for persons to incorporate to carry on the business of using the x-ray or electrotherapy. While operating the x-ray machine, the corporation was employed in operating a mechanical device which may be operated, said the court, by any one without a license from the

state, provided it is under proper supervision. The Supreme Court concurred in the finding of the trial court that Diemer and Butler constituted a corporation and that there was no evidence that the two physicians held themselves out as partners in the practice of medicine.

There was no evidence, continued the court, to show that the scar on the plaintiff's neck was the result of negligent treatment. The evidence showed that the breaking down of the tuberculous glands would itself cause a scar, regardless of the x-ray treatments. Whether the breaking down resulted from the administration of the x-ray treatment or whether it came from the disease itself was left wholly to speculation and conjecture. Where the testimony shows plainly that there are two or more causes for only one of which a defendant is liable, and the matter is left to mere speculation and guess the case should not be submitted to the jury. The manipulators of x-ray machines, in the use thereof, are to be measured by the standard of care, skill and diligence that would be exercised by a physician and surgeon of ordinary care, skill and diligence under the same circumstances and conditions, regardless of locality. Nevertheless it is necessary for the plaintiff to prove that the negligent use of the x-ray machine was the proximate cause of the injury of which the plaintiff complained. This was not done in the present case. The judgment of the trial court was affirmed.—*Doumitt v Diemer (Ore)* 23 P (2d) 918

Optometry Practice Acts Right of Board Member to Prefer Charges and to Sit in Revocation Proceedings—

After notice and hearing, the New Jersey board of optometrists revoked Gross's license to practice optometry. He brought certiorari to the supreme court of New Jersey questioning the legality of the revocation. The secretary of the board he contended was disqualified from sitting in the proceedings, since he had preferred the charge on which the proceedings were based. The supreme court of New Jersey, however, did not agree with Gross's contention. The secretary of the board, said the supreme court, had no personal interest in this matter. Section 11 of the optometry practice act (Comp St Supp Sec 127—99) expressly provides that charges may be preferred against a licensed optometrist to revoke his license by any person or corporation, or the board may on its own motion direct its secretary to prefer the charges. The secretary brought the complaint as a result of a conference with the members of the board and on behalf of the board. Moreover, the complaint was based on a matter of public record, Gross's conviction of a crime, as expressly contemplated in the act. The act concluded the court, does not intimate that when the secretary prefers charges he should not hear them, in fact, a certificate can be revoked only by unanimous vote of the board sustaining the charges. The order of the board revoking Gross's license was accordingly affirmed.—*Gross v New Jersey State Board of Optometrists (N J)*, 167 A 25

Medical Practice Acts Other Violations as Evidence

—When a defendant said the court of appeals of Georgia, division 1, is charged with practicing medicine without a license evidence tending to show that about the time charged in the indictment he treated persons other than the one named in the indictment is admissible. In such a prosecution it is proper for the trial court to admit in evidence an indictment, returned some four years previously, to which the defendant had pleaded guilty, charging him with practicing medicine without a license.—*Lyda v State (Ga)*, 169 S E 751

Malpractice Physical Examination of Plaintiff—Right of Defendant Physician to Demand—

The general rule in Texas, said the court of civil appeals of that state is that a person suing for damages for personal injury cannot be compelled to submit to a physical examination by physicians of either the defendants or the court's selection. But when such a person voluntarily exhibits the injured part of his body to a jury during the trial of his case he thereby waives the inherent inviolability of his person and his immunity from examination by experts. In such a case speaking generally the defendant may properly demand that the plaintiff submit to

reasonable examination by reputable physicians of the defendant's selection, and the trial court's refusal of the defendant's motion therefor constitutes error. But such error does not necessarily require reversal. It is only when the error has apparently or probably resulted in injury to the defendant that the judgment should be reversed.—*Kenney v LaGrone (Texas)* 62 S W (2d) 600

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Cardiac Hypertrophy in Young Adults—Levy and Rousset describe three cases presenting an unfamiliar picture. The main features were great cardiac enlargement, intraventricular thrombosis with emboli to the viscera and death within a year after the symptoms were well established. There were no signs of valvular disease or arteriosclerosis, and the blood pressure was at the normal level or slightly below it. Microscopic examination of the myocardium showed hypertrophy of muscle fibers in all, infarcts in varying stages of degeneration and repair in two, and in one of these a curious hydropic degeneration of the cells of the cardiac muscle with vacuolization of the sarcoplasm. The third case showed only a few hemorrhages between the muscle bundles. No inflammatory changes or signs of arteriolar disease were observed. Though clinically the patients presented many essential features in common the lesions at necropsy were not identical. It was not possible to state whether these cases represented a single condition at different phases of its development or were entirely unrelated in their pathogenesis. The etiology remained obscure.

Quinidine for Prevention of Auricular Fibrillation—During the past two years Gold and his associates have followed the clinical course in twenty-one patients having paroxysmal auricular fibrillation or flutter. In several of those who received quinidine in varying doses—in some up to 50 grains (3.25 Gm) daily—the attacks remained uninfluenced while, in a few in whom the attacks appeared to have been diminished in frequency or abolished at one time or another the influence of the drug could only occasionally be definitely established.

Most of these patients were ambulatory. Depression of auriculoventricular conduction by quinidine usually does not play an important part in the therapeutic effects of the drug in auricular flutter and fibrillation. However, in one case that the authors report, depression of auriculoventricular conduction by large doses of quinidine was solely responsible for the almost complete symptomatic relief during a period of more than a year. Another unusual aspect of the action of quinidine in this patient was the fact that the frequency of the paroxysms of fibrillation or flutter were not diminished but were nearly doubled during this period. The probable mechanism of this unusual reaction to quinidine is discussed. A fixed daily dose of quinidine produces its full effects very early, so that, if it has not produced toxic effects in the first few days, it is unlikely that toxic effects from the direct action of the drug will result from its continued administration for long periods of time. Thus in one of their patients a daily dose of 60 grains (4 Gm) of quinidine sulphate prolonged the auriculoventricular conduction time by 20 per cent and the intraventricular conduction time by 30 per cent after the first few days, but the continued use of this dose for 364 days did not increase these effects further. Since quinidine is rapidly excreted and shows slight "cumulation," the matter of importance in dosage is the size of the daily dose rather than the total quantity given over a period of time. The authors present evidence in support of the view that the use of a small "maintenance dose" of quinidine to maintain the normal rhythm established with larger doses exerts no appreciable influence on the persistence of the normal rhythm in the ambulatory patient, and that in general more intense quinidine effects are necessary to overcome the influences that precipitate an attack of flutter or fibrillation in the ambulatory patient than to abolish an attack while the patient is at rest.

Yeast Nucleic Acid and Cardiac Irregularities—Jezer and his associates administered a yeast nucleic acid derivative (adenosin) intravenously in doses varying from 25 to 45 mg in eight patients who developed paroxysmal tachycardia while under observation at the hospital. In paroxysmal auricular flutter and in paroxysmal auricular fibrillation the drug increased the grade of auriculoventricular block for from forty to sixty seconds. The abnormal rhythm was not abolished. In paroxysmal tachycardia of auricular origin the drug temporarily abolished the ectopic rhythm in one case and was ineffective in restoring sinus rhythm in a second case. In paroxysmal tachycardia of supra-ventricular origin there was no effect on the rate or rhythm of the heart. Ventricular standstill for periods of from 1 to 9.2 seconds followed the administration of the drug in the patients having an abnormal rhythm of auricular origin. During these periods the patients experienced giddiness, faintness and precordial pain. The symptoms disappeared with the return of ventricular contractions. In man the yeast nucleic acid derivative is of doubtful therapeutic value in paroxysmal tachycardia of auricular origin and of no therapeutic value in the other ectopic rhythms that were studied by the authors.

Multiple Myeloma Complicated by Intestinal Obstruction Due to Amyloid Infiltration—Randall presents a case of multiple myeloma in which the intestinal symptoms associated with increasing distention and audible and visible peristalsis and the marked presence of gas in the small intestine were characteristic of mechanical obstruction. He states that it was difficult to say what the etiologic factors were clinically, and even at operation diffuse metastasis to the small intestine was considered. From the postmortem observation it was evident that little functional activity could have taken

place. The walls of the intestine were rigid and anemic and intestinal contractions were consequently rendered ineffectual. The author believes that the explanation given by Lubarsch and Borchardt is applicable to his case. They believe that the infiltration of the musculature of the intestine with amyloid causes a paralysis of peristalsis to a large extent and acts as a mechanical obstruction. This is certainly a type of case that no known therapy, operative or otherwise, could benefit. In the author's case the amyloid was confined particularly to the circular muscle of the small intestine and none was found in the colon. In contrast to Huefer's case, there were no ulcerations in the mucosa and no amyloid in the villi or submucosa. There were large albuminous casts in the tubules of the kidneys, practically obstructing their lumens and in turn causing the epithelial cells to become swollen. Microscopic observations accounted for the clinical evidence of kidney damage. Furthermore, this picture may account for interpretation of the changes of the kidney in myeloma as a nephrosis, though in this case the condition appeared to be essentially an obstructive process. There was no amyloid found in the kidney nor was there any glomerular damage.

Amniography with Skiodan Injections.—Adair and Davis outline a method for amniography with skiodan in which the patient should be placed in the supine position. The bladder should be empty. The skin is sterilized at the site of the proposed puncture. Local infiltration anesthesia is used. The 40 per cent solution of skiodan should be warmed to body temperature and from 15 to 30 cc injected through a needle into the amniotic cavity. A 3 inch flexible 19 gage needle is used. The site on the abdomen should be selected with reference to the fetal position, and the needle inserted where there is a maximum of amniotic fluid and a minimum of fetal parts. It should be inserted only far enough to secure amniotic fluid which is drawn up into the syringe, mixed with the skiodan and re-injected. The patient should turn a few times after the needle is withdrawn to facilitate mixing the solution with the

amniotic fluid. A good diffusion is obtained within an hour and a roentgenogram may be taken at the expiration of that time, or sooner if necessary. The roentgenograms have usually consisted of a lateral and an anteroposterior view. The chief things that can be visualized by the presence of this radiopaque material are (1) the amniotic cavity and usually that portion which lies over the placenta, (2) the fetal soft parts, including at times the fetal rheneva, such as the cord, and (3) an intensified shadow of the fetal skeleton.

Chlorothymol as an Antiseptic in Obstetrics.—Beck used a 1:500 and 1:1,000 solution of chlorothymol in 20 per cent alcohol and 10 per cent glycerin in the preparation of the vulva for delivery in 164 cases. The patients did not complain of irritation from its use. The tissues did not show any evidence of irritation. Laboratory experiments indicate that the commonly used antiseptics when diluted sufficiently to become non-irritating are much less efficacious than nonirritating solutions of chlorothymol in 20 per cent alcohol and 10 per cent glycerin. The clinical results in the 164 cases in which chlorothymol was used were better than those following the use of mercurchrome and iodine in a control series of 164 cases in spite of the fact that a larger number of the various factors which might cause morbidity were noted in the chlorothymol group.

Blood Injections to Lessen Brain Hemorrhage.—Carr states that the employment of blood and blood serum intramuscularly in babies born under abnormal conditions of labor is apparently beneficial. The immediate effect is to stimulate respiration, lessen venous congestion and establish by lessening the pressure in the veins, a better balance in the systemic circulation. The babies in whom blood was injected show that this procedure is not injurious and may be used without injury. The author believes that injections of blood are indicated not only in cases of delay but also in babies with severe jaundice such as icterus neonatorum gravis.

Cytology of Glioma Group.—From his study of 120 intracranial tumors, including seventy gliomas, Cox concludes that names with an embryogenic significance do not in all cases give the true values of the cells described. This in particular applies to the medulloblast and to certain of the spongioblasts and astroblasts. The neuroblast, a cell that is difficult to identify, may be confused with included nerve cells, cells of the astroblast type, and even with certain anaplastic, rapidly subdividing cells. The nature of a tumor will frequently be interpreted more correctly by the assumption of anaplastic changes overtaking a well differentiated tissue rather than ascribing it to differentiation of embryonic cells. The medulloblastoma of childhood possesses certain qualities that suggest the possibility of an embryonic origin. The ordinary gliomas appear to fall into certain categories: (1) tumors of adult tissue (astrocytoma and its modifications, ependymoma and its modifications, oligodendroglioma, pinealoma and adult ganglioglioma), (2) highly anaplastic tumors that may occur independently or in association with any of the foregoing (glioblastoma multiforme), (3) transitional forms between the foregoing (astroblastoma, polar spongioblastoma), (4) medulloblastoma (possibly a true embryonic tumor) and (5) rare tumors of the type of medulloepithelioma and neuroepithelioma, concerning which no opinion is expressed here. The mitotic figure content of such tumors offers the most accurate index of their activity, rather than deductions derived from their resemblance to embryonic cells. The difficulty in distinguishing between truly neoplastic cells

and those that are derived from the glial tissue is discussed in some detail. The great advantage of postmortem material as opposed to operative fragments is apparent.

Fibroma of the Breast—Halpert and Dial report a case of fibroma of the breast in which the breast was the site of neoplastic growth on two previous occasions. The structure of the tumor removed at the first operation is not known. The growth removed at the second operation was a fibro-adenoma. The growth removed at the third operation was a pure fibroma in which the connective tissue closely resembled the connective tissue elements in the second growth. The question arises whether there is any causal relation between these growths or whether they are independent tumors arising at different times in the same breast. The latter seems to be the more plausible explanation, since there is no morphologic evidence that any of these growths were malignant. The tumor presented a sharply demarcated, oval, firm, elastic, lobulated mass measuring 4 by 5 by 6 cm. It cut with increased resistance and a gritty sensation, disclosing smooth, glistening, pearly white surfaces with a pattern of interlacing strands and whorls. It contained no glandular or adipose tissue. The breast tissue proper measured 6 by 8 by 10 cm. The nipple and areola appeared intact. Microscopic preparations showed the tumor to be composed of a fairly vascular, rather loose fibrous connective tissue containing no epithelial elements. It was surrounded by a thin but definite connective tissue capsule which separated the tumor from the surrounding normal tissue of the breast. The cell nuclei and the fibrils ran in interlacing streams and whorls. In some areas the connective tissue was as loose as embryonic tissue, in others it was fairly dense. The cell nuclei were spindle shaped and not hyperchromatic. Mitotic figures were scarce. No areas of necrosis were noted elsewhere in the preparations. When the patient was seen last, eight months following operation, there was no evidence of recurrence.

Iodized Poppy-Seed Oil in Bronchography—Amberson and Riggins state that in most cases retained iodized poppy-seed oil is gradually discharged through the bronchi. Direct absorption through the lung occurs to only a slight degree, if at all. A slight exudative reaction usually occurs about deposits of the iodized oil in the healthy lung but this seems not to be harmful in the clinical sense. The transudation of edematous fluid may be considerable and this may account for the rapidly developing roentgenographic lobar opacity reported by some authors. The oil may be retained for days months or years in the pulmonary alveoli. From the roentgenologic point of view, this 'contrast medium infiltrate' is a diagnostic disadvantage. The persisting densities may impair the value of serial roentgenograms as guides for treatment. Disadvantages and dangers peculiar to the cricothyroid or transtracheal method of injection include the escape of oil into and indefinite retention

in the cervical and mediastinal tissues, the more or less serious infection of these tissues by escaping bronchial discharges, and less often, pain, dysphonia, edema of the glottis, dysphagia, subcutaneous emphysema and air embolism. Iodism is due mostly to the swallowing of the oil and absorption of iodine through the intestine. Usually it can be avoided by carefully injecting the oil in small amounts, adopting measures to prevent retention in the lungs, postural drainage of the bronchi after bronchography and, finally, the administration of a brisk saline purge. In cases of infectious pulmonary disease, mainly tuberculosis and acute or chronic suppurative conditions, dissemination or aggravation can be caused by the injection. The reasons for this are given. Serious results and several fatalities are placed on record. Cases are also cited to prove the potential—even fatal—risk of intratracheal injection of iodized oil in cases in which there is impaired cardiac or respiratory function from different causes. Rational and effective ways to avoid the disadvantages and hazards are described. By the adoption of these measures the many advantages of iodized poppy-seed oil bronchography can be achieved usually without harm to the patient.

Absence of Superior Orbital Wall Associated with Pulsating Exophthalmos—LeWald believes that congenital absence of the superior orbital wall causes pulsating exophthalmos. The condition is easily distinguished roentgenologically from sarcoma of the orbit, especially in view of the fact that there is usually deformity of the floor of the orbit in addition to the other bony changes. The inferior margin of the orbit may be lower than the corresponding region on the normal side. He reports four cases of congenital absence of the superior orbital wall, in one of which the diagnosis has been confirmed and a new orbital wall constructed by a bone transplant from the skull (Dandy). Two of the cases presented associated lesions due to the presence of diffuse neurofibromatosis (Recklinghausen's disease) and the other case, in addition to the associated Recklinghausen's disease, a congenital arterio-venous fistula of the right leg, causing localized gigantism, and a congenital deformity of the cervical spine. In the routine examination of roentgenograms of the head it is advisable for the roentgenologist to study carefully the bony outline of the orbits, in addition to a study of the nasal accessory sinuses. Enucleation of the eye, or ligation of the carotid artery, should never be performed in a case of pulsating exophthalmos, unless a roentgen examination has been made and shows no evidence of congenital absence of the superior orbital wall.

Venous Circulation of Petrous Bone—Ruskin points out (1) that the venous pathways of the temporal bone play a leading part in the dissemination of infection from the tympanic cavity and the causation of intracranial complications (2) that early extension of involvement of the venous system can be

recognized clinically and should serve as a guide for early accurate intervention, (3) that the Gradenigo syndrome should be considered a symptom of venous engorgement of the group of tympanic veins emptying into the inferior petrosal sinus, and (4) that the syndrome of temporomaxillary orbital pain, trismus and edema of the lower lid, which he describes, is of similar significance with the Gradenigo syndrome but represents venous engorgement of the veins of the tympanic cavity draining anteriorly into the pterygoid plexus and middle meningeal vein. Clinically, he has shown that the early incision of the drum membrane and the induction of free bleeding from the middle ear afford relief from the symptoms and may obviate suppuration of the petrous pyramid. It must not be construed that paracentesis and free bleeding from the middle ear will relieve advanced involvement of the petrosa with suppuration and bone coalescence. One must bear in mind that the orbital and trigeminal symptoms may be induced by mechanisms affecting the pterygoid and middle meningeal venous systems other than of petrosal origin and must be carefully differentiated to avoid unwarranted surgical invasion of the petrous bone.

Otolaryngologic Conditions Wrongly Attributed to Enlarged Thymus—Janse reports six cases that could be and several that had been diagnosed as due to an enlarged thymus whereas the lesion was entirely confined to the larynx and pharynx. In every infant with laryngeal symptoms a direct laryngoscopic examination should be made. In the majority of these cases the etiologic factor will be found in the pharynx and larynx rather than the thymus, as is so often reported. The thymus shadow is found enlarged in more than 40 per cent of normal infants. The usual roentgenographic studies of the thymus are inaccurate and are apt to give false impressions. The size of the shadow of the thymus varies in the different phases of the cardiac and respiratory cycles. The author does not feel that deaths that occurred during or following anesthetics could be attributed to an enlarged thymus. Operation should be postponed and careful preoperative care should be given all patients who show evidence of infection of the upper respiratory tract, renal or cardiac disease, fever, marked anemia, malnutrition or any other condition that might increase the operative risk. The selection of a competent anesthetist cannot be too strongly advised. All allergic patients to be operated on should be tested for the anesthetic to be administered.

Modifications of the Laryngofissure Operation—The modifications of Lore of the laryngofissure operation are based on a minute study on forty cadavers, supplemented by operative experience. This operation is not recommended in advanced intrinsic cases of carcinoma. Local or general anesthesia may be used. If a preliminary tracheotomy is performed, two incisions are made in the midline. The incision for the tracheotomy is started at the lower border of the cricoid cartilage and extended to the upper border of the manubrium sterni. Should the length of the neck permit, the suprasternal space is avoided. The dissection is carried down in the midline to the pretracheal fascia and the isthmus of the thyroid, immediately below which the trachea will be opened. Before the tracheal rings are opened a few drops of from 5 to 10 per cent solution of cocaine are injected directly into the trachea. All bleeding must be controlled and all clamps removed. The trachea is opened. If the operation is to be continued under general anesthesia, a curved metal tube attached to a rubber tube is introduced into the trachea and the anesthesia continued through it. The rubber tube is fixed to the incised skin by means of a suture and light packing about the tube prevents leakage into the trachea. The thyrotomy skin incision is then made from the body of the hyoid bone to the upper border of the cricoid cartilage and down to the level of the superficial layer of the deep cervical fascia. The cartilage is cut through by means of the Clerf saw and the larynx is opened. A V-shaped incision is made in the thyrohyoid membrane. All bleeding points after removal of the mass are easily seen and ligated. Before the soft tissues and growth from the cartilage are dissected, a light gauze strip packing inserted into the trachea through the laryngofissure will prevent any secretions and blood from getting into the trachea. The dissection of the diseased tissue from the cartilage is best begun with a knife, the operator making

sure that the plane of cleavage between the perichondrium and the cartilage is reached. A Freer separator or any thin blunt dissector is used to continue the separation. This dissection must go wide of the growth, especially in the subglottic area. Then by means of curved scissors the entire mass is removed including with it or not, as the case may require, the vocal process or more of the arytenoid cartilage. The feeding tube is introduced through the nose before the larynx is closed. Before the wound is closed, all blood and secretions are aspirated from above the tracheal packing and the packing is removed. At no time has the author found it necessary to suture the incision in the thyrohyoid membrane. The two halves of the thyroid cartilage are allowed to come together. The muscles and then the fascia are brought together with interrupted sutures. The skin wound is closed by means of the so-called Stewart suture. A small gauze roll dressing is kept in place by means of stay sutures. The upper and lower parts of the tracheotomy wound are closed after a tracheotomy tube has been introduced and the usual dressings are applied. The tracheotomy tube is removed as soon as possible. While it is in place, careful and constant suction is to be used through it. All sutures are removed between the fifth and seventh days and the patient is allowed out of bed as soon as possible.

Fungicides—The experiments of Strickler in developing a formula for the local treatment of epidermophytosis indicate that potassium iodide appears to possess the property of enhancing the fungicidal power of vaporized iodine. A 3 per cent dilution of salicylic acid and a 20 per cent dilution of benzoic acid seem capable of increasing the fungicidal properties of vaporized iodine to a slight degree. Boric acid was found capable of assisting vaporized iodine slightly. The control experiment with talc alone seemed to show that this substance does not possess any fungicidal or fungistatic properties. However, it may act as an additional barrier and it may be prudent in future chemotherapeutic investigations to use this or some other inert powder so as more closely to simulate experimentally the nonpenetrating mechanism of the human horny layer. The author proposes the following local application for epidermophytosis based on the laboratory fungicidal tests carried out in the research laboratories of the Skin and Cancer Hospital of Philadelphia, and used for months in its dermatologic clinic: 13 Gm. of iodine crystals, 19 Gm. of potassium iodide, 19 Gm. of salicylic acid, 38 Gm. of boric acid and enough 50 per cent alcohol to make 591 Gm. This preparation is applied as a paint once or twice a day.

Effect of Photothermal Radiations on Cutaneous Temperatures—Bierman found that the skin of the forehead, as well as that covering the hands and feet, was able to endure the greatest amount of heat. The heating source was a 260 watt carbon filament lamp held fixed at a distance of 18 inches from the surface of the skin during the experiment. The subject determined his own tolerance. The temperatures developed on the surface of the skin and subcutaneously when different types of heating lamps were used to create heat to the limit of comfortable tolerance were determined by means of thermocouples. The needle containing the thermocouple was inserted under the skin for a distance of one-half inch, the projecting portion of the needle was covered with absorbent cotton. The accuracy of this thermocouple was found to vary within 0.1 degree F. The greatest subcutaneous temperature was caused by the 260 watt carbon filament lamp, 40.9 C (105.6 F) and the lowest by the infra-red lamp, 38.9 C (102 F). The author concludes that lamps which emanate luminous and near infra-red rays increase the temperature of the subcutaneous area more than lamps, the emanations of which are particularly in the far infra-red region.

Actinomycosis of the Kidney—Kimball and Haining report a case in which actinomycotic lesions were found in the left kidney and the right lung. If the multiple abscesses found at necropsy had been present in the roentgenograms taken

two months before death, suggestive shadows would surely have been observed. The authors conclude that the actinomycotic organisms reached the lung in less than two months. Probably the first attack on the kidney took place several months, possibly a few years, before the patient died. When actinomycosis affects the lungs primarily it tends to produce a large solitary abscess. The finding of eight or ten small discrete abscesses argues strongly for an actinomycotic pyemia, and in this case the source of the pyemia was probably the abscess of the left kidney or its extension along the spermatic cord. Actinomycosis of the kidney may break its confines by extension and distant metastasis. In this instance the only recorded clinical evidence that might have led to a careful investigation of the left kidney was left-sided, upper abdominal pain lasting more than a month. Actinomycosis confined to the kidney may remain practically symptomless even when a large portion of the kidney is involved. In the absence of suggestive history, the diagnosis of renal actinomycosis has been made by pyelographic indications of renal tumor, by the demonstration of actinomycetes in the urine and by the discovery of the fungus in postoperative sinuses. When it can be shown that actinomycosis is confined to one kidney, the prognosis is quite hopeful if nephrectomy can be performed. Supplementary measures of attested value are chiefly the administration of iodides locally and systemically, the use of radium in the wound and of x-rays over the area of the wound.

Bismuth Injections in Treatment of Warts—Lunsford and his associates treated sixty-one cases of warts with bismuth injections. In fourteen treatment was discontinued because of illness, local pain, interference with work and lack of cooperation, of the remaining forty-seven patients thirty-nine were adults and eight were children. Thirty-seven of the adults were given intramuscular injections of 1 cc of bismuth salicylate into the gluteal region at weekly intervals. Of the thirty-nine adults who cooperated, eleven were cured. Adults who were clinically cured received from one to sixteen injections of bismuth salicylate, with an average of 5.5 injections each. An average of 7.5 injections was given in those cases in which treatment failed, the greatest number being fourteen. Two adult patients were cured after one injection.

How to Reduce the Cancer Mortality—According to Bloodgood, cancer never begins in a healthy spot. This abnormal spot must be looked on as a new growth or a tumor, but the cells at first, though abnormal, are not yet malignant. The usual verified cause of this abnormal spot not yet cancer is chronic inflammation and single or repeated injury. The cure of this spot will prevent cancer. In some instances it may be cured by removing the cause. In other instances not only the cause but the spot itself must be removed. The chief protection against cancer is the same as for heart disease—periodic precautionary examinations and measures by a member of the medical or dental profession selected while one is well. Knowledge is sufficient today and there are enough trained individuals in the two professions to accomplish this prevention and to increase the possibilities of a cure of the fully developed cancer. New discoveries are not needed to place cancer among the insignificant diseases. Today, if all persons would give the medical and dental professions an opportunity from birth to old age to attempt to protect them from heart disease and cancer, there is no question that life would be a little longer and with much less suffering.

Treatment of Vulvovaginitis in Children—Peterson treated thirty-five cases of gonorrheal vulvovaginitis in chil-

dren during the year 1931. The children were treated daily according to the following general schedule: 1. A 1,000 solution of acriflavine hydrochloride was injected into the urethra until the urine was repeatedly free from pus. 2. The entire vulvar mucous membrane was painted with a 2 per cent solution of mercurochrome. 3. The vagina was filled with an ointment of 1 per cent mercurochrome in equal parts of petrolatum and hydrous wool fat. A light pad and a T bandage were applied to retain the ointment. 4. A hot sitz bath of a duration of fifteen or twenty minutes was given daily. 5. The pelvis was baked in carbon lamp appliances from half an hour to an hour daily. 6. Potassium permanganate douches (1:10,000) were given when the discharge was excessively purulent or offensive. 7. Silver nitrate was applied to the urethra and vagina twice a week after the first month of treatment. 8. The hymen was incised when necessary for efficient drainage. 9. The cervix was inspected through an endoscope and when found to be affected was treated with a 2 per cent solution of acriflavine hydrochloride, 5 per cent mercurochrome or from 2 to 5 per cent silver nitrate. 10. After the first month of routine treatment, gonococcus mixed vaccine was given in four injections: first dose, 0.15 cc., on the third day; 0.2 cc. on the sixth day, 0.25 cc., and on the tenth day; 0.3 cc. 11. Cod liver oil was given three times a day during the winter months. Smears of the urethra, vagina and rectum were taken on admission and periodically during the treatment. When three or four smears were negative for pus as well as for gram-negative cocci, the children were put under observation for two or three weeks during which time they were examined every other day until discharged from the hospital. On discharge they were instructed to report for examination every two weeks for two or three months. No arthritis developed in any of these cases. There was not a single relapse and none of the children became "pelvis conscious."

Decerebrate Rigidity After Cranial Injury—Vernon reports a case of decerebrate rigidity in a man who was admitted to the hospital one hour after an automobile accident. When picked up, his entire body was noted to be in a rigid state. He was brought to the hospital unconscious and died. Necropsy revealed a man of about 25 in rigor mortis. There were scalp wounds and a depressed fracture of the skull on the right side. The depression was 2 cm. in diameter. A subdural hematoma lay beneath the depressed fracture, but there was no gross evidence of injury to the brain tissue in this area which was 1 inch posterior to the middle meningeal artery midway between the vertex and the level of the external meatus. About 5 cm. above the point of fracture there was a ruptured meningeal vein with considerable hemorrhage about it. Subarachnoid hemorrhage extended also over the cortex of the left hemisphere. Section of the brain revealed hemorrhage in the right optic thalamus about 1 cm. in diameter. Hemorrhage in the third ventricle appeared as a clot on the choroid plexus. Section of the pons revealed widely distributed punctate hemorrhage. The lungs showed pulmonary edema. The heart and abdominal viscera were normal. It was difficult to correlate the change found in the brain at necropsy with the clinical observations. However, it was apparent that hemorrhage was extensive enough to cause in effect transection of the brain stem. The diffuse hemorrhage in the pons probably was most responsible for this condition. There was a very distinct disturbance of temperature regulation since 109.4 F. was noted about five hours after the injury. Elevated temperature undoubtedly hastened the termination of function of the already injured nerve centers. It has been stated that pontile hemorrhage leads to high temperature.

Treatment of Chorea by Induced Fever—Sutton and Dodge used intravenous injections of typhoid paratyphoid vaccine as a means of inducing fever in 150 attacks of chorea.

Comparison of the duration of chorea in the hospital in 150 attacks treated by other methods show that the duration of the attacks has been reduced from an average of 27.4 days in the mild untreated cases to 5.72, from 44 days in the untreated moderate cases to 8.56 and from 62.4 days in the severe untreated cases to 15.8 days, in the treated cases. Therefore the authors conclude that fever therapy is a satisfactory method of treating chorea. So far they have had about a 98 per cent follow up of their cases. The number of recurrences is relatively small, but since the treatment has been in use only about two and a half years and since chorea may recur after a lapse of a number of years, their present figures on recurrences have no final value.

Chronic Interstitial Nephritis with Dwarfism—Amesse and Black present a case of renal dwarfism in a girl of 4 whose mother was a morphine addict. The dwarfism is so symmetrical that the secondary or Brissaud type, in which pluriglandular insufficiency is paramount, can safely be excluded. The nonprotein nitrogen and the creatinine of the blood are moderately increased, but a disturbed relation between calcium and phosphorus is not shown. The most common symptom of renal rickets, genu valgum, is present, and the deformity has been much exaggerated during the past two months since the child's improved physical state permits more activity. While further evidence of rickets is absent, it has been recognized since the earliest observations of such conditions were recorded that the bone changes and the resulting deformities of this disease do not appear until relatively late. Mitchell gives the average age of onset in thirty-two cases as 5.16 years, and so many develop the syndrome at puberty that it is frequently known as the rickets of adolescence. Lathrop maintains that roentgenograms may be consistently negative for rickets in well defined cases, and others consider the skeletal changes quite independent of that disease.

Roentgen Visualization of Posterior Urethra—Flocks describes a method for roentgenologic study of the male urethra and bladder. The bladder is filled with a 25 per cent solution of sodium iodide, and a cystogram is taken centering over the bladder with the patient in the dorsal position. The bladder is emptied completely and irrigated thoroughly with sterile water. A 30 cc Luer syringe is filled with an iodized oil and gum tragacanth mixture. The patient is placed in the oblique position with the tube centered over the base of the bladder, the right thigh is flexed to about 45 degrees and the left thigh is extended, the patient being on the right side. The bladder is filled slowly with air, which is stopped as soon as the patient has the first sensation of fullness of the bladder, then stereoscopic air cystograms are taken. About 30 cc of the air is removed with the syringe and the urethral catheter is removed while the terminal portion of the urethra is held closed with the left hand. The Luer syringe with the contrast medium is taken up in the right hand the adapter is inserted into the urethra and the urethra is held closed about the adapter with the left hand. The assistant places the lead plate over the operator's left hand and arm. The contrast medium is injected slowly into the urethra. After about 15 cc has been injected, a varying amount of resistance is felt owing to the contraction of the sphincter. The injection is continued slowly until about 20 cc has been injected and is continued while the first roentgenogram is taken. The second film is placed into position and the remainder of the contrast medium is injected while

this film is exposed. The syringe and the adapter are removed and a catheter is inserted into the bladder. The bladder and urethra are carefully washed out with sterile water. It is possible by the use of the cysto-urethrogram to determine quite accurately the nature of the anatomic deformity in the prostatic urethra and at the neck of the bladder.

Clinical Test of Velocity of Blood Flow—Gargill employed the following method in clinically testing the velocity of the flow of the blood. All tests were performed with the subjects in the recumbent position and under strict metabolic conditions. The contents of a 10 cc ampule of a 20 per cent solution of sodium dehydrocholate were aspirated in a 10 cc sterilized Luer syringe. A vein in the antecubital space of the arm was entered and 3 cc of sodium dehydrocholate was injected as rapidly as possible. The time taken for injection as well as the time of onset of the bitter taste were registered by means of a stop watch. The time elapsed from the beginning of injection to the onset of the bitter taste was recorded as the "arm to tongue circulation time." After an interval of one or two minutes another 3 cc of sodium dehydrocholate was injected and the circulation time was again measured. The last 4 cc of sodium dehydrocholate in the syringe was used to obtain a third measurement. These three measurements usually checked within one second or a fraction of a second. In fifty normal subjects the average arm to tongue circulation time was fifteen seconds. This compares favorably with the average arm to arm circulation time found in fifty-three normal persons by Blumgart, using the radioactive method. A crude pulmonary circulation time was obtained by injecting sodium dehydrocholate into the external jugular vein. The average jugular to tongue circulation time was 118 seconds in twelve normal subjects. The circulation time was measured with sodium dehydrocholate in various pathologic states, including hyperthyroidism, secondary anemia, arterial hypertension, pulmonary emphysema and congestive failure. The results were in accord with those obtained by Blumgart with the more accurate radioactive method. In the amounts utilized sodium dehydrocholate produced no untoward reactions in more than 150 patients. The sodium dehydrocholate test recommends

itself to the clinician by its simplicity, its safety and the readiness with which it can be repeated and used at the bedside or in the office. The simplicity and safety of the sodium dehydrocholate method should enable the clinician to make use of the measurement of the velocity of the flow of the blood as an additional aid in diseases associated with dyspnea and edema.

Preventing Loss of Weight in the New-Born—Kugelmass and his associates emphasize that the initial loss of weight in the new-born is the result of dehydration and semistarvation, and it can be prevented by the administration of a solution consisting of 6 per cent gelatin (pH 6.2), 3 per cent dextrose and 0.5 per cent sodium chloride at two hour intervals throughout the twenty-four hour cycle immediately after birth. The gelatin hydrates blood and tissues, it raises the heat of the body by virtue of its specific dynamic action, and it reduces the clotting time. Dextrose brings the new-born hypoglycemia to normal. Sodium chloride raises the initial low blood chloride and favors hydration. The average loss of weight in new-born infants receiving the hydrating solution was 17 per cent, the irreducible minimum in comparison with the average loss of 7 per cent. The characteristic clinical picture of the new born is a result of the shock of birth, more effectively combated by a hydrating solution than by milk mixtures the first two or three days of life. Preventing the loss of weight in the new-born produces rapid disappearance of the so-called physiologic apathy, somnolence and stupor secondary to the shock of birth and the compensated acidosis universally present.

*Roentgenologic Diagnosis of Rupture of Liver and Spleen as Visualized by Thorotrast W F Burke and J P Madigan Washington D C—p 580

Scientific Control of Roentgenographic Results—Weyl and his associates describe tests that will aid roentgenologists in controlling variations within their laboratory which cause them difficulty in diagnosis and to collect data that may be analyzed for the purpose of standardizing radiographic technique. It is generally possible to arrange that the roentgen beam directed to about 1 square inch near a corner of each film shall be unobstructed. A two-step aluminum ladder, with steps one fourth and two-fourths inch thick, can be fixed in position in the cassette holder over the area of the film. For every roentgenogram taken there will be a record of density and of contrast in terms of these aluminum step thicknesses, which may be compared with other roentgenograms. Not only may this comparison be made between roentgenograms of a given type taken in one laboratory, but the results of several laboratories may also be compared. Analysis of the electrical problems concerned would be considerably facilitated by the collection of data from a number of laboratories throughout the country.

Roentgenologic Diagnosis of Rupture of Liver—Burke and Madigan point out that thorium dioxide sol (thorotrast) is of practical use in the diagnosis of traumatism of the liver and spleen when the physical signs are obscured by any cause whatever. It apparently exercises no deleterious effects, even when administered to patients having overwhelming infections, and may be administered intravenously immediately on indication of an intra-abdominal hemorrhage. Its use is not contra-indicated in injuries involving the liver and spleen. One half of the usual dose was sufficient to produce a shadow heavy enough for diagnosis, and a roentgenogram may be taken four hours after such an injection.

Infra-Red Photography of Subcutaneous Veins—Haxthausen emphasizes the fact that by infra-red photography it is possible to demonstrate varicose changes in the small and medium sized subcutaneous veins that can be recognized but indistinctly—or not at all—by direct observation or by ordinary photography. This type of varix is found in some cases together with varices of the large veins, while in other cases it constitutes the only form of varix present. In the latter cases, including several of ulcer and eczema of the leg, the foregoing venous changes represent presumably an important part of the condition that heretofore has been designated as "concealed" varices.

*Operation for Relief of Congenital Ptosis R. A. Greeves—p. 741

Operation for Relief of Congenital Ptosis—Greeves believes that a better result might be gained by attaching the lid to the superior rectus muscle, instead of the converse in operations for the relief of congenital ptosis. He devised the following operation, which may be performed under general or local anesthesia. A controlling suture is inserted in the conjunctiva, immediately above the cornea, and the eye is depressed as far as possible by its means. The superior rectus tendon and its attachment to the globe are then exposed by a horizontal incision through the conjunctiva and a squint hook is passed under the tendon, a silk thread is then pushed under the tendon and the hook withdrawn, the two ends of the thread being secured by Spencer Wells forceps. This thread is now used to control the eye in place of the preliminary conjunctival suture, which may be removed. Next, the upper lid is everted and the conjunctiva above the incision seized by forceps and dissected upward until the upper edge of the tarsal plate is exposed. This edge is gripped centrally by catch forceps, on each side of which a thin strip of tarsus is cut with a fine pair of bent scissors, from without inward and within outward, respectively, each strip being left attached centrally and the width of the uncut area of the tarsal plate between the strips being about the same as that of the superior rectus tendon. The strip of tarsal tissue should be as long as possible. A number 4 needle, with number 1 silk, is passed through the end of one of the strips and again through the corresponding edge of the superior rectus tendon, a similar suture is passed through the other strip and the other edge of the tendon. The sutures are drawn tight without being tied, in order to judge the relative positions of the eye and eyelid. The position of the edge of the lid should slightly overlap the upper part of the cornea. If the position of the lid is not correct, those parts of the sutures which have been passed through the tendon should be withdrawn and reinserted in the tendon in a suitable position. Great care must be taken to prevent exposure of the cornea during the healing stage. It is better not to sew the lids together. The best form of dressing is a sausage-shaped

pad placed over the upper lid and kept in place by strapping and a bandage. The sutures may be removed in about ten days.

*Diverticulum of Duodenum D. Cromie—p. 1021

Treatment of Compound Fractures of Tibia—Simpson-Smith used the following treatment with unusual success in twenty cases of compound fractures. The patient is anesthetized and the limb is iodined from mid thigh to toes. The edge of the wound is closely excised and extended up and down the leg so that an incision of not more than 5 inches is made with its center over the seat of the fracture. The incision goes straight down to, but not through, the periosteum. Careful debridement is effected and the entire area is washed with acriflavine hydrochloride. The incision is continued in the connective tissues immediately above the periosteum round the subcutaneous surface of the tibia and is extended just over the anterior and postero-internal borders, so that 1 inch of bone is "cleared" on each side of the fracture. Lane's forceps are applied to the fragments in such a way that their teeth just grip these borders. An assistant pulls on the foot to secure the necessary amount of extension and the ends of the bone are again washed with acriflavine hydrochloride before they are apposed. A special bone clamp is applied to the already cleared fragments so that it does not disturb the lateral vascular surface of the tibia. Before screwing the instrument "home" the assistant pushes the foot firmly toward the knee in order to press the two fragments hard against each other, thus ensuring that their corresponding serrations interlock accurately. The clamp is fixed, the Lane's forceps are removed and an artificially rigid tibial shaft is thus produced. A sterile gauze roll 5 inches wide is wound round the leg at the site of the fracture above and below the clamp, so that the wound is completely enclosed. The assistant, with his flexed elbows on the operating table, puts the flat of one hand under the knee and the other under the heel. The rest of the limb, from toes to mid thigh, is invested in a skin tight plaster cast. A firm plaster cast is applied in adequate thickness up and down the limb, leaving the bone clamp projecting through its substance. A window is cut through the plaster and gauze around the clamp. The plaster is allowed to dry and the bone clamp is removed. The wound is sutured and a small gap is left at the lower end for drainage, but without incorporating a tube. Dressings and a bandage around the plaster complete the operation. Antitetanic and anti-gas gangrene serum are given as a routine. The plaster cast is removed in from six to eight weeks. Another smaller one is then applied from the toes to just below the knee, and a Böhler "boot" is incorporated. The patient can walk about in this iron for a few more weeks until the union is firm.

Diverticulum of Duodenum—Cromie reports a case of diverticulum of the duodenum in which the diverticulum proper was composed of a thin layer of muscle with the submucosa and mucosa and measured 2.9 cm across the base and 2.4 cm from the base to the apex. The serous coat was not attached to the pouch, but a fold of peritoneum lay in front of it. The symptoms of the author's case did not correspond to any of the five classic groups described by Bensaude, so it is doubtful if there is any definite symptomatology. The symptoms were initiated by the filling of the sac and relief followed its emptying. The vomiting was a predominant feature. The author

cannot see how medical treatment can be of much value if the symptoms are caused by the diverticulum. Diverticula that cause no symptoms should be left alone, but others should certainly be explored. The ideal treatment is excision, but if this is impossible the diverticulum may be invaginated. Complications may call for immediate laparotomy, as in any other abdominal emergency. The author's patient has been relieved of symptoms by operation on the diverticulum for two years.

*Clinical Observations and Experiments Relating to Burning Pain in Extremities and to So Called Erythromelalgia in Particular T Lewis—p 175

Vasodilatation in the Hands and Feet in Response to Warming the Body G W Pickering and W Hess—p 213

Burning Pain in Extremities—Lewis suggests that the term erythromelalgia should be abandoned and that the name erythralgia be employed to designate a peculiar condition of painful redness of the skin, which is common to a number of diseases. The chief manifestations of patients displaying this condition in an extremity are as follows: 1 The skin of the extremity is reddened, and this reddening greatly deepens when the limb hangs down. The reddening of the skin is the result of a relatively toneless condition of the minute cutaneous vessels, and the deepening of the color on dependence is due to passive congestion and does not signify vasodilatation. 2 Burning pain is induced whenever the temperature of the skin rises to a certain level, normally insufficient to produce pain and this is so whether the heat is brought by an increased flow of the blood or is applied from outside. The same pain may be induced by extreme cold, local friction or tension. When it comes during walking it is chiefly the result of warmth and of friction. When it occurs in a limb allowed to hang down, it is due to hydrostatic vascular tension. There is no evidence that in what are called "attacks" a disturbance occurs in the central nervous system. In tissues in the "susceptible state" vasodilatation may be brought about a little more readily or more conspicuously. There is no evidence that there is any appreciable change in the flow of the blood in the normal foot on changing it from a horizontal to a hanging down position. Severe burning pain of inflamed fingers in Raynaud's disease can be caused by the quick warming of fingers occasioned by a return of the blood to them when they are cold. Normal fingers present the same phenomenon if the range of temperature change is sufficiently increased. Burning pain in the skin may follow firm stroking of the skin in some cases of urticaria factitia, and the stroked skin is subsequently unusually susceptible to warmth. Burning pain is considered to have a similar underlying basis, namely, the release from the damaged tissues of a natural substance, which acts on the pain nerve endings, lowering the threshold of these to tension and to heat, causing them to discharge pain impulses at times even under ordinary conditions of temperature.

*The Leaking Brain Abscess D McKenzie—p 797

Nasal Plastic Surgery Notes A B K Watkins—p 809

The Leaking Brain Abscess—McKenzie discusses the spontaneous rupture and gradual discharge of a brain abscess. He states that, while symptoms may be so mitigated by the leakage that the evolution of the disease is spun out, its progress continues to be downward and the end though delayed is seldom in doubt. Sooner or later the surgeon must intervene to improve drainage. The intervention will depend on the actual quantity of pus discharged and on the patient's general condition and particular symptoms. Relief to headache and pain even when complete and lasting is not sufficient to justify

a relaxation of vigilance, for a brain abscess may progress painlessly to a fatal issue. In choosing a site for drainage it is not wise to ignore the selection by nature of a certain point for drainage. Leakage, wherever it occurs, leads to the formation of a sinus with more or less firm and resistant walls. There is round the track an inflammatory zone shutting off the infected from the uninfected meningeal and brain tissues. Within the limits of this area the surgeon can make incisions and insert tubes without much risk of spreading the infection. The apparently out-of-the-way fistula may really represent the site of origin of the abscess and the stalk may actually be situated at that spot. In any case it would probably be wise to combine drainage through an outlying fistula with drainage through the apparent site of origin, whether it is the nasal sinus or the ear. Or the fistula might be selected to begin with and, if it failed to give the necessary relief, the original site could then be tried. When leakage is taking place through some inaccessible region, a direct opening should be made into the abscess. In the operation itself, safety consists in keeping as much as possible within the confines of the inflammatory zone round the discharging sinus. If the surgeon can offer sufficient drainage to the abscess without too rashly encroaching on the adjoining meninges and brain, he has done all that can be expected.

Acetylcholine in Paralytic Ileus—Abel states that acetylcholine is essential for intestinal peristalsis. Factors which produce paresis or paralysis of the intestine do so either by a diminution of the intestinal content of acetylcholine or by increasing the threshold of the nerve impulse, thus rendering the normal quantity of acetylcholine insufficient. The administration of acetylcholine is therefore the correct treatment for these conditions. In some fifty apparently normal postlaparotomies he used acetylcholine as a routine, starting with 0.1 Gm thirty-six hours after the operation and repeating this dose every six hours until passage of flatus or feces occurs without enemas. This usually happens in from six to twelve hours, but as there was severe general peritonitis in many of these cases the author's impression has been that their postoperative course has given rise to less anxiety than it would have done without the acetylcholine. He feels that many more cases must yet be treated before advising acetylcholine as a routine in the postoperative treatment of every laparotomy. He has made it a practice to give these patients 0.1 Gm of acetylcholine hourly for six doses. Many unnecessary operations have been avoided and no untoward effects produced in organic obstruction cases. Most patients with severe postoperative distention, gas pains and paresis of the intestine are considerably improved by the administration of acetylcholine by intramuscular injection. In paralytic ileus, acetylcholine appears to be almost specific in curing the condition.

Phosphoreosotic Polyneuritides—Roger and Recordier made a study of three forms of polyneuritis, etiologically different but presenting the same symptomatology polyneuritis due to constant intake of creosote phosphate compounds, as in tuberculous patients, paralysis due to consumption of adulterated Jamaica ginger and polyneuritis due to administration of the abortifacient apiol (dimethylmethylene ether and allyl tetroxybenzene). These polyneuritides are characterized almost exclusively by motor symptoms of the paralytic type. They destroy only the Achilles tendon reflexes. Their evolution is long but habitually favorable. They are due to triorthocresyl phosphate, the specific action of which is demonstrated by its cumulative property. This substance was isolated from the extracts of ginger and from apiol compounds and administered to animals, in particular to the hen. The experiments showed a clinical picture analogous to that presented by man, with severe lesions of the peripheral nerves associated with slight alterations of the anterior horns of the spinal cord. The authors corroborate their results by referring to Smith, who for several consecutive days administered to rabbits lethal doses of phenolphosphate of triphenyl, tricresol, triorthocresol and triparacresyl phosphate and concluded that under these circumstances there is no accumulation and that the rabbits survive, while the triorthocresyl phosphate is accumulated in the organism.

*Experiences and Reflections on Mechanism of Spinal Analgesia J Abadie—p 133

Mechanism of Spinal Analgesia—Abadie discusses five questions about the technic of intraspinal analgesia. The preliminary withdrawal of spinal fluid does not change the intraspinal pressure enough to alter materially the diffusion of the introduced anesthetic but produces a compensatory current toward the cranium which carries the anesthetic with it. The diffusion of various anesthetics depends in vitro on their specific gravities and on diffusible qualities apparently independent of the specific gravity. Application of in vitro observations to living intraspinal conditions cannot be made. Forceful injection, the author believes, causes the injected anesthetic to rise higher only when it is of greater density than the spinal fluid. The simplest technic possible should be used in spinal anesthesia until some of the points are better elucidated.

Influence of Trichomonas in Vaginal Secretion on Course of Puerperium—Schellenberg reviews the literature, showing that the reports about the incidence of trichomonads in the vaginal secretion differ widely. The author's tests on parturient women revealed them present in 99 per cent of his cases. He compared the course of the puerperium in women with and without trichomonads in the vaginal secretion and found that the number of complications (increased temperature and prolongation of the puerperium) was only 0.8 per cent higher in the women with trichomonads than in those without. When only the temperature curves were taken into consideration it was found that the afebrile cases were but 1.6 per cent more frequent in the women without trichomonads in their vaginal secretion, but in spite of this the women with trichomonads

could leave the clinic on the tenth day in a larger percentage of cases than could the women without trichomonads. He is convinced that they are of no importance for the course of the puerperium and he is inclined to believe that they are harmless parasites. The author emphasizes that an aseptic parturient canal, that is, one which is free from exogenous micro organisms, is the most important factor in the prevention of puerperal complications. He thinks that during the last six weeks before delivery the following rules should be observed by the pregnant woman: 1 Coitus should be abstained from. 2 No vaginal douches should be taken without the physician's orders. 3 General baths should be dispensed with in favor of sponge baths. 4 If the use of public toilets is necessary, contamination should be guarded against. 5 Manipulation of the genitalia should be avoided and, if necessary, should be preceded by careful cleansing of the hands. 6 The woman should not be obliged to take care of members of the family who have suppurating wounds. During the six weeks following delivery there should be no coitus, no douches and no tub baths, only sponge baths.

*Anatomic Changes of Gallbladder and Variations of Bacterial Flora of Bile in Cholecystogastro Enteric Anastomosis G Scollo—p 40

Electrolytes of Blood in Intestinal Occlusion—Cataliotti studied the alterations of the calcium, magnesium and phosphorus content of the blood in ten dogs in which experimental obstruction of the bowel was performed in high, middle and low sites. About twenty-four hours after operation there was a temporary lowering of the blood calcium content, and at the end of the experimentation the calcemic rate was higher than at the beginning. The increase in blood calcium was constant in all experiments and was not influenced by the seat of occlusion. The phosphorus in the blood was also diminished temporarily during the first twenty-four hours, but in its subsequent progressive rise it did not attain values superior to normal and was not influenced by the seat of occlusion. The magnesium increased immediately after operation and continued to increase indefinitely. The values of calcium and phosphorus tended to increase with the aggravation of the clinical picture. The results of the author and those obtained by Ruggeri confirm the report that intestinal occlusion, whether in high, low or medium sites, causes an increase in the calcium and phosphorus of the blood. Hepatic and renal alterations may have great importance for the variations of the blood calcium content. The liver actively participates in calcium metabolism and any alteration of the liver, even if only functional, renders it incapable of retaining its salts. Alterations in the kidney, whether anatomic or functional, show a notable diminution in the elimination of calcium salts and thus a great retention of them in the blood. When normal digestion is disturbed through defective biliary secretion, the excretion of phosphorus by the lower intestine is altered in the form of fecal tricalcic phosphate, and the phosphorus liberated from its combination with calcium, is absorbed and eliminated by the kidney. If the kidney is altered the phosphorus is retained in the blood in the form of alkaline phosphates and is therefore increased. The author states in conclusion that quantitative changes of the electrolytes calcium magnesium and phosphorus occur independently of the seat of occlusion.

Changes in Gallbladder in Cholecysto-Entero-Anastomosis—Scollo experimented on dogs with various types of anastomosis between the stomach, the gallbladder and the intestine and found that, if the animal survives, the cystic bile constantly contains pathogenic micro-organisms irrespective of the type and location of the anastomosis. The infections as well as the invasion of germs in the contents of the bladder are due more to the size of the anastomotic mouth and to the reflux from the digestive tube than to the segment of the digestive tube joined to the gallbladder. The author maintains that, the lower the location of the anastomosis in the gastro-enteric canal, the greater the danger of infection. Bacillus coli is the most commonly found micro organism in the cystic bile after anasto-

mosis Next in order are the staphylococcus and the streptococcus The bacterial flora tends to diminish progressively from the time of operation Cholecystogastro-entero anastomosis occasions notable anatomic changes in the gallbladder The gallbladder is transformed, through its new function of directly discharging the bile, into a canal similar in type to the common bile duct Histologically, it presents constant traces of inflammation, mainly localized in the mucosa and in the limitrophic zones of the neostomy These inflammations subside in time and the necrosis of the mucosa appearing toward the fiftieth day is replaced three months after operation by a regeneration hyperplastic in type coming from the zones of the adjacent healthy mucosa Biliary derivations, however, influenced by the mechanism of the histologic changes and the presence of bacterial stimuli and toxic irritants in the gallbladder, should be considered a favorable ground for the initiation of inflammatory processes due to micro organisms from other parts of the organism

Insulin-Sugar Therapy in Experimental Hypophyseal Hyperthyroidism—Loeser reports the results of the simultaneous administration of the thyrotropic substance of the anterior hypophysis and of large doses of carbohydrate and the effects of insulin and sugar on the glycogen content of the hyperthyroidized liver The experiments were made on guinea-pigs He found that the glycogen deficiency of the liver produced by the increased activity of the thyroid reaches its maximum on the eleventh day of the injections of the thyrotropic substance At this time the liver is practically free from glycogen The simultaneous administration of large doses of carbohydrate (levulose) does not compensate for the loss of glycogen by the liver Administration of insulin and sugar to hyperthyroidized animals restores the glycogen supply of the liver The author thinks that the compensation of the glycogen deficiency following treatment with insulin and sugar makes it appear possible that the change in the carbohydrate metabolism

is to be found not in the hyperthyroidized liver alone but perhaps also in the pancreas and in the suprarenal system The insular apparatus of the pancreas showed no morphologic changes indicative of such an assumption However, recent investigations indicated that a hypertrophy of the suprarenal cortex always accompanies the experimental hyperthyroidism

Coagulation Time and Ovarian Function—Küstner and Schulz demonstrate that irradiation with red light rays produces changes in the otherwise rather constant blood coagulation time Since the changes do not develop in the absence of the ovaries they cannot be the result of a direct action on the blood but must be accomplished by way of the ovaries On the other hand, the change in the coagulation time following irradiation with red light rays presents a biologic test for the function of the ovaries, for only adequately functioning ovaries lead to a prolongation of the coagulation time Thus, a prolonged coagulation following irradiation with red light rays indicates normal function and reactivity of the ovaries, whereas an unchanged coagulation time indicates deficient or entirely lacking ovarian function The authors point out that this is a further proof for the great significance of the red rays for the biology of the secretory glands

Changes in ST Interval Following Exertion—Von Mentzingen describes the changes in the ST interval of patients and of normal persons following the exertion of bending the knees ten times She found that a leveling of this deflection indicates a functional and occasionally a reversible cardiac impairment and that the negativity of this wave generally indicates a severe lesion produced by a true myocarditis A heightening of the T wave is extremely rare following the work test and does not permit a definite interpretation

Economic Treatment of Pernicious Anemia—Franke compares the results obtained with fresh liver, liver preparations and stomach preparations in the treatment of 118 patients having pernicious anemia with the efficacy of arsenic and of blood transfusions in sixty-three patients He reaches the conclusion that the most effective treatment, particularly in the most severe forms is the combined use of liver juice and stomach juice It requires only half the time needed by treatment with liver juice only, with liver and blood transfusion or with injection of liver extracts The most suitable measure to retain the normalized condition (more than four million erythrocytes) is one weekly injection of from 5 to 10 cc of liver extract and daily oral medication with 3 Gm of reduced iron The author recommends the medication with iron during the continuous treatment because of the favorable effect on the general condition and on the nervous disorders, and because many patients cannot be kept above the four million mark without the administration of iron Stomach preparations alone did not meet the requirements more effectively than orally administered liver preparations The author compares the cost of the various methods of treatment He shows that liver treatment alone requires much more time and consequently is almost twice as expensive as the combined liver and stomach treatment For the continuous treatment liver and iron is much less expensive than is the use of fresh liver alone

Nycturia as Symptom of Central Nervous Disturbances—Jores designates as nycturia the condition in which the quantity of night urine is greater than that which is eliminated during the day. In a former report he had proved that, particularly in patients with cardiac and renal disorders, nycturia, the inverse type of water elimination, is extraordinarily frequent. However, observations on a large number of patients revealed that nycturia may also exist in the absence of cardiac and renal disturbances. He relates the clinical histories of three patients, which indicate that nycturia concurs with sleep disturbances, particularly of the narcoleptic or epileptic type. He mentions two patients with emaciation, lack of specific dynamic action, polyuria and high sodium chloride content of the urine, in whom disturbances in the sympathetic regulation of the hypophyseal-mesencephalic system were diagnosed. These cases indicate that the cause of the inverse type of urine elimination is to be found in the mesencephalon. The author shows that the majority of patients with gastric ulcer have nycturia, and in this connection he points out that, in patients with ulcer, disturbances of the sympathetic regulation particularly in the form of vagotony, play an important part. He cites another case, in which vagotonic symptoms concurred with nycturia, and in summarizing the different observations he emphasizes once more that the inverse type of water elimination, nycturia, is caused by a disturbance in the hypophyseal-mesencephalic system.

Active Immunity in Syphilis—Kollé and Prigge point out that the problem of immunity against syphilis is not solved. They show that symptomless infection, that is, general infection without the formation of primary lesions, plays an important part in this problem. The transmission of glandular material by inoculation is the only way to demonstrate the symptomless infection. The authors made systematic tests on syphilitic rabbits subjected to an intense arsphenamine treatment during either the early or the late period to determine whether the lack of development of a primary lesion is the sign of a local cutaneous immunity (chancere immunity) or of a true general immunity. One group of infected animals were subjected to arsphenamine therapy from three to eight months following infection. After completion of the arsphenamine treatment they were left alone for six months and then were exposed to reinfection. From six to eight months after this, their lymph nodes and testes were extirpated and inoculated into new animals. The controls were syphilitic animals that received arsphenamine therapy just like the animals of the first group, after the corresponding period they were not treated with syphilitic material but with normal material. These experiments proved that there is a chancere immunity but no true general immunity. The method of experimentation chosen by the authors also indicates how Chesney arrived at his erroneous conclusion that a true active immunity develops in syphilis. Chesney performed the reinfection too soon after the arsphenamine therapy, for the elimination of arsphenamine is drawn out over considerable periods and the arsphenamine still present shortly after the treatment prevents the multiplication of newly introduced spirochetes. The second cause of Chesney's erroneous results is that he transplanted the glandular material too soon after the reinfection. The authors point out that the absence of true immunity to syphilis refutes the objection that chemotherapy during the incipient period prevents the development of an immunity. There never exists such an immunity during an early or the late period.

Local Myxedema in Exophthalmic Goiter—Arzt reports the history of a woman who developed broad-based, firm tumors with a papillary surface on the extensor aspects of the legs.

The histologic picture indicated that the tumors were a local myxedema. The protrusion of the eyes and the statement that she underwent an operation for exophthalmic goiter led the author to classify the case with the cases described by Wilhelm Richter as local myxedema in exophthalmic goiter.

Urea in Blood and in Cerebrospinal Fluid—Leopold shows that under physiologic conditions the urea content of the blood and that of the cerebrospinal fluid vary in individual cases. In the blood, the values fluctuate between 17 and 56 mg per hundred cubic centimeters and in the cerebrospinal fluid between 13 and 48 mg. The urea content of the cerebrospinal fluid is largely dependent on the urea content of the blood. However, the blood is not the only source of the urea found in the cerebrospinal fluid. Under certain conditions it is probable that at least a portion of the urea demonstrable in the cerebrospinal fluid is produced in the cerebrospinal fluid itself or in the central nervous system. Under physiologic conditions the cerebrospinal fluid generally contains less urea than the blood, as a rule about 85 per cent. The percentage increases in case of disturbances in the cerebrospinal fluid and decreases again as the condition improves. This observation, however, is of only theoretical significance. It does not permit conclusions about the existence of pathologic processes in the central nervous system, nor can it be utilized for the prognosis.

Stained Flocculation Reactions—Hecht points out that since the flocculation reactions are based on colloid chemical processes, the introduction of dye colloids could be tried in order to make the flocculation not only more clear but also more voluminous. The aim of his research was to devise a flocculation reaction in which the precipitating extract carries a portion of the dye along, so that, in case of a positive reaction, the fluid that remains after flocculation would be colored differently from that in a negative reaction (in not precipitated extract). The experiments were made primarily on the conglobation reaction of Hecht and Müller. However, the results indicate that they can be made on all flocculation tests of syphilis which employ alcoholic extracts without the addition of balsam (Sachs-Georgi reaction, Kahn reaction and so on). The method consists (1) in a selective staining of the extract with a dye that, following precipitation of the colloid extract, leaves the remaining fluid uncolored, and (2) in a contrast staining of the sodium chloride solution (fluid free from extract) with dyes that stain the colloid extract only slightly or not at all. Of the numerous lipid stains, sudan III was the only one that proved suitable. The concentration of the stain is determined by means of titration. Sudan is introduced in a powder bottle containing the extract. After shaking, the mixture is left to stand, and thus a saturated extract dye solution is obtained. Then the Hecht-Müller conglobation reaction is done according to the usual technic by setting up the undiluted stained extract and also dilutions of the stained extract with the unstained extract in various ratios.

Stained extract	5 cc	4 cc	3 cc	2 cc
Unstained extract	1 cc	1 cc	1 cc	1 cc

With this model it is easy to find the dilution in which the extract, in case of a positive reaction contains sufficient dye taken up by the precipitate so that the fluid is completely or almost completely clear, whereas in the nonflocculated extract (negative reaction) a reddish fluid is observable. As contrast stains, numerous dyes nonsoluble for fats can be used. Among others the author mentions Löffler's methylene blue. Here likewise titration is advisable. The stained sodium chloride solution should contain only so much contrast dye that during mixture with the dyed extract it does not reveal its own stain.

If in case of positive reaction the red stained extract is concentrated in the conglobate, the contrast stain must be clearly visible, whereas, in case of negative reaction, there usually is a turbid fluid. The reaction should be read against a white background.

Treatment of Esophageal Stenoses and of Cardiospasm—Lotheissen recommends progressive dilation for the treatment of cicatricial strictures of the esophagus, which frequently develop following corrosion with acids or other caustics. He states that in cases in which dilation fails esophagoplasty can be done, but he found that this is rarely necessary. He discusses strictures caused by tumors. Benign neoplasms, such as wartlike papillomas and myomas, rarely cause disturbances; only fibromas and lipomas occasionally become large enough to obstruct the esophagus. They can generally be detected by roentgenoscopy or esophagoscopy. In the course of esophagoscopy, pedicled polyps can usually be removed by means of the galvanocautery. In cancer of the esophagus, surgical removal is still the most reliable therapeutic method. The removal is comparatively easy only if the growth is in the cervical portion. Here the defect can be repaired by esophagoplasty. Because of a tendency to metastases the results are not often permanent. The majority of esophageal cancers develop within the thoracic cavity, and the results of resection are poor. By gradual dilation it is frequently possible to improve deglutition at least temporarily. If the patient refuses a gastric fistula, the use of the catheter may become necessary, but the latter procedure may cause undesirable hemorrhages and even may accelerate the growth of the cancer. Irradiation has not been very successful in the treatment of esophageal cancers. For the alleviation of pain the author recommends medication with silver nitrate. If thick mucus accumulates above the stricture and troubles the patient a tablespoonful of a 1:100 solution of sodium bicarbonate will make it more fluid, so that it will pass the stenosis. In case of painful deglutition an anesthetizing solution can be swallowed five minutes before eating. Spastic conditions of the esophagus, particularly cardiospasm, are much more amenable to treatment than are the organic stenoses. Cardiospasm becomes manifest during food intake and is the result of a disturbance in the innervation. Antispasmodics are helpful, but more important is the local treatment. Dilation instruments employing balloons are sometimes employed. The author evaluates several surgical methods, but he thinks that nonsurgical dilation should always be tried first.

Method for Detecting Tendency to Scoliosis—Bragard mentions symptoms such as fatigue after physical exercise, myogelosis in the erector spinae muscles, anemia and a tendency to sweating as frequently indicative of progressive scoliosis and describes a method that permits early detection of a tendency to scoliosis by testing the compression pain of the thorax. The patient lies on his back with the hands under his head and takes a deep breath. During expiration the examiner presses both hands forcefully to both sides of the thorax. In older children the hands are first applied to the side of the upper and middle ribs which means obliquely to the course of the ribs, and then the procedure is repeated over the middle and lower ribs which are pressed almost transversely. Then the patient is turned to the side, and each half of the thorax is compressed. Again

the hands are pressed obliquely, almost transversely to the course of the ribs. The hand that presses the back is at a slightly higher level, so that pressure and counterpressure strike the same ribs. The procedure must be repeated over the lower ribs if necessary. A healthy person experiences no discomfort from the compression of the thorax, provided he breathes properly. Persons who are threatened by progressive scoliosis complain of pain, which in high bilateral compression appears particularly in the costal cartilages along the sternum. If pressure is exerted lower down, the pain is most intense in the anterior axillary line. Pain on compression of the ribs between the fifth and the tenth is most significant. In unilateral compression the patients frequently state that one side hurts more than the other; the convex side more in the case of slight curvature and the concave side more in severe deformity of the thorax. The author thinks that the phenomenon is due to the bending of the ribs that have become elastic.

Tonsillectomy in Endocarditis—Curtius and his associates performed tonsillectomy on forty-one patients with endocarditis. In twenty-nine they removed the tonsils during the nonfebrile interval and in twelve during the acute attack. They found that tonsillectomy is readily accomplished during the acute attack although hemorrhages and postoperative increases of temperature are more frequent than is the case in operations during the interval. Bacteriologic examination of the tonsils revealed hemolytic streptococci, particularly in the septic forms of the disease. In a case of endocarditis lenta in which *Streptococcus viridans* was demonstrated in the blood, this organism was not demonstrable in the tonsils. In two patients with endocarditis lenta, neither the blood nor the tonsils contained pathogenic microorganisms. The tonsillar microorganisms of two patients were examined for cardiotropic behavior, but such behavior could not be proved. Of twenty-three surviving patients who were reexamined later, only three complained of occasional difficulties in swallowing and of throat irritation. These symptoms were probably caused by nasal abnormalities that existed previous to the tonsillectomy. In cases of this type, disorders of the nose should be corrected. In eight cases of endocarditis lenta the tonsillectomy neither retarded nor checked the fatal course. Thirteen of twenty-three patients with endocarditis showed a disappearance of the cardiac symptoms together with the pharyngeal symptoms. Septic and rheumatic manifestations were favorably influenced in fourteen patients. In febrile florid endocarditis, tonsillectomy brought no advantages and the authors think that it should be done during the interval, when the patient is free from fever. They observed that existing cardiac lesions often improved after tonsillectomy. However they found that, if signs of decompensation existed before tonsillectomy was done, a continuous exacerbation may be expected. Involvement of the kidneys is no contraindication to tonsillectomy, but the renal symptoms as a rule were only slightly influenced by it. The subjective condition of the patients with endocarditis improved generally to the extent that the cardiac and pharyngeal symptoms improved. A discrepancy between the subjective and objective aspects could be traced in two patients to psychic factors.

Scarlet Fever Blanching Phenomenon—Wieck shows that the blanching phenomenon is a great help in the diagnosis of scarlet fever, and he thinks that this test should be made in every case. However, to perform it with the scarlet fever antistreptococcus serum involves dangers due to the allergizing factor of the horse serum. There is the possibility of perform-

ing it with convalescent serum, but, since the patients are usually children, the withdrawal of sufficient amounts of serum meets with difficulties. The third possibility is the use of normal serum. The fact that with increasing age there is a considerable increase in negative Dick reactions was an inducement to study the serums of older persons for their blanching capacity. The author obtained serums of thirty-seven persons, aged 40 or more, and he found that, even though they had not had scarlet fever their serum had an intense blanching capacity. The results obtained with these serums were superior to those produced with convalescent serum or with scarlet fever anti-streptococcus serum. A particular advantage of the normal serum is that it is obtainable in practically unrestricted quantities.

Involvement of Fetal Tissues in Uterus in Experimental Hypersensibility to Protein. E. Junghans and H. Girsensohn—p 177
*Curative Action of Iodized Oil Filling of Uterus and Tubes in Sterile Women. G. K. F. Schultze—p 180

Curative Action of Iodized Oil in Tubes in Sterile Women.—The introduction of iodized oil into the uterus and the tubes of sterile women is resorted to primarily for diagnostic purposes, but Schultze shows that in a considerable number of cases it has also a therapeutic effect. He admits that in sterility the estimation of therapeutic results is difficult and that a critical attitude is necessary if self-deception is to be avoided. However, he is convinced that in twenty-one cases or in 13 per cent of those in which roentgenoscopy revealed that one or both tubes were passable, a causal connection must be assumed between the filling with iodized oil and the subsequent pregnancy. He discusses the factors that play a part in the therapeutic action of the iodized oil filling. It is probable that the introduction of the contrast medium presents a sort of fluid probing of the cervical canal. Moreover, the dilation of the uterine cavity, effected by the contrast filling, may play a part. But the author thinks that the therapeutic action of the contrast medium is due primarily to the action on the tubes. Certain observations seem to indicate that the iodized oil influences the function of the tubes by stimulating the peristaltic action.

Pregnancy in Tubal Stump. Two Cases. O. von Schroeder—p 231

Malignant Granulosa Cell Tumor and Premature Sexual Development.—Klasten states that 48.7 per cent of granulosa cell tumors occur in women of the child-bearing period, 42.5 per cent in women of the menopausal age and 8.7 per cent in children of the prepubertal age. In a case observed by him of a girl, aged 9, he points out that, if the relations between sexual prematurity and the granulosa cell tumors are studied, two possibilities should be considered. There is the possibility of a constitutional sexual prematurity, which occasionally is hereditary and is caused by a genotypically precipitated growth impulse. In such cases of constitutional prematurity a granulosa cell tumor, as the result of a tissue anomaly in the form of a malformation of the granulosa epithelium, may become manifest as a coordinated symptom. The second possibility is the premature development of the sexual apparatus as the result of the secretory action of the granulosa cell tumor in persons with otherwise normal growth impulses. Aside from the hereditary occurrence of the first form the two types differ in that in the first the signs of sexual prematurity persist and develop further after extirpation of the tumor, while in the patients in whom the sexual prematurity is the result of the secretory action of the tumor it either disappears or at least does not develop further, provided there is no relapse. In the author's case the secondary sex characters were fully developed, but there was no indication of a hereditary predisposition to sexual prematurity.

Surgical Treatment of Prolapse.—The method described by Kovacs is based on the principle of median colporrhaphy. In the first stage of the operation, he resects from the posterior and anterior vaginal walls, in transverse direction and 1 cm away from the external uterine opening, mucous membrane flaps, which measure 2 cm on the narrow side and 3 cm on the wide side and approach the rim to within 1 cm. Each flap terminates laterally upward in a sagittal J or L shaped strip of from 1.5 to 2 cm in width, which in turn slants off into a point that is directed outward and ends in the external and median third of the vaginal wall. The two flaps are exact reflections of each other. The wound surfaces that have been formed in this fashion are joined in their entire length with knotted catgut threads, and the prolapse is eliminated. There remain on the one side of the septum, a vagina of normal width but shorter by 3.5 cm and, on the other side, a vaginal canal the width of a pencil, and also small cystoceles and rectoceles. The second phase of the operation consists in a thorough anterior but particularly posterior plastic repair. By means of reconstruction of the perineum and by curving the vaginal axis so that the concavity is directed forward, not only the cystoceles and rectoceles are eliminated but the vaginal orifice is narrowed. Moreover, at its external end the vagina is lengthened to the same extent it had been shortened by the septum in front of the mouth of the uterus. The anterior concavity of the vaginal tube, produced by the repair of the perineum, places the intra-abdominal pressure on the newly formed, muscular perineum instead of on the vulvar slit and thus the action of the vaginal septum is reinforced. The operation produces on one side of the septum a vaginal tube of normal width and length, and on the other side there remains a narrow canal. The discharge of uterine and vaginal secretions is possible through both. Between the vaginal part of the uterus and the transverse septum there remains a transverse canal, which opens into both tubes. The author performed this operation on fourteen patients and generally obtained excellent results. The operation may be performed on women of all ages but it is particularly advantageous for younger women, for the cohabitation capacity is retained and even conception is still possible. Pregnancy can be carried to term, but delivery must of course be done by cesarean section.

Methods of Operating on Cysts of Upper Jaw. Clinical Evaluation. V. A. Aronson—p 91

Functional Treatment of Compression Fractures of Vertebrae.—Gorinevskaya and Dreving state that compression fractures of vertebrae constitute a characteristic trauma of workers engaged in building trades and as such demand special preventive measures. Complete restitution to full working capacity takes place in the majority of cases if correct treatment is applied. Cases complicated by total crushing of the spinal cord are utterly hopeless but constitute not more than one sixth of all cases. The author considers prolonged immobilization in plaster of Paris or leather jackets faulty, because it leads to atrophy of the bones, muscles and joints and thus prolongs the disability. A compression fracture of a vertebra is essentially an impacted fracture and Behler's suggestion that it be reduced does not accomplish its aim. The correct method from a physiologic point of view consists of systematic and methodical movements with due regard for the character of the fracture, the age, the occupation and the general condition of the patient. All exercises are carried out in the beginning in a horizontal position on an inclined plane. The movements consist of general physical exercises, which aim at strengthening of the muscles and improving the respiration and circulation. Special corrective exercises to strengthen the muscles of the spine, particularly

the extensors, are gradually added. The exercises are carried out according to a definite plan, with a definite dosage and a gradual increase in force and duration, training the patient to hold his vertebral column in a vertical position, to walk and to work. This method of functional treatment shortens considerably the period of disability. Massage and physical therapy are valuable aids in the functional treatment.

Blood Platelets in Purulent Infection—Girdin-Finkinshteyn found that infection is accompanied by oscillation in the number of blood platelets. This oscillation from the onset of the infection and following surgical intervention up to recovery is characterized by a certain regularity. It is influenced by the character, the course, the clinical picture and the outcome of the disease process. The blood platelet curve in acute purulent infection with a favorable course terminating in recovery is typical and is made up, after the operation, of two components, a rise followed later by diminution in the count down to normal. In a rapidly approaching lethal termination the platelet count falls abruptly and remains at a low level. In grave infections with alternating improvements and exacerbations terminating in death, the number of platelets falls with exacerbations and rises with improvement. The fall in the count always coinciding with the appearance of grave clinical manifestations. The more acute the course of infection the steeper the curve. Purulent infection was found to be accompanied by thrombocytosis in 80 per cent. The author found giant and tail-shaped forms in the majority of his patients. The two bore a proportional relation to the total number. These forms were found rising with the improvement in the disease process, falling with exacerbation and disappearing shortly before death. The number of giant and tail-shaped cells diminishes gradually as the patient recovers from the infection. The author concludes that the blood platelet count offers one more method of estimating the reaction of an organism to a purulent infection. A typical blood platelet curve with a typical change in the number of giant and tail-shaped cells points to a favorable outcome. Diminution in the count and disappearance of tail-shaped cells points to the gravity of the disease process. A sudden fall in blood platelets followed by persistent thrombopenia and disappearance of tail-shaped cells is indicative of the severity of the infection.

- Bronchial Asthma with Especial Regard to Allergic Form. Zaida Eriksson—p. 29.
- *Plastic Surgery for Pendulous Breasts. G. A. Björkenheim—p. 57.

Roentgen Symptom in Diverticulitis of Colon—In Jansson's case a pseudotumor had developed on the basis of a peridiverticulitis and perisigmoiditis. Careful roentgen examination is, he says, the only means of certain diagnosis in diverticulosis of the colon, and irrigoradioscopy, well carried out, is undoubtedly the best method, it is important that the contrast substance, which should be a thick fluid, be allowed to lie in the colon for one or two hours, so that the pouches may fill gradually. If diverticulitis accompanies the diverticulosis, the inflammatory process often extends to the mucous membrane of the colon causing changes in the mucous membrane relief and rigidity in the intestine. Diverticulitis seldom leads to cancer formation. When in case of tumor in the sigmoid flexure typical pouches are seen in the roentgenogram, with characteristic changes in the mucous membrane relief, and nutrition and appetite are good, the indications point to an inflammatory tumor due to diverticular sigmoiditis and perisigmoiditis.

Irritant Effect of Iodized Oils in Subarachnoid Space—Following myelography in Ruin's case of chronic adhesive arachnoiditis in which a 40 per cent iodized oil (iodipin) was used, paralysis affecting the rectum, bladder and left lower extremity occurred, the patient could not be discharged as tolerably recovered until four months after the myelography.

Plastic Surgery for Pendulous Breasts—After treating of the various operative methods for pendulous breasts Björken-

heim describes his case treated according to Joseph's second method. Sixteen days elapsed between the two sittings, and on resection 1,400 Gm. of tissue was removed from the breasts. The intervention was well borne and recovery uneventful.

- *Investigations on Intestinal Peristalsis Observed Through Window in Abdominal Wall. F. Schnohr—p. 29.
- Outfit of Urologic Instruments. O. Keller—p. 47.

Study of Intestinal Peristalsis—Schnohr inserted an oval cellophane window in the abdominal wall of twelve rabbits, when killed from two to three weeks later, the animals were perfectly well. In anoxemia or increased carbon dioxide concentration in the blood, violent contraction of the arteries in the intestine was seen, accompanied by immediate stopping of all intestinal movement. Solution of pituitary preparations repeatedly produced a peristalsis more violent than the normal intestinal contraction of an uncoordinated unphysiologic kind and of very short duration. Intravenous or intracardial hypertonic salt solutions (from 7 to 25 per cent) were usually able to produce in the paralyzed intestine long continued peristalsis of the same nature as the normal intestinal movements. The importance of this effect in the treatment of paralytic ileus is emphasized.

- Kienbock's Disease Treated with Extirpation of Os Lunatum. Fourteen Cases. A. Ringsted—p. 57.
- Pulsation in Right Carotid Artery in Arterial Hypertension. J. E. Holst—p. 79.

Kienbock's Disease Treated with Extirpation of Os Lunatum—In Ringsted's thirteen cases of Kienbock's disease, one bilateral examination from nine months to six years after operation shows that eight are well, three improved and three unchanged. The technic used consisted in dorsal removal of the semilunar bone, scraping off the cartilage of the bones articulating with the semilunar and transplantation of a sterile bone graft from the femur to the cavity.

Pulsation in Right Carotid Artery in Arterial Hypertension—Holst says that in a number of cases of arterial hypertension an abnormal pulsation arising from the common carotid artery is seen, either only on the right side of the neck or far more marked on the right side than on the left. He cites the seven cases found in the literature (Brown and Roundtree five and Beardwood, two) and reports two personal cases, of the nine cases, eight were in women. A shifting upward of the arch of the aorta and thus of the arterial branches originating from the arch leads to a reduction of the space between the two ends of the carotid, with consequent folding of the carotid and in certain cases, formation of an angular kind, the unilateral nature of the phenomenon depends on special conditions affecting the carotid on the right side.

- *Significance of Athletic Exercises for Menstruation and Delivery. Review. K. Secher—p. 59.
- Determination of Quinine Resistant Lipases in Serum. Remarks on Technic and Sources of Error in Same. V. Genner—p. 63.
- Remarks on Artificial Respiration According to Holger Nielsen's Method. J. Lindbård—p. 67.

Athletic Exercises for Menstruation and Delivery—Secher summarizes as follows: 1. Apart from quite exceptional cases, athletic exercises usually are without harmful effect on the menstrual process. 2. Sometimes they have a marked favorable influence on certain forms of pain accompanying the process. 3. Physical exercises, except swimming during menstruation seem to be safe, although competitive exercises should be avoided at this time, but there are pronounced individual differences and especially during the first two days athletic exercises should be avoided if there is attendant discomfort. 4. There is no evidence pointing to any really unfavorable effect of athletics on delivery. 5. Athletics, especially in the more strenuous form such as training for competitive sports should be practiced only by perfectly healthy women, and disorders in the pelvic region particularly should be excluded. Physical exercises during the menopause are advised, as the increased activity of the organism apparently lessens the climacteric difficulties considerably.

THE RESTORATION OF THE GENERAL PRACTITIONER

DEAN LEWIS, M.D.
BALTIMORE

In these rapidly changing times, any one who speaks of restoring anything that pertained to the old order may seem to be exceedingly rash. But recently more favorable things have been said of the general practitioner than for some time. During the economic depression he has fared better than the specialist, for more people have discovered that they could be treated in their homes, his overhead has not been high. Many consultants have changed their point of view and have condescended to make house calls. So, as far as medicine is concerned, the economic depression has automatically restored some of the old order. I have never liked the term general practitioner, for the term seems to convey the meaning of a wide, thin spread.

Osler in 1897 read a paper before the New York Academy of Medicine entitled "Internal Medicine as a Vocation" in which he said:

I wish there were another term to designate the wide field of medical practice which remains after the separation of surgery, midwifery and gynecology. Not itself a specialty though it embraces half a dozen, its cultivators cannot be called specialists but bear without reproach the good old name physician in contradistinction to general practitioners, surgeons, obstetricians and gynecologists. I have heard the fear expressed that in this country the sphere of the physician proper is becoming more and more restricted, and perhaps this is true, but I maintain (and I hope I can convince you) that the opportunities are still great and the laborers are scarcely sufficient to meet the demand.

At the outset I would like to emphasize the fact that the student of internal medicine cannot be a specialist. The manifestations of almost any one of the important diseases in the course of a few years will box the compass of the specialties. Typhoid fever for example, will not only go the rounds of those embraced in medicine proper but will carry its students far afield in morbid psychology and sometimes teach him, perhaps at the cost of the patient, a little surgery.

Osler had in mind when he prepared this address the medical consultant, for he continues "Each generation has to grow its own consultants." Samuel Mitchell, Swett, Alonzo Clark, Austin Flint, Fordyce Barker and Alfred Loomis served their day and passed on. Their work remains but enough of a great physician's experience dies with him to justify the saying

"There is no wisdom in the grave." The following quotation has much that indicates the factors that make a successful physician:

Much that made such a man what the community, to their highest profit, found him to be, dies with him. His inborn gifts and much of what was most valuable in his experience were necessarily incommunicable to others, thus depending much on his forgetting the process by which in particular cases he made up his mind, and its minute successive steps, but mainly, because no man can explain directly to another man how he does any one practical thing, the doing of which he, himself, has accomplished, not at once by imitation or by teaching, but by repeated personal trials and by missing much before ultimately hitting.

Of the successful consulting physicians of today, it will be found that many started in general practice or had their early training in the laboratory or clinic. Many of the most prominent have risen from the ranks of the general practitioner. Many consultants will rise in wrath when some one makes a remark reflecting on the general practitioner.

The medical consultant is the type that Osler had in mind—the physician. As I said in the beginning, I do not like the term general practitioner, and, in the address cited, Osler has applied the word physician to the medical consultant. The dictionary defines a doctor as one who practices medicine or surgery. The doctor that I wish to discuss practices medicine and surgery.

It is important in outlining plans to determine why graduates in medicine specialize. A little over 36 per cent of all graduates in medicine specialize. A large percentage of the graduates of some medical schools specialize. In the final report of the Committee on Medical Education and Hospitals it is stated that 75.1 per cent of the graduates of Johns Hopkins Medical School finally specialize. I have hesitated to give this figure, for the question that might arise is, With what authority does he read a paper dealing with the restoration of the doctor? On the other hand, having had some experience in this school, I might be able to say something as to why so many specialize. Johns Hopkins is followed by Harvard, 64.1 per cent of whose graduates specialize, by the University of Virginia, 61.5 per cent of whose graduates enter specialties, and by Stanford University School of Medicine with 55.8 per cent. A much lower percentage of the graduates of state universities enter the specialties, and I am rather surprised to find out that but 25.3 per cent of the graduates of the University and Bellevue Hospital Medical College and 26 per cent of the Jefferson Medical College take up special work. Several different methods have been suggested by which the ideal doctor can be developed.

Elling, in a paper read before the American Surgical Association in 1929, said that the problem of rural

Read before the Annual Congress on Medical Education, Licensure and Hospitals, Chicago, Feb. 12, 1934.

A discussion of this paper will be found in the transactions of the annual congress which appear in this issue of THE JOURNAL under the caption "News."

medicine has long been recognized as an important one, toward the solution of which the small medical college should especially devote its attention. To this end there has been evolved by the Albany Medical College a so-called five point program as follows:

1 By giving preference in the selection of medical students to those whose affiliations are in the district

2 By primarily training students for general practice and properly fitting them at moderate cost for such work

3 By providing its graduates and other hospital interns with data concerning opportunities and locations where doctors are needed

4 By cooperating with graduates and other physicians in the large district served by the school, giving them an opportunity to take graduate work and review advanced courses either formally or informally, as well as special work in all departments of the medical school

5 By suitable publicity informing rural communities of the advantage of employing their local doctor, who can care adequately for more than 90 per cent of their ills, and whose cooperation and interest is of the greatest importance in the care of the remaining 10 per cent

One of the most important features of this program is the maintenance of a liaison department between the hospital medical school, other hospitals and the profession, public health workers and those responsible for the sick poor of the surrounding territory. Such a department functions all the while and in an impartial and humanitarian manner, thus avoiding the temptation and criticism of commercialism. In this way it is possible to establish and maintain a relationship between the man in rural practice and an institution rather than with an individual, and an institution that functions at all times for the benefit of both patient and doctor.

In this institution a planned effort has been made to provide rural districts with doctors, and to provide instruction which will keep these doctors acquainted with the latest developments in medicine and surgery. In spite of these efforts, 41.8 per cent of the graduates of this medical school are engaged in the practice of the specialties.

In some institutions the development of a resident staff has led to specialization and I believe that the graduates of those hospital medical schools which have a resident staff will specialize, for from the day that they enter on the intern service most of them are looking forward to a position on the resident staff. After spending six or seven years in the hospital in one service they become specialists, and those in such a service early in their career have determined to specialize. Such an organization is intended to give opportunities to those who desire to specialize, and I suppose that in some instances almost 50 per cent of a graduating class has some such opportunities afforded them.

As doctors tend to settle in the larger communities, and those who locate in the larger communities tend to specialize, many different suggestions have been made which might encourage the recent graduate to locate in smaller communities. Physicians will continue to locate where there is the best demand for their services, and in medicine the law of supply and demand is still operative but not conformed to, for in many centers, especially where there are medical schools, graduates will begin practice in an overcrowded field and spend many lean years during which they are financially pinched and perennially discouraged. If on graduation they had moved to a center less bountifully supplied professionally, they would have made a livelihood much earlier and I believe that they would have advanced

further in their professional career, at least, they would have moved faster. If the plan to buy up marginal lands succeeds and these are transformed into parks and forest preserves, many doctors will be transported back into fairer zones and more specialists will develop than do at present.

Those who have been raised in small towns, judging from figures that have been compiled, have no great desire to return to small towns or less populous districts on graduation. It has been determined as a result of careful surveys that but between 2 and 3 per cent of those who come from communities of 1,000 or less returned to practice in areas of like population. In cases of students from towns of 5,000 or less, only 9 per cent returned, and the remainder located in the larger centers. Better opportunities to practice medicine as they have been taught, a worthy ambition, and higher financial rewards attract graduates to larger centers of population and the conditions and beliefs in the larger centers make specialization highly attractive to these graduates and, to restore the old order, the returns and conditions of life must be made more attractive.

The restoration of the doctor should begin in the medical school. What is it that a doctor should know? He should know how to make a diagnosis; he should know the natural course of disease and how to observe it and he should know what therapeutic measures should be instituted to meet the indication and when they are to be employed. During the past few years, emphasis has been laid on the laboratories. This was necessary because such rapid strides had been made in biochemistry, biophysics, bacteriology and the histologic examination of tissue. The laboratories have been obtained and now I believe more stress should be laid on the clinic. More clinical material is required, for in modern medical teaching the technic of diagnostic procedures is no longer simply demonstrated, but they are learned by the students and practiced by the student until these procedures can be used independently.

In teaching hospitals an endowment should provide the required number of free beds and the patient should be the patient of the student, who under strict supervision can assume charge. This is not possible under any scheme in which the patient pays full or half rates. Some have recently discovered that the pay patient can be used for teaching purposes and have tried to resurrect for expediency or because of exigencies of the economic depression a principle which died in the early eighties of the last century. I hope that the use of pay patients alone for teaching purposes cannot be even temporarily resuscitated.

The medical training which many students now receive makes the doctor dependent on hospitals, laboratory technicians, nurses, consultants and specialists. These distinctly influence the attitude of students and have a deciding influence in the development of specialism. The importance of physical examinations cannot be overemphasized, for the student of medicine who observes well, percusses well, hears acutely and feels intelligently has advanced far in the way of diagnostic ability.

With a due apportioning of diligence, the essentials of anatomy, physiology and pathology can be mastered. During the brief years of pupilage the details of the various branches cannot be grasped so that all cases can be accurately diagnosed and successfully treated. A deep knowledge of pathology is the foundation stone of diagnostic ability. Hamman, in the International

Clinics which he edits, makes some very pertinent remarks about the value of pathology. He says

In diagnosis the concept of tissue change predominates and the observation of function is of little value if it is divorced from the alteration of structure. It does happen that from the practical standpoint diagnosis leans more heavily upon anatomic changes than upon change of function, and our studies of function serve chiefly to allow us to decide accurately the character and extent of the structural lesions. It has been said that it is more important to gage the functional capacity of the heart and its power to recuperate than to decide to a nicety the character of the anatomic lesion. But the functional capacity of the heart and its power to recuperate depend in large measure upon the character of the lesion. This being true, the best way to study diagnosis is carefully to observe patients, from the data collected to draw inferences about the pathologic changes that are present and then to witness the verification or correction of these inferences at autopsy.

Physicians connected with large hospitals where autopsies are frequently performed are daily instructed but the doctor rarely has the opportunity to see post-mortems on the patients he has attended. This is a serious handicap to continued education. This brings up a discussion of how the continued education of the doctor is to be obtained, for this is one of the principal factors in his restoration.

During the past year, as President of the American Medical Association, it has been my privilege to visit many state societies and other medical associations and I have been struck with the earnest desire of those practicing in areas with small population and in centers far removed from one another to have demonstrations and discussions of the new things in medicine. Some of these men practice on what, I suppose, today, might be called marginal lands. But the desire for knowledge is just as active as is that of those practicing on more fertile soil. Some have suggested that the American Medical Association organize or sponsor some scheme by which parts of the Scientific Assembly might be shown, or some one sent out by the home office to carry the latest message. These doctors would willingly bear the expense. The work involved would be great but I think that an organization could be perfected which would provide educational facilities after graduation and provide for the patients ministered to by these doctors an extremely high quality of medical care. The lack of autopsies which make possible the check on diagnosis and the correction of errors would be hard to supply, and such knowledge cannot be imparted except by the clinical history with the citation of the changes in the cases on which the history is founded.

Every effort should be made to bring these practitioners into contact with hospital facilities. Unfortunately at the present time many of these men from the day they begin practice are excluded from hospital services, and I am quite sure that many of us would lose ambition and incentive if we had little or no opportunity to have free association with those whom not infrequently, we admire and have confidence in.

In a previous paper I have stated that cooperation should replace unrestrained competition. A ward should be set aside in general hospitals for the doctor of whom I am speaking, to which he might send patients requiring hospitalization. Such a ward could be properly supervised through the staff. The doctor would retain his patient. Work in such a ward would give him an opportunity to continue graduate work.

There should also be an adjustment of fees and the doctor should set a higher value on his services than he

does, because the public will hardly set a higher value on one's service than the doctor does himself. A change in fee schedule or an educational program might have such an effect. It is a rare occasion when a doctor will consent to a joint, itemized bill, and the financial status will not be improved until some such arrangement is made.

There may be considerable and honest diversity of opinion about the best method of medical practice. I believe that sometime in the not too distant future there will be a reversion to the old relation between patient and doctor when the doctor will make the examination and then decide what ancillary examinations are required, rather than act as referee, having all the data placed before him to be joined together. When the old methods return there will be more doctors and fewer specialists.

The medical profession is largely to blame for the development of specialism and the eclipse of the doctor, for during the past few years the patient has been educated to believe that the specialist is the last word, and as a result patients consult specialists first rather than the doctor. The licensing of specialists or the recognition of certain qualities which specialists should have will limit considerably their number and increase the number of doctors.

Surgically there are operations with which the doctor should be familiar. I shall name a few—appendicitis, hernia, empyema—which are emergencies. The doctor should be able to treat fractures, reduce dislocations and suture tendons and nerves. He should also have a sound knowledge of infections and their treatment. This is a limited therapeutic field and should be mastered. He should know his limitations as well as his abilities.

Osler in 1892 made a statement that applies with equal force forty-two years later.

In these days of aggressive self assertion when the stress of competition is so keen and the desire to make the most of oneself so universal, it may seem a little old fashioned to preach the necessity of humility, but I insist, for its own sake and for the sake of what it brings, that due humility should take the place of honor in the list. For its own sake since with it comes not only a reverence for truth, but also a proper estimation of the difficulties encountered in our search for it. More perhaps than any other professional man the doctor has a curious, shall I say morbid? sensitiveness to (what he regards) personal error. In a way this is right but it is too often accompanied by a cocksureness of opinion which if encouraged, leads him to so lively a conceit that the mere suggestion of a mistake under any circumstances is regarded as a reflection on his honor, a reflection equally resented, whether of lay or of professional origin. Start out with the conviction that absolute truth is hard to reach in matters relating to our fellow creatures, healthy or diseased that slips in observation are inevitable even with the best trained faculties that errors in judgment must occur in the practice of an art which consists largely in balancing possibilities—start, I say, with this attitude of mind and mistakes will be acknowledged and regretted, but instead of a slow process of self deception with ever increasing inability to recognize truth, you will draw from your errors the very lessons which will enable you to avoid their repetition.

Pellagra—Vitamin B, like vitamin B₁, occurs in yeast and cereal germ but it is also found in abundance in liver, eggs, milk, meat and green vegetables contain fair quantities. There is a good deal of evidence that the disease pellagra is in some way concerned with a shortage of this vitamin in the diet, although other dietetic faults probably contribute to the production of the disease.—Colwell S. J. *Vitamins in Clinical Medicine Practitioner* 132:15 (Jan) 1934.

THE OUTPATIENT CLINIC

J H J UPHAM, MD

Dean Ohio State University College of Medicine
COLUMBUS, OHIO

The free outpatient clinic has become a recognized part of the modern social welfare program. Started originally as a philanthropic movement for the relief of the ambulatory indigent sick, it has developed into an integral part of the entire hospital plan and lost its identity as a separate charitable entity.

At present there are four main functions of these clinics:

First, they materially reduce the number of hospitalization days in that they permit the discharge of many convalescing patients who are able to return to the outpatient department for dressings or other follow-up treatment, where they can be taken care of at much less expense than by continued residence in the hospital.

Second, through their service many patients are found who need hospitalization and are admitted to the hospital. While most of these enter the free wards, some surprisingly discover unsuspected funds for private rooms or pay wards. But whether they contribute financially or not, the more successfully treated and contented patients the better the reputation of the hospital in the community and the more generously is it supported. Hence this may be called the promotion function of clinics, and it is no inconsiderable one.

Third, there is the teaching function. It is rather the custom to classify hospitals as teaching and non-teaching hospitals, restricting the former qualification to those institutions connected with colleges or universities, whereas, as a matter of fact, all hospitals have, or at least should have, a very considerable educational influence not only on the medical profession but also on the public at large. Cushing in his address at the Ether Day Commemoration in the Massachusetts General Hospital, referred to the fact that hospitals in time acquire a definite personality just as do individuals. When one considers some of the famous hospitals of the world, such as the Hotel Dieu in Paris, the Allgemeines Krankenhaus of Vienna, the old Charité of Berlin, St. Bartholomews of London and, to come to this country, the Massachusetts General of Boston, Bellevue of New York, Blockley of Philadelphia and the Johns Hopkins Hospital of Baltimore, these names do not bring to mind thoughts of the great amount of charitable work done or the mass of patients treated but rather the long record of discoveries made of epoch making contributions to medical science and the development of leaders and teachers who have made medicine what it is today.

Every hospital should have before it such an ideal personality, and the closer it approximates that ideal the greater will be its reputation and its claim on the public for support, for it is being recognized that such hospitals in a community make for better doctors, raise the level of medical practice and elevate the standards of health in general. In this endeavor the outpatient clinics play a very definite part. The opportunities for self improvement and the gaining of medical experience in diagnosis and treatment of the wide variety of conditions met in these clinics have long

been recognized and appreciated by the ambitious younger practitioners, and staff appointments are eagerly sought. In the strictly teaching hospitals the teaching function of the clinic is even more emphasized. The medical student here is brought in direct contact with patients, he learns history taking, physical examination and treatment. In a well patronized and well organized clinic he will see a cross section of the medical practice of the community, which should be an excellent training for future practice. If possible, the student should be given the opportunity to follow patients from the clinic through their hospital care and back to the clinic after-treatment and thus obtain a complete picture of the case. Such teaching is invaluable and plays a very important part in the clinical years of the medical curriculum.

The fourth function of the outpatient clinic is its part in the social welfare program of today. There is no question that the relief of the indigent sick through these clinics is a very important part of this welfare program and not only is justifiable but fills an absolute need. On the other hand, criticism has arisen that the increase in number and growth in size of clinics has been so great that private practice of physicians has been encroached on and the economic status of practitioners has been injured. Doubtless there have been abuses in the past and still are in the present, in spite of earnest efforts made to eliminate them. Many clinics nowadays have well organized social service departments to investigate all those applying for treatment. This is necessary in justice not only to the practitioners but also to the community to avoid pauperizing those not really indigent. In these times, when many find it difficult to support an automobile or meet the instalments on a radio, the expense of medical treatment seems to many an unjust hardship, and often brazen effrontery and ingenious subterfuges are employed.

Continued vigilance and thorough investigation must be exercised to avoid this criticism. The habit of seeking relief is quickly established and hard to break. This is a danger to the self reliance and independence of the community, and the free clinics should not contribute to such dangerous social deterioration.

Practitioners of medicine have not a vested right in patients, but they do have a definite and necessary place in the social and economic scheme of life and a moral right to expect returns for many years of preparation for practice. They expect the competition of other practitioners and this has a wholesome effect in keeping up or improving the quality of service, but the giving of medical service by free clinics to those able to pay is unfair competition and every effort should be made to avoid it.

In recent years there has been a new development—the pay clinic. This has been a much discussed subject, and arguments for and against it have been often heatedly offered. It must be stated that my knowledge of these organizations is purely academic, and my remarks are intended to bring out discussion of the various aspects of the subject rather than to offer definite conclusions.

As it appears to me there are three main arguments for such clinics: first, as an aid to practitioners, second, as a measure of economic relief to individuals in moderate circumstances who may be able to pay a flat moderate fee for a complete physical and clinical examination but would be unable to pay for the various examinations and laboratory tests made separately,

third, the demonstration of methods of differential diagnosis in more or less obscure cases

Of these, the first seems to me the most valid, and theoretically it has many arguments for its justification. Many a conscientious practitioner, finding himself baffled by the unusual aspects of an individual case, would welcome the assistance of such a clinic. Otherwise he finds himself balked by the inability of the patient to pay for the various diagnostic tests required, or, if they are undertaken, the finances of the patient are exhausted and there is nothing left for the practitioner who is to carry on the real burden of treatment. This arouses a certain resentment, a sense of injustice, which is disturbing to even the most judicious minds, and in the long run both the good name of the practice of medicine and, especially, the patients suffer materially.

Theoretically, therefore, such a clinic would have a strong claim for its justification if it accepted only patients of the economic status described, referred by practitioners for aid in diagnosis, and referred them back to the practitioners for treatment. If such a plan could be carried out with the close cooperation of practitioners and the clinic it would undoubtedly work out to the great advantage of the patients, raise the standards of practice and enhance the reputation of the medical profession in general.

Unfortunately, this ideal condition does not seem always to be present. There are charges of lack of cooperation on both sides: practitioners complain of patients lost to them after being sent to the clinic and the clinics that the suggested treatments are not followed—with probably some truth on both sides. Patients impressed with the quality of service received in a clinic may insist on seeking treatment with the complaint, perhaps true, often not true, that their physician has failed to follow the recommended therapeutic measures.

Again, they may bring friends or acquaintances directly to the clinic for diagnosis.

It calls for constant vigilance, tact and diplomacy on the part of the management of the clinics, with careful supervision of the personnel, to meet these embarrassing situations.

It is one thing if they are frankly commercial institutions, with everything grist that comes to their mill, because then they can be properly evaluated, and they stand or fall according to the quality of the service rendered and the complaisance of the medical profession. It is quite another if the clinics claim altruistic motives or seek a place in the teaching program. In these instances, all the force of professional traditions and ethics should be invoked to keep their activities within the strict line of their avowed purpose of improving the practice of medicine. Only as they do this will they be justified in the eyes of the profession.

Secondly, there is the matter of meeting the economic needs of patients in moderate circumstances. The question immediately arises: Is this necessarily a responsibility of the medical profession? It is rather trite to say that everything is relative, but has not the importance of the relative importance of health and medical treatment rather been lost sight of in all this discussion?

In days gone by the family budget usually provided that of every dollar a certain amount would be allotted for rent, taxes, food, light, heat, clothing and other definite necessities. Thrifty families would see that

there would be a part left, even if small, for savings or provision for "a rainy day." In this there was thought of the possibility of illness and provision was made for it. The obligations of medical treatment were part of the planning as a possible necessity to be taken care of from this optional part of the dollar. In the last ten or fifteen years there has been an unrivaled organized commercial drive on this portion of the family budget. Luxuries such as automobiles, radios and electrical domestic appliances have come to be looked on practically as necessities, and especially since they are so attractively (seemingly) offered on the instalment plan of purchase the habit of saving has become a vanishing virtue. The thought of paying for illness seems indeed a hardship if it entails the giving up of an automobile, a radio or an electrical refrigerator. Do not the continued harping on the high costs of medical care and the efforts made to reduce these costs by lowering the professional charges encourage this state of mind of the public? Is there not danger that this move will foster the idea that all medical charges are unjust and should be taken care of by the state?

It is true that the costs of medical care have increased very materially in the last generation through better means of diagnosis and treatment, substantially to the advantage of the public. It is my belief, and that of many others who have given this matter thought, that in the general desire for more exact diagnoses there has been a trend to overemphasize the modern and often expensive laboratory and technical tests at the expense of the older methods of physical diagnosis and simple clinical tests. This necessarily has contributed somewhat to the increased costs, which could be reduced, at least to some extent, if students were trained more thoroughly in inspection, palpation, percussion, auscultation and simple laboratory tests and to use judgment when appealing for further help when it is actually needed. I would not appear to disparage the modern laboratory or technical accessory methods, in very many cases they are extremely helpful, even essential to correct diagnosis and treatment, but in some at least I believe they have been utilized unnecessarily, to the financial disadvantage of the patient, by failure of the practitioner to exercise proper skill in simpler means.

There is another point to be considered in this question of meeting the economic needs of the patient in moderate circumstances, and that is, What is the definition of moderate circumstances? If it includes that large group today that finds it difficult or at least finds itself hampered to pay for regular medical charges because of the desire for the luxuries so enticingly offered, I do not feel that this argument for the establishment of such clinics can be justified to the medical profession. On the other hand, every practitioner comes in contact with patients who need, at times, expert laboratory or technical means of diagnosis for whom the regular charges would be a hardship, and therefore the answer to the foregoing question should best be left to the family physician, than whom no one is in a better position to judge of the financial status of his clientele. This again would tie up the operations of the pay clinic with the practitioner to the mutual enhancement of medical practice and the best interests of the patients needing the services of such clinics. The closer this cooperation and the more strictly this policy is adhered to, the wider the recognition that will

be given to such clinics and the more their existence will be justified to the public and the medical profession.

The offering of the service of such clinics unreservedly to people of so-called moderate circumstances, however, unvouched for by their attending physicians, without restrictions, does not appear to me to be economically or professionally justifiable.

TEACHING VALUE OF THE PAY CLINIC

The curriculum of a modern medical college has become a very complicated one, and every proposed addition must be carefully scrutinized and evaluated before it can be adopted. For the average student the present course is a burdensome one, and with the great increase of medical knowledge and the development of medical specialties the danger has been recognized that in the effort to cover all the field of medicine in four years students would dissipate their energies and could at best acquire a superficial knowledge. This objection is met, at least in part, by the generally adopted plan of thorough instruction in the basic sciences in the pre-clinical years, followed in the clinical years by the general instruction in diagnosis and treatment in all departments of medicine so as to equip the average student with as broad a foundation as possible for general practice or for any specialty he may subsequently elect.

No student on graduation is fitted to engage in surgery, ophthalmology, dermatology or, strictly, internal medicine, and the necessity is recognized that further postgraduate work and often long training is essential before so engaging. There is no question as to the teaching value of demonstrating the differential diagnosis in obscure cases. Does not this type of teaching, however, fall into the category of advanced work and so really belong to postgraduate instruction?

Also is there not danger of distorting the value in the mind of medical students, not thus far familiar with the general incidence of these types of cases, and of over stressing the laboratory and technical methods of diagnosis already under a certain amount of criticism? Is it not more in line with the plan in other departments of teaching to drill thoroughly in the general methods of diagnosis and treatment, illustrating as thoroughly as possible with typical cases, so as to meet as far as can be foreseen the needs of the young practitioner, and leave the more obscure and rarer cases to postgraduate instruction?

These are questions which demand careful consideration when one seeks to evaluate the teaching value of the pay clinic, especially in connection with medical colleges, but to my mind such clinic teaching appears to be in the same category as advanced teaching in the specialties and thus belongs to postgraduate instruction rather than in the regular college curriculum.

SUMMARY

The operation of pay clinics is beset with so many difficulties and the criticisms that have arisen are so numerous that it must be said that many in the medical profession are very dubious as to their place in medical practice. Their many possibilities for good can be recognized, and their existence justified to the medical profession, according to the degree in which they cooperate with practitioners in improving medical practice and refrain from unfair competition.

Their teaching place would appear to be that of advanced medical instruction.

327 East State Street

THE IMPORTANCE OF INTRODUCING PSYCHIATRY INTO THE GEN- ERAL INTERNSHIP

FRANKLIN G. EBAUGH, MD
Director, Colorado Psychopathic Hospital
DENVER

The final report of the commission on medical education¹ emphasizes the general need for revision of medical training by (1) bringing clinical methods into closer relation with preliminary sciences and with anatomy and physiology, (2) permeating all teaching with the idea of prevention and demonstration of its methods, (3) emphasis on the importance of the psychologic aspect of medicine and the treatment of the person rather than the disease, and (4) recognition of the concept of medicine as a social agency. Each of these recommendations will be furthered if the principles of psychiatry can be applied more generally through the medical course and in intern training.

I shall discuss the importance of psychiatry as a part of the intern's training from the following points of view: (1) the present status of psychiatry in medical school teaching and the attitude of the student toward it, (2) the part psychiatry plays in the present training of interns, (3) the methods of insuring a more adequate psychiatric training for the future intern, and (4) general recommendations and summary.

THE PRESENT STATUS OF PSYCHIATRY IN MEDICAL SCHOOL TEACHING AND THE ATTITUDE OF THE STUDENT TOWARD IT

Recent studies conducted by the National Committee for Mental Hygiene² indicate considerable inadequacy in the teaching of psychiatry, although much good work is being accomplished and many changes are now being made to meet better the requirements of this phase of medical education. For instance, it was found that the teaching of psychiatry was considered to be reasonably complete in thirteen grade A schools, while 42 per cent of the total group visited have not yet created clinical psychiatric facilities to be used in the general teaching schedule. Furthermore, there appears to be a lack of psychiatric teaching personnel in approximately 85 per cent of the schools visited. Many gaps and deficiencies were found in the present psychiatric curriculum, especially in the important preclinical years. This lack was further accentuated in terms of a general neglect of the social sciences during the college course. It can readily be seen, therefore, in a discussion of psychiatry as a part of the general internship, that a great deal must be done to improve undergraduate psychiatric teaching. Since the completion of this appraisal by the National Committee for Mental Hygiene, there has been encouraging evidence that approximately half of the medical schools are in the process of developing more adequate teaching facilities for psychiatry.

In many schools psychiatry is being accepted as a major division of the medical curriculum. The attitude of the deans of each medical school in relation to the studies mentioned was considered most favorable.

From Division of Psychiatric Education, National Committee for Mental Hygiene.

Read before the Annual Congress on Medical Education, Licensure and Hospitals, Chicago, Feb. 13, 1934.

for the future development of psychiatry. Their main criticisms concerned the past isolation of psychiatry. The main causes of this isolation of psychiatry I consider to be in relation to its general neglect in medical thinking and practice. In fact, many physicians and clinicians uninitiated to psychiatric points of view may actually be defensive toward psychiatry and impart this attitude to their students. The breakdown of overspecialization and overdepartmentalization and the presentation of psychiatry as a part of all fundamental medical training, with the development of liaison and correlation activities with other departments are now playing important roles in improving this situation. Psychiatry has been isolated also in terms of the institutional aspects of psychiatric work and the unfortunate tendency in some schools is to present the subject in terms of asylum diseases and end products. Such a presentation could not be inductive to the development of interest on the part of the student. This will be corrected by the development of well equipped psychiatric departments in general hospitals bringing psychiatry under the same roof with general medicine and by greater utilization in undergraduate and graduate teaching schedules of the existing psychopathic hospitals. Other attitudes toward psychiatry are emotionally determined, that is, the mistaken views that psychiatric terminology is considered too difficult or unintelligible and that psychiatry deals excessively with sex problems. Furthermore, the situation is distorted by the impression that psychiatrists in general neglect physical studies and that this field has attracted unstable individuals.

One cannot deny that the term "health" embraces a much broader concept and meaning than it ever has before. It was formerly felt that everything up to the eyebrows belonged to the consideration of the physician, while all above them was relegated to the cleric and philosopher. There has been a progressive tendency to get away from a mind and body entity and to accept the individual as a whole, a complex but unified singleness functioning as a "person," subjected to situations that produce disease demonstrable as such and expressing themselves in disturbance of organ behavior or to still other situations producing maladjustments resulting in behavior disorders of the entire organism, not merely a particular part of it. No physician need go far with his imagination to appreciate the clear-cut effect of so-called mental phenomena on the physical being. If he does, let him ask himself why he keeps from the patient injured in an automobile accident the fact that his partner was killed outright, or again, why does he insist on the most cheerful atmosphere for his convalescent's recuperation?

The etiology of the more common medical conditions—arteriosclerosis, angina pectoris, exophthalmic goiter, chorea, urticaria, hay fever and the like—present as etiologic possibilities "psychogenic factors." To the intern without psychiatric attitude and appreciation how is the term "psychogenic" going to be any more than an eleven letter word meaning "to have its origin in the mind?" He becomes cognizant after not too many weeks in a medical service that he is unable to find "pathology" to account for all symptoms and complaints presented. The pictures are not by any means "textbook," and chest thumping fails to reveal the mysteries surrounding the strange case. What then? Unless he is willing to consider the individual in his entirety, to evaluate his life situations and emotional responses in exhaustive investigative pursuit he is of

little service to his patient and may become defensive regarding his lack of psychiatric knowledge and scoff and belittle this field. Later his patients may leave him and go in desperation to the quack.

There have been and are, to be sure, psychiatric services in rotating internships. It is the unproductiveness of these services that has kept many present-day hospitals from offering contact with problems of mental health. Heretofore they consisted of dark, gloomy, barred corridors apart from the general wards where patients, attired in peculiar garb, sat lined against the wall for ten hours each day. Even today restraint is used in some of these wards. The intern comes, asks about voices, makes tests for "waxy flexibility," does a tube feeding and, with a feeling that he shares in a strange mysticism, flourishes the diagnosis "dementia praecox" across the record. I am not advising such intern training.

One chap who was entering a psychiatric service was asked by an associate what he was going to do with his "Osler" now that he was leaving medicine. This not uncommon attitude permeates the thinking of those not acquainted with modern psychologic medicine. The man coming into a psychiatric service must bring with him every bit of medical knowledge. His domain of concern becomes much broader and less mechanistic. He brings order and reason into his methods of approaching clinical problems rather than the too great dependability on instruments of precision. The following are some verbatim statements made by interns in a general hospital that has no psychiatric service included in the rotating internship. These statements were made to the consulting psychiatrist.³

I've got a patient who is running a high BMR and I just can't seem to get it down. She's on large doses of Lugol's solution and luminal, but every time the surgeon comes around he scares her by his gruff manner and the basal goes up so that we can't operate and then we have to start all over again. I wish he would stay away until we are ready to operate. Perhaps there is something emotional wrong that we could correct, but I don't know how to start.

I have a case that came in with a pain in his stomach that was sent in as an ulcer. When he started talking about wanting to buy ten farms and started fighting with the patient in the next bed, I knew there was something wrong, but didn't know where to begin. After consultation we knew that he had general paresis. In my school we didn't learn much about mental examination and of course we have none here.

I have got a case up on pediatrics. The kid cries all day and he has fainting spells. I am at a loss to know what to do. His father is a mean old cuss and his mother coddles him like an infant, but I can't find anything wrong with him.

We are all ready to operate on that girl for adhesions around the appendix but the chief surgeon can't make up his mind. She had an appendectomy two months ago but it didn't do her any good. She's a typical case in some ways but then there's so many other complaints—headache, dizziness, numbness of the fingers—and she seems pretty scared about it all. Maybe her personality has something to do with it.

How do you get these patients to talk to you? I have noticed the effect of the unburdening of their troubles but I just can't seem to get next to them. Maybe it's because I don't know where to start. Perhaps it's because I've had little or no psychiatry in school. Have you any books I can read on psychiatry? I know that I am going to get some of these patients when I finish my internship and I would like to know what to do. Of course, you can always give them luminal but that isn't always a panacea.

One might go on almost ad infinitum with arguments for a psychiatric service in the rotating internship, but

3 I am indebted for this material to Drs. Clarke H. Barnacle and Chester L. Reynolds of the Colorado Psychopathic Hospital staff.

I would stop with saying that it would broaden the intern's concept of "pathology", impress him with the tremendous complexity and interrelation of mental and nonmental factors of the human organism, revise his attitude toward mental disease as treatable processes offering hopeful prognosis, organize his own thinking to more orderliness, give him understanding to the great number of patients who will come to him for whom psychiatric intelligence is indicated, and finally but by no means least, enrich his own appreciation and joy of life

My previous experience, especially at the Philadelphia General Hospital, indicates that intern participation in psychiatry for a two months period is most practical and useful in the training schedule and is well appreciated by all groups and a recent communication from Dr. Turnbull, superintendent of the Philadelphia General Hospital, indicates that this point of view has continued during the past decade

THE PART PSYCHIATRY PLAYS IN THE PRESENT TRAINING OF INTERNS

At the present time there are, according to the Council on Medical Education and Hospitals of the American Medical Association, 7,357 interns serving in registered hospitals.⁴ Of these, 6,204 interns are serving in hospitals approved for internship by the American Medical Association. In a list of 689 hospitals approved by the American Medical Association there are eighty-five reporting departments for mental disease and sixteen hospitals definitely affiliated for psychopathic service, with an internship of 1,601, or 20.6 per cent of the total number receiving psychiatric service in approved hospitals

In the studies I conducted for the National Committee for Mental Hygiene there were fourteen psychopathic hospitals for institutes utilized by eighteen schools for teaching. Opportunity for intern training, however, was not given by all these hospitals although the teaching schedules in most centers arranged for valuable preparatory training in psychiatry. In addition, there were psychopathic wards in twenty-five hospitals which were utilized by twenty-six schools for instruction. Intern training was given in only thirteen of these hospitals

In addition, intern participation in psychiatry is made possible in many state hospitals. In many instances the opportunity for equivalent training is afforded during the senior year or through clerkships in the vacation months. This may be illustrated in the excellent schedules provided by Boston University, Tufts College, the University of Vermont and the University of Kansas. The students interviewed from these schools on the whole indicated a reasonable inoculation with the psychiatric point of view with basic knowledge pertaining to psychiatry as a phase of all medicine. One can anticipate in the future greater utilization of the state hospitals for intern training, preferably given following a general rotating internship, as is now utilized in the New York state hospital system. The development of well organized reception services in state hospitals such as is illustrated at the Boston State Hospital and St. Elizabeth's Hospital, where an excellently equipped medical and surgical unit is available, indicates possible expansions in the psychiatric training schedule with affiliation with the nearby general hospitals. I should not say, with the rapid changes now taking place in

developing psychiatric facilities, that there will be a dearth of places for recent graduates to go for psychiatric training

It is not my purpose here to discuss psychiatry as a specialty. That is a matter of postgraduate education and is being provided for through resident training and fellowship training. Here again is seen the great stimulus offered by the Council on Medical Education and Hospitals of the American Medical Association. The recent organization of the American Board of Psychiatry and Neurology indicates that rapid changes and improvement in personnel and teaching may be expected in the near future, which may be reflected in further intern participation in psychiatry

METHODS OF INSURING A MORE ADEQUATE PSYCHIATRIC TRAINING FOR THE FUTURE INTERN

In the studies that have been made to date there appears to be a reasonably unanimous opinion that psychiatry should take a fundamental place in the intern's training. There are numerous organization difficulties and undoubtedly many local situations at the present time which make it impossible to allot time to psychiatry in the period of twelve months' training. To the interns themselves this appears to be only too brief for covering medicine and surgery and their component problems. Psychiatry, however, can be introduced in many hospitals through an active consultation service in which the intern will have an opportunity for individual or group discussions concerning ward and outpatient clinic cases. The present development of liaison work with the departments of medicine, as noted in the following schools makes this a possibility: the University of Nebraska, Harvard University, Stanford University, Cornell University, Columbia University, Yale University, McGill University and the University of Colorado. The work of Dr. Noble at Yale is especially noteworthy in this connection, where liaison work with psychiatry is now active to the extent that ward rounds are made by the psychiatrist in the medical, surgical and pediatric departments. This work has been well received by the interns and residents at the New Haven Hospital and it is reported that it is now accepted as a fundamental part of their teaching schedule. Liaison work in connection with the department of pediatrics has developed in the University of Rochester, the University of Pittsburgh, the University of Buffalo, the Johns Hopkins University, the University of Cincinnati, the University of Nebraska, Cornell University, Columbia University, McGill University, Yale University and St. Louis University. The most outstanding example in this country is that at the Johns Hopkins University, where Dr. Leo Kanner, trained under Adolf Meyer, assumed the responsibility for a psychopediatric clinic at the Harriet Lane Home and conducts seminars and conferences with the interns on the straight service there. Active psychiatric consultation service in the general hospital has already proved an important method of introducing psychiatry into the intern schedule. Furthermore, general hospitals without psychiatric ward facilities can do much to further the training of interns through including child psychiatry in the outpatient clinics

Another possible method of introducing psychiatry is to increase the period of intern training from twelve months to eighteen or twenty-four months, allotting from two to four months to psychiatry. This should prove satisfactory and enable adequate representation

⁴ Medical Education in the United States and Canada. J. A. M. A. 101: 677 (Aug. 26) 1933

of this basic field I would strongly recommend that there should be greater utilization of the existing psychopathic hospitals for intern training. At the present time it is the exception for these hospitals to be used in the general intern training, although several offer excellent straight internships or house officerships, such as is shown at Phipps Psychiatric Clinic. It is possible, however, to utilize these institutions more for the general intern or at least for clinical clerkships during the senior year, which frequently may meet the need satisfactorily. Rappleye has offered another suggestion in his discussion of the large amount of time spent in surgical training, especially in the operating room, during the rotating internship. He feels that this time could be decreased, since surgical training and operating technic can be given in the training years required for this specialty. I would recommend that some of this time be given to psychiatry. If facilities are not available, the outpatient service and medical wards abound with opportunities for encountering various types of mental disorder. This work, of course, should be given by trained psychiatrists.

Adolf Meyer⁵ has recently given an excellent exposition of the apprenticeship method of graduate training in psychiatry. This should be established early during the internship. Rappleye wisely speaks of standards and not standardization in discussing the educational program of the internship. Since the internship is one of the most important parts of the basic preparation for the practice of medicine, it should reflect the changes that are now occurring in psychiatry as a phase of medical education. From this point of view, the content of the intern training in psychiatry over a minimum period of at least two months, preferably four, should cover the following, with the main objective of enabling the physician to recognize the rank and file of psychiatric problems that he will encounter in both later general and special practice. Every physician should know how to conduct a systematic mental examination for the detection of emotional disorders, mild delusional trends, neurotic developments and the like. This may be considered just as important for them as the ability to do a complete physical examination.

The psychobiologic point of view advocated by Adolf Meyer should be utilized. The following is considered a definition of psychobiology. Psychobiology is that science which deals with the individual as a whole, as a complex but unified entity functioning not as mind and body but as a unit expressing mental and non-mental behavior, these components are so interrelated and interdependent that they cannot be separated one from the other. As a "science" one presupposes that psychobiology shall submit itself to those laws of science set out in Koch's postulates and that as such the behavior of this organism may be scrutinized and best studied as any experiment, an "experiment of nature," for the conditions under which the behavior develops, its mode of working, and its course and modifiability. It is the level of psychobiologic functioning that one implies when speaking of mind, consciousness, thinking, or behavior with mentation.

In terms of the average rank and file of psychiatric patients encountered by the physician, the experience and clinical contacts of the intern should center around the following:

1 The minor psychoses, or the psychoneuroses. These include, in accordance with previous studies

made, between one third and one half of the problems of general medicine in which detailed, exhaustive studies from the point of view of the organic manifestations are not fruitful. A convenient classification of the psychoneuroses is that given by Culpin.

(a) The anxiety states which are considered to be the most frequently encountered are those in which the symptoms are grouped around a central core of anxiety and anxious expectation. The main symptoms are expressed in the anxiety attack and panic with fear of death, fear of insanity, fear of stroke with accompanying disturbance of one or many bodily functions—heart action, respiration, vasomotor innervation and the like. These patients may commonly complain of difficulty in breathing, precordial pains, drenching sweats, and gastro-intestinal upsets, and it is important to differentiate these anxiety attacks from organic conditions. The relationship of the genesis of the anxiety states with actual life experiences of the patient, frustrations in connection with many of the major life problems centering around parent-child relationships, school relationships, vocational, marital and sex maladjustments, religion and recreational adjustments is the most important and practical aspect. Furthermore, it does not help to remove the thyroid gland for such a patient, or to carry out a series of operations, which are found to be so frequent in all medical and surgical services. The diagnoses of part illnesses, such as gastric neuroses, cardiac neuroses and neurocirculatory asthenia, have little use in covering up the lack of understanding of the origin and treatment of these problems.

(b) The second group of the psychoneuroses comprises the substitutive disorders in which there are hysterical symptoms, usually expressed as motor phenomena, sensory phenomena or mental phenomena, such as shown in hysterical amnesic states and convulsive states. Dr. Barnacle, working in the Colorado General Hospital outpatient clinic, found that the psychoneuroses were by far the most frequent problems referred for him to study. He found that there was considerable interest and desire on the part of the younger staff members to treat these patients from every point of view.

(c) The obsessive states make up the third group. 2 The major psychoses. Among the problems of the major psychoses, the content of psychiatric training should provide experience regarding

(a) The organic reactions in which one can especially see the importance of the recognition of early signs of dementia paralytica—irritability, bradyphrenia, shown in changes in character and disposition of the patient, loss of weight, sleep disturbance—which may antedate the more profound classic signs of this disorder commonly present in the end stages. The clinical problems of malaria therapy of these patients and the essential follow-up procedures provide the intern with methods and social points of view that he can utilize generally.

(b) In a consideration of the disorders of the physiologic support for the brain through toxic disturbances, trauma, metabolic disturbances and the like, there is an irreducible minimum of knowledge that every medical man should have.

(c) The manic depressive psychoses are of very practical clinical importance in terms of early recognition as well as in relation to the problem of suicide,

⁵ Meyer, Adolf. Preparation for Psychiatry. Arch. Neurol. & Psychiat. 30: 1111 (Nov.) 1933.

which after all constitutes one of the most important social medical problems of today. The biologic equivalents of depression shown in fatigue, a sense of heightened effort, general retardation of energy output, loss of weight, sleep disturbance, and constipation should be promptly noted by every medical man as well as the existing type of mood disturbance. Furthermore, every medical man should realize the value of early therapy in the depressive group. Many problems are associated with states of elation and excitement, which will depend on early recognition to safeguard the patient properly from all points of view—social, medical and legal.

(d) There should be a reasonable understanding of the more sweeping personality distortions shown in the schizophrenic disorders, in which the patient shows projections of topics of personal sensitivity or dominant subjects to the environment and develops ideas of reference, delusions and hallucinations. It is in this group that are found more highly personal reference and significance in terms of the life experience of the patient.

(e) The paranoid group of psychoses present a great medical responsibility, especially in relation to early hospitalization.

(f) Likewise, the problem of mental deficiency and the constitutional deficit states should be recognized by the general practitioner.

The importance of the physician's attitude in approaching the patient, the development of rapport, reeducation procedures, and desensitization of the patient with the purpose of developing insight and understanding regarding the origin and nature of his symptoms, both physical and mental, cannot be over-emphasized in the intern's training. Opportunity for such training should be offered in a general internship. Medical education is a continuous process and the physician's experience in psychotherapy is increased from year to year in terms of his clinical contacts.

GENERAL RECOMMENDATIONS AND SUMMARY

1 Psychiatry should be represented in the general internship as part of the basic preparation for the practice of medicine.

2 Such participation of psychiatry in straight, rotating and mixed internships is now possible in most hospitals through

(a) Combined clerkships and internships and service in state hospitals during the summer months

(b) Active psychiatric consultation service in both ward and outpatient departments

(c) Liaison work between the various departments, especially with medicine and pediatrics

(d) The allotment of definite time for psychiatry, preferably from two to four months in rotating schedules

There should be greater utilization of the well equipped psychopathic and state hospitals, whereby affiliated schedules can be developed for intern training.

3 At the present time less than one fourth of the 7357 interns now in training have the benefit of psychiatric training. In general, these psychiatric services are well appreciated by the intern and accepted by the staff and administrators of these hospitals as an essential part of the basic training.

4 Psychiatric training in the future should be considered as a requirement for licensure. This will be a great educational step forward in protecting the public from the quack and further emphasizing the importance

of the psychologic aspect of all medicine as well as furthering greater cohesion and correlation between the various fields of medicine.

5 Introducing psychiatry through the general internship will be a great impetus to the changes now taking place in undergraduate and graduate psychiatric teaching schedules. It should play a role in breaking down the tendency for immature specialization in various fields and in the acceptance of psychiatry as a fundamental phase of all medicine.

4200 East Ninth Avenue

DYSMENORRHEA RELIEVED BY RESECTION OF PRESACRAL SYMPATHETIC NERVES

ALFRED W. ADSON, M.D.

AND

JAMES C. MASSON, M.D.

ROCHESTER, MINN.

Our satisfactory results in the treatment of peripheral vascular disease by sympathetic ganglionectomy and trunk resection have encouraged us to carry out investigations of diseases resulting from dysfunction of the sympathetic nervous system. The present report is a review of six cases of dysmenorrhea relieved by section of the presacral nerve, the operation described by Cotte in 1924.

HISTORICAL DATA

Jaboulay¹ is credited with making the first attempt to relieve pelvic pain by interrupting the afferent pathways in the sacral sympathetic chain. Ruggi² contributed to this investigation by performing abdominal sympathectomy for functional disturbances of the female genital organs, and he advised resection of the utero-ovarian plexus by the transperitoneal route. The results of Jaboulay's and Ruggi's operations were only partially successful, some patients were relieved, some were partially relieved, and others had recurrence of pain. Leriche³ introduced periarterial sympathectomy of the internal iliac artery as a means of relieving pain in cases of functional dysmenorrhea. This procedure was adopted and used by Cotte,⁴ Hallopeau⁵ and Michon.⁶ Cotte (1925) introduced the operation of resection of the superior hypogastric plexus (presacral nerve of Latarjet,⁷ or the prelumbar nerve of Elaut⁸), for functional dysmenorrhea, and reported excellent results. Since Cotte's operation is the more easily performed, it has been substituted for periarterial sympathectomy of the internal iliac artery. The same surgical

procedure of presacral resection of nerves has been employed by Learmonth⁹ and others, in the treatment of cord bladder and painful bladder, and in Hirschsprung's disease, since the superior hypogastric plexus (the presacral nerve of Latarjet) contains nerve fibers conducting vasomotor responses to the vessels of the bladder, sigmoid and rectum, contracting impulses to the internal sphincter of the bladder and rectum, inhib-

Fig 1—Left elevation of presacral nerves as they cross the bifurcation of the abdominal aorta. Right method of resection of presacral nerves.

ing impulses to musculature of the bladder and rectum, and contracting impulses to the urogenital trigon and afferent pain fibers.

Anatomy—Elaut stated, after a review of fifty cases, and of the anatomic works of Hovelacque,¹⁰ Latarjet Bonnet and others, that the presacral nerve has its origin in the aortic plexuses situated between the superior and inferior mesenteric arteries. The two nerves are arranged in parallel bundles associated with an oblique anastomosis running across the aorta to rejoin its partner on the opposite side (fig 1). The bundles sometimes run together on the anterior wall of the aorta for a distance of 1 cm, where they disunite into separate groups. To the intermesenteric nerves of Petit-Dutailis and Flandrin,¹¹ postganglionic lumbar sympathetic fibers are added, so that at the level of the inferior mesenteric artery the intermesenteric nerves divide into two distinct bundles: (1) the inferior mesenteric plexus running along the artery itself, and (2) the bundle continuing straight down on the anterior wall of the lower part of the aorta and below. This is the so-called plexus hypogastricus superior of Hovelacque and consists of two main bundles. In both bundles, several fine branches may be detected and separated from their neighbors. The two main bundles are parallel at a distance of about 1 cm from each other but have a definite tendency to join so as to make a distinct branch. Elaut stated that an incongruence arises in the description of Latarjet and Bonnet, since these authors make a distinction between the two sympathetic chains, the lateral vertebral chain and the prevertebral chain. Although the aorta divides into the common iliac arteries, the prevertebral chain does not divide in like manner. Most of the nerve elements assemble to form

a flattened and irregular cord composed of compact fasciculi united by short anastomosis and dense connective tissue. This particular nerve has been called the "nervous uterus magnus" by Tiedemann.¹² However, since this nerve bundle contains fibers to organs other than that of the uterus, it is usually called the presacral nerve. It enters the pelvis over the bifurcation of the aorta, crosses the left iliac vein, rises over the prominence of the promontory and is stretched on the anterior surface of the sacrum. For a distance of from 4 to 6 cm after it reaches the pelvis, the presacral nerve separates to form the two hypogastric nerves. Elaut stated, following his anatomic investigation, that the use of the term "nerve" in describing a plexus of the presacral nerve is inappropriate, since there are so many variations and the arrangements of the fibers in the nerve really form a plexus and therefore should be called the superior hypogastric plexus of Hovelacque. He further stated that the triangular mass of nerves situated between the common iliac arteries on the promontory receives a series of secondary connections from the inferior mesenteric plexus which lies within the pelvic mesocolon, which in turn lies at its left, and from the last ganglion of the lumbar chain. The presacral nerve (superior hypogastric plexus) in reality forms a trigon, which is situated between the common iliac arteries posterior to the peritoneum and on the anterior surface of the sacrum. It is readily exposed by incising the peritoneum in the median line from the bifurcation of the aorta downward for a distance of 8 cm (fig 2).

A few nerve filaments from the superior hypogastric plexuses course along the common iliac artery. The inferior hypogastric nerves that are a continuation of the principal bundles of fibers from the superior hypogastric plexus course obliquely from above downward in the lateral rectal space. They then follow the internal

Fig 2—Left diagram of superior hypogastric plexus (presacral nerve) illustrating its position and relationships of the nerves. Right the portion resected.

iliac artery and give off branches with accompanying branches of these arteries, while a group of fibers from the inferior hypogastric nerve terminates in the musculature of the urogenital trigon, bladder and rectum. However, before doing so they pass through a ganglionic mass known as the hypogastric ganglion, which is situated in the superior pelvic space between the peritoneum and the fascia covering the levator ani muscles.

A secondary plexus forms on the anterior surface of the rectum, just posterior to the uterus and vagina and becomes intimately connected to the uterosacral ligaments

Uterus—Fontaine and Herrmann,¹³ in a review of the sympathetic innervation of the uterus, tubes and ovary, made the following statement: "The nerve fibers in the wall of the uterus are derived from the great plexus of Frankenhauser,¹⁴ which is situated on each side of the body of the uterus and the broad ligament. These plexuses are made up of fibers from both the hypogastric and sacral plexuses. The nerve fibers in the wall of the uterus are distributed mainly in the uterine musculature. Certain of the older investigators maintain that nerve fibers also terminate in relation to the uterine mucosa, but according to Kuntz¹⁵ most data now available do not support this view. It is Kuntz's belief that in all probability true ganglion cells have been observed in the wall of the uterus, which probably have become displaced from the ganglions in the uterovaginal plexus during the course of development."

Fallopian Tube—The fallopian tube is supplied by unmyelinated and myelinated fibers derived from the ovarian plexus. Kuntz stated that the bundles of nerve fibers penetrate the wall of the tube and give rise to branches, which are distributed to all layers except possibly the epithelium of the uterus.

Ovary—The ovary derives its nerve supply mainly from the ovarian plexus, which arises from intermesenteric and renal plexuses and follows the ovarian artery throughout its entire course. Hovelacque stated that three fibers arise from the middle of the renal plexus to join the ovarian plexus. The ovarian plexus enters the suspensory ligament of the ovary and divides into an external tubular branch, which supplies the fallopian tube and one or several internal branches that go to the hilus of the ovary. Five or six terminal filaments of the external tubular branch course through the broad ligament and reach the lateral border of the uterus.

Parasympathetic Nerves—Parasympathetic fibers arise from the visceral branches of the second, third and fourth sacral nerves. These fibers with cortical spinal nerves transmit to and receive impulses from the pelvic organs. They are intimately associated with the sympathetic fibers and take part in the plexiform arrangement about these organs.

Sympathetic Afferent Nerves—It has been generally assumed that all postganglionic sympathetic neurons are efferent fibers, but in the light of clinical results in the treatment of peripheral vascular and painful lesions of the extremities by sympathectomy, and the results obtained in the treatment of functional dysmenorrhea by resection of the presacral nerves, it might be assumed that afferent pain fibers are intermingled with the postganglionic fibers and reach the dorsal ganglion of the spinal roots by an antidromic course through the white ram communicantes.

The Physiologic Function of Pelvic Nerves—Fontaine and Herrmann stated that the hypogastric plexus exerts a vasoconstrictor action on the vessels of the

internal genital organs, whereas the parasympathetic nerves exert a vasodilatory effect. The sympathetic nerves inhibit the secretion of the genital glands and the parasympathetic nerves stimulate the glands to secretion. The exact control of the motility of the uterus is still unknown. Langley and Anderson¹⁶ demonstrated that the center of the rabbit's uterine contractions is situated between the tenth dorsal and the second lumbar segment of the spinal cord. Dahl considers the sympathetic fibers as the exciters, and the parasympathetic fibers the inhibitors of uterine contractions.

The Pelvic Sympathetic Nerves in Relation to Menstruation—Resection of the superior hypogastric plexus does not alter the normal menstrual cycle. Fontaine and Herrmann noted that an atypical or supplementary menstrual period will occur on about the second postoperative day if the last regular menstrual period ended four or five days prior to the resection of the superior hypogastric plexus. They said: "We are inclined to believe that this is the result of an intense uterine congestion which follows the pelvic sympathectomy, and so it should not be considered as a true menstrual period. The subsequent menstrual period appears about twenty-eight days after the preoperative period and not in relation to the supplementary postoperative hemorrhagic discharge from the uterus." They further stated that there are many cases on record in which normal parturition took place when patients had previously been subjected to resection of the superior hypogastric plexus for the relief of some painful condition in the pelvis. Resection of the extrinsic genital nerves does not alter the normal menstrual cycle, does not interfere with spontaneous parturition and does not produce glandular atrophy, chronic pelvic congestion or any disturbances of motor function of the bladder or rectum. This should be clinical evidence that these genital nerves of the sympathetic nervous system are sensory rather than motor.

Fontaine and Herrmann and Leriche stated their belief that the hypogastric plexuses carry the important pathways of sensation from the internal genital organs to the medullary center, and that resection of the superior hypogastric plexus above the hypogastric ganglion is a safe, simple and effective way of interrupting these pathways in the treatment of functional dysmenorrhea, as well as a method of treating other forms of severe pelvic pain. We agree that presacral fibers undoubtedly carry afferent sensations of pain, but it is our opinion that the relief of pain in functional dysmenorrhea is obtained not only by cutting the pain fibers but from interruption of efferent fibers in the presacral group, which supply the blood vessels in the genitalia and the musculature of the uterus.

In order to relieve all pain arising in the region of the ovaries, it would be necessary to strip the ovarian artery by periarterial sympathectomy or by dividing the ovarian artery. Thus, by resecting the presacral nerve in conjunction with periarterial sympathectomy of both ovarian arteries or by sectioning the arteries, it should be possible to relieve pain both in the uterus and in the ovaries.

Cotte has demonstrated in more than 200 cases that pelvic pain was more completely relieved when resec-

¹³ Fontaine, Rene and Herrmann, L. G. Clinical and Experimental Basis for Surgery of the Pelvic Sympathetic Nerves in Gynecology. Surg. Gynec. & Obst. 54: 133-163 (Feb.) 1932.

tion of the presacral nerve was combined with other procedures, such as uterine suspension, freeing of adhesions and removal of chronically infected tubes. We can fully subscribe to the suggestions made by Cotte, Fontaine and Herrmann, and Leriche, that gynecologic lesions should be treated before sympathectomy is considered. We therefore divide dysmenorrheas into two groups: the true functional type without organic lesions, and those which are complicated by gynecologic lesions. As a rule, therefore, these patients are operated on by both gynecologic and neurologic surgeons. Before any type of sympathectomy has been performed the surgeon explores the pelvis and corrects the pathologic condition, and if not sufficient pathologic change is found to explain the pain, resection of the presacral nerve is performed as a single operation, or it is combined with resection of the lumbar trunk or with periarterial sympathectomy of the ovarian artery.

SURGICAL CONSIDERATIONS

We have not often resected the presacral nerve, but after observing the results obtained in the six cases presented here we are convinced that the operation is far more useful than we had previously considered. Our results correspond to similar results reported by foreign and American surgeons.¹ Since the operations were performed in these six cases, other operations have been performed by our colleagues in the clinic, these will be reported later.

Before adopting the presacral nerve procedure, we employed in one case the periarterial sympathectomy to the common iliac artery, and the internal and external iliac arteries on the left side, for intractable pain that had developed ten months after subtotal hysterectomy had been performed for fibromyomas. The pain was continuous and excruciating, and radiated from the left iliac fossa to the rectum. The patient was a woman, aged 38, the wife of a physician. At the time of operation, June 12, 1929, many adhesions were encountered and the left ovary was found to be sclerotic. The ovary was removed, adhesions were broken down, and the arteries were denuded of their adventitious coat for a distance of 5 cm. The peritoneum was subsequently closed to cover all denuded areas but, in spite of the rather extensive dissection, relief was not obtained. The failure to relieve pain in this particular case may have been due to the patient's unstable nervous system rather than to an ineffectual operation, since she complained of many other discomforts. However, the experience discouraged us in continuing periarterial sympathectomy of the iliac artery.

REPORT OF CASES

CASE 1—A woman, aged 27, admitted to the Mayo Clinic May 28, 1928, had been married nine years and was the mother of four children. Painful menstruation had been present for three years previous to which the periods had always been regular; they then varied from three to four weeks. The flow was moderate and continued for from seven to eight days. The pelvic pain was more or less constant and was much worse the day preceding the period with some cessation during the flow.

Physical and laboratory examinations revealed nothing abnormal except for slight lacerations of the cervix and slight mucoid discharge. The pain was not relieved by douches or treatment of the cervix, and June 9, 1928, a diagnostic dilation and curettage with cautery punctures of the cervix was performed. This decreased the cervical discharge but failed to relieve the pelvic pain which was more pronounced in the

left side of the pelvis than in the right. Aug. 19, 1931, the patient was readmitted to the hospital and laparotomy was performed, which included removal of the appendix for chronic catarrhal appendicitis, resection of the presacral nerve and division of the left lumbar sympathetic chain above the first sacral ganglion.

The patient's convalescence was uneventful; the wound healed by primary union, and she was dismissed from the hospital on the fourteenth postoperative day. Her last report, March 6, 1933, stated that she had been completely relieved of pain and considered the result 100 per cent successful. There had been no change in the menstrual cycle except that it had become more regular, but the flow had increased and now continued the full eight days and occasionally an extra day. There had been no further pregnancies.

CASE 2—A single woman, aged 22, was admitted to the clinic July 5, 1929, complaining of painful menstruation since its onset at the age of 12 years, the pain had become much more severe in the two years previous to admission. The periods were regular, occurring every twenty-eight days, with a moderate flow lasting from five to six days. The cramping pains began ten days before onset of the flow, occurred every two hours and lasted from ten to twelve minutes, causing the patient to double up during the paroxysm.

The physical and laboratory examinations and the bimanual examination of the pelvis were negative. Diagnostic dilation and curettage with insertion of a Baldwin tube was advised.

At operation, Aug. 15, 1931, the cervix was found to be soft and was easily dilated. The uterine scrapings revealed an atrophic endometrium. A Baldwin tube was inserted through the cervical canal and sutured in place to be left there for two regular menstrual periods. Unfortunately this procedure failed to give relief and the patient continued to have recurrent pains with catamenia, in spite of the fact that tincture of belladonna had also been administered. She returned for numerous subsequent examinations and on the date of her last registration, June 11, 1932, she was advised to have a laparotomy with a view of performing resection of the presacral nerve.

Laparotomy was carried out, June 15, 1932. The uterus was of normal size and position, with a small myoma in the anterior wall. The adnexa were normal. The gynecologic surgeon stated that there was not sufficient pathologic change in the pelvis to explain the pain and resection of the presacral nerves was performed by the neurologic surgeon. Convalescence was uneventful and the patient was dismissed from the clinic, July 6.

Subsequent reports from the patient have all been favorable. The last one, received Feb. 27, 1933, stated that she menstruated every twenty-four days. The flow was shorter than previously, lasting approximately three and a half days, and it had decreased. We asked the patient to express in percentage the relief experienced, and she stated that it has been 100 per cent, for the first time in her life she had been free from pain during catamenia and her only discomfort now is a little tenderness in the small of the back during the first day of menstruation.

CASE 3—A schoolgirl, aged 17 years, was registered at the clinic, June 16, 1932, because of dysmenorrhea, which came on with the onset of the menstrual periods at the age of 12 years. Many types of treatment, including morphine hypodermically, had been tried.

General and laboratory examinations were negative. The hymen being intact, the pelvis was examined bimanually through the rectum. The patient was advised to have a pelvic examination under ether with dilation and curettage, to be followed by resection of the presacral nerves if the diagnostic curettage was negative.

June 18 the uterus was curetted. Aside from a slightly hypertrophied endometrium nothing was found to explain the dysmenorrhea, and laparotomy was immediately performed. The uterus was retroflexed but was easily replaced. A small hydatid cyst of Morgagni was found in the right tube and this was removed preliminary to resection of the presacral nerve. The operative convalescence was uneventful and the patient was dismissed from the clinic July 7.

The patient reported after the first two or three menstrual periods following sympathectomy that she had been conscious

¹⁷ Wetherell, F. S. Relief of Pelvic Pain by Sympathetic Neurectomy. To be published.

of some discomfort during catamenia but that the pain was only 50 per cent as severe as before the operation. With subsequent menstrual periods, the pain had gradually subsided and by March 4, 1933, her relief, estimated in percentage, was 95. The menstrual periods now lasted five days, whereas previously they had lasted seven days but the flow had been much more profuse since the operation. The patient's constipation had not been relieved by resection of the presacral nerve. Immediately following operation, two menstrual periods had been missed.

CASE 4—A woman, aged 18, a teacher, came to the clinic July 6, 1932, because of dysmenorrhea and symptoms of Raynaud's disease in the lower extremities. Slight vasomotor changes had also occurred in the hands. Symptoms of Raynaud's disease began in the winter of 1931 and again recurred in the autumn. During the winter the menstrual flow was irregular, it occurred every six to eight weeks, was scanty, lasted five days and was associated with cramping pains. In the summer the menstrual cycle was regular and only slight discomfort was experienced.

The patient's symptoms of Raynaud's disease responded favorably to the preoperative vaccine which indicated that she would receive benefit from bilateral lumbar sympathetic ganglionectomy and trunk resection. July 13 this operation was performed in conjunction with resection of the presacral nerve. The abdominal exploration was negative except for a cystic ovary on the left which contained about 3 cc of yellow, gelatinous fluid. The cyst was removed and the remaining portion of the ovary was preserved. Convalescence was without incident and the patient was dismissed from the clinic August 1.

Following operation, symptoms of Raynaud's disease that is, asphyxia followed by cyanosis and rubor disappeared completely and have not returned. March 8, 1933, the patient reported that her menstrual periods had been regular during the winter of 1933, the flow had lasted five days and was more profuse than before. She was free from cramps during catamenia but she was conscious of a backache. She evaluated the result obtained from operation as 75 per cent successful.

CASE 5—A woman, aged 18, a laboratory technician registered at the clinic, Nov. 11, 1930, complaining of dysmenorrhea which dated back to appendectomy performed five years previously. She had been examined at the clinic on numerous occasions before and since that date, because of illnesses such as tonsillitis, painful feet, trichophytosis, myopia and astigmatism, all of which had been more or less incidental to the painful menstrual periods. The various medications usually employed in the medical treatment of dysmenorrhea were given. Oct. 4, 1932, she returned to the clinic demanding surgical intervention.

On bimanual examination the uterus was found to be normal in size and movable in the anterior position. Menstruation was irregular, occurring about every five weeks, the flow continuing for four or five days. Severe cramps occurring two days before onset were often so severe that she was compelled to go to bed. She was advised to have a pelvic examination under ether and dilation and curettage of the uterus, with the understanding that, if definite lesions were not found in the pelvis, a laparotomy was to be performed followed by resection of the presacral nerve.

At operation, October 6, the cervix was found to be easily dilated and the uterine scrapings proved to be fairly normal. Exploration did not disclose pathologic change, the appendix had been cleanly removed with no unusual amount of adhesions, and the pelvic and abdominal organs were normal. Resection of the presacral nerve was carried out and the wound closed. The postoperative course was uneventful and the patient was dismissed from the clinic November 18.

The first menstrual period after sympathectomy was overdue one week and lasted only half as long as previously, which was from four to five days. The discomfort on the morning of onset was rather severe but by noon most of the symptoms had disappeared and the patient was able to be up and at work, whereas previously she had been compelled to remain in bed for two days during the catamenia. With each successive

menstrual period the discomfort became less. March 1, 1933, she admitted that she was completely relieved of pain during her menstrual periods, which now continue from three to four days with the flow about the same as before. This patient was married about a year before her operation but has had no children. She stated that she was free from pain during intercourse, which previously had been painful.

CASE 6—A woman, aged 22, a nurse, registered at the clinic Aug. 12, 1922, complaining of dysmenorrhea. She stated that the pain was localized in the left iliac region and was more or less constant throughout the month but was aggravated during menstruation. She too had been examined at the clinic previously for numerous discomforts, and appendectomy had been performed Dec. 26, 1928. The pelvic examination at that time revealed nothing abnormal. After trying a great variety of medical measures she again registered at the clinic Feb. 29, 1933, with the same complaint of dysmenorrhea and further medical measures were employed.

July 31, 1933, the presacral nerves on the promontory of the sacrum were dissected free and segments 5 cm long were removed. Convalescence was uneventful and the patient was dismissed from the clinic August 16, having had a normal menstrual period two weeks after the operation without any evidence of the old pain.

SUMMARY

The group of cases reported is too small to permit general conclusions, but the results obtained are so satisfactory that it seems justifiable to employ the procedure for patients suffering from dysmenorrhea who cannot be relieved by medical measures such as endocrine therapy, the administration of tincture of belladonna, occasional doses of codine catharsis or hot douches at the onset of the menstrual periods.

THE TEACHING OF INDUSTRIAL HYGIENE

LEVERETT D. BRISTOL, MD, DRPH
Health Director, American Telephone and Telegraph Company
NEW YORK

The New York State Health Commission, which was organized by President Franklin D. Roosevelt when he was governor of New York, recommended among other things in its report¹ that "additional courses in industrial hygiene be established in medical and public health schools."

SPECIAL SURVEY AND COOPERATIVE STUDY

From past experience in medical and public health teaching and administration and from the standpoint of present work in the field of industrial health service, I have been interested in making a survey of the present practices and recent trends in the teaching of industrial hygiene in the medical and public health schools of the United States and Canada. The study is based on written and printed material in the form of letters and school bulletins received from deans and other faculty members of the various colleges and universities. To all these persons individually and collectively, I express my sincere appreciation of the cooperative services they have rendered in contributing to this study.

DEFINITIONS AND CLASSIFICATIONS

The word hygiene is a much abused term. It may be defined as "the science of health and of its preservation." Moreover, the various classifications and sub-

¹Read before the Annual Congress on Medical Education and Licensure, Chicago, Feb. 13, 1934.
²Public Health in New York State, New York State Department of Health, Albany, 1932.

divisions of the general subject of hygiene have followed no well ordered plan. Thus one speaks of prenatal hygiene, infant hygiene, preschool hygiene, child hygiene and adult hygiene, relating to time factors in the development of human life, maternal hygiene, sex hygiene and mental hygiene, having to do with physiologic functions, and mouth hygiene, dental hygiene and ocular hygiene dealing with special anatomic structures. One also has come to associate three of the common divisions of hygiene with particular organized community activities including home hygiene, school hygiene and industrial hygiene, all three of which may be grouped together under institutional hygiene, having many factors and features in common. The words industrial hygiene also have been used carelessly and improperly in much medical thinking and writing. With no thought for their real meaning, the words industrial hygiene, industrial medicine and industrial or occupational diseases in many instances have been used erroneously and more or less interchangeably as synonymous terms.

Industrial hygiene may be defined as the science of health and of its preservation among workers in industry. It should involve primarily a program of health conservation and disease prevention. Industrial medicine, surgery, nursing, sanitation and health education are a few of the means for carrying out a program. Specific industrial or occupational diseases, poisonings and accidents are some of the conditions to be combated in any adequate program of industrial hygiene, but, taken by and large, they are not the most important disability problems in industry. The common cold and other diseases of the respiratory system, including pulmonary tuberculosis, the usual diseases of the digestive, nervous and circulatory systems, and the so-called degenerative diseases of advancing years are the conditions of paramount importance as causes of disability and loss of time from work. Industrial hygiene is not a matter primarily of combating poisons and bandaging fingers but rather of preventing the common diseases of adult life and, through education and other means, of building up positive health and encouraging the development of proper health habits among employees. Moreover, the common sickness hazard is much greater than the accident hazard in industry. As indicated in the report of the New York State Health Commission,¹ "the greatest opportunities for an industrial health service lie in health promotion activities in which the emphasis is on preventing rather than cure."

In view of the numerous "hygienes" and other specialties claiming recognition and knocking at the door of the medical school curriculum there is little wonder that the average dean looks on their proponents as big bad wolves ready to destroy the major fundamentals of medical education by the substitution of many minor subjects. In this connection, it is not without some degree of sympathy and trepidation that I approach the subject of the teaching of industrial hygiene.

ELEMENTS OF AN ADEQUATE INDUSTRIAL HEALTH PROGRAM

Before proceeding further with a consideration of the subject of instruction in industrial hygiene, it may be well briefly to bring into focus what it is wished to teach, in other words. What are the fundamental elements of an adequate industrial health program? An answer to this question may point the way to the subject matter and methods that logically should be

included in a well rounded plan for collegiate education on this subject.

From the standpoint of present practice in the larger companies, the industrial health program usually is organized as a part of the general personnel program under a vice president or other business official who is director of personnel and public relations of the company. The director of health and safety, the medical director, or whatever may be the title of the person directly in charge of health activities, reports as a rule to the personnel director or one of his assistants.

An outline of the sections, subdivisions and relative values of a personnel and industrial relations program, of which the health program usually is a part, was suggested by me² in 1932. A further detailed presentation of proposed industrial health programs for large and small companies was published in 1933.³ The scope of the present study does not permit of a repetition of these outlines. For a detailed description of an industrial health program and a new appraisal form or yardstick for the measurement of an industrial health service, as well as a brief account of the functions of and parts played by medical, nursing and allied services, reference is made to a recently published book⁴ on this subject.

The general subjects included in an industrial health program which should be covered in the teaching of industrial hygiene may be outlined briefly as follows:

- 1 Vital statistics activities including death, sickness and accident records, reports and studies of company employees.

- 2 Communicable disease control, including case investigations and records, medical and nursing service and specific immunization. Special attention to the prevention and control of tuberculosis among employees.

- 3 Occupational disease and accident control, including records, case investigations and reports, medical examinations and assurance of adequate treatment, observance of laws and regulations and education of employees on and protection against specific hazards.

- 4 Personal and environmental hygiene of office, shop, store, factory and outdoor field workers, including daily observation, periodic inspection, medical examinations (including pre-employment and periodic), assurance of adequate medical treatment, field or nursing visits, building and factory sanitation, lighting, heating and ventilation, food and milk control in cafeterias, health and safety education and publicity, and recreation and rest facilities.

- 5 Related subjects, including a consideration of the functions of an industrial physician and his relation to the management and working forces, the organization of company medical and nursing units and a brief review of the other features of a complete industrial personnel program, including various employment, educational, economic and cooperative activities, not the least of which have to do with provisions, such as benefits, compensation or insurance, against the risks of death, sickness, accidents and unemployment.

BEGINNINGS OF INSTRUCTION IN INDUSTRIAL HYGIENE

Just as public health and preventive medicine in general began largely with attention to environmental hygiene or sanitation and later developed into the "newer public health," which promoted personal hygiene to equal rank in importance with sanitation, so also industrial health has evolved from a primary interest in environmental hazards causing sickness and accidents in a few industries to an equal interest in the

personal hygiene and health habits of the individual workers of all industries. The same evolution has been evident not only in the practice of industrial hygiene but also in education on this subject through books and organized courses and classes.

Publications—The first knowledge of and instruction in industrial hygiene came through books and other publications on specific occupational diseases.

TABLE 1—*Medical Schools That Give Separate Courses in Industrial Hygiene*

Schools	Courses
Chicago	Elective course in industrial medicine only under department of internal medicine
Cincinnati	Special short course for senior medical and graduate students
Colorado	Elective course for medical and graduate students under department of bacteriology and public health
Columbia	Separate courses in industrial medicine and industrial physiology under institute of public health, for candidates for public health degree
Harvard (School of Public Health)	Separate courses in industrial medicine and in industrial hygiene and sanitary engineering
Illinois	Separate course for seniors, lectures and demonstrations in cooperation with state department of public health
Johns Hopkins (School of Public Health)	Subject matter of industrial hygiene treated in several separate courses under department of physiologic hygiene
Long Island	Separate course of lectures in industrial hygiene for third year medical students under department of preventive medicine and community health
McGill (Canada)	Separate courses of lectures and demonstrations to third year medical students and graduate students
Michigan	Elective course in industrial hygiene open to medical students and candidates for public health degree
Pennsylvania	Separate course for graduate students and candidates for public health degree
Toronto, Canada (School of Hygiene)	Separate lecture and demonstration course for candidates for public health degree
Yale	Elective course for medical and public health students

Hippocrates, Galen, Pliny and others referred in their writings to certain occupations that resulted in sickness more or less as cause and effect. It was not until about 1700 that Ramazzini,⁵ an Italian, published the first book on diseases associated with special occupations. Following this work, various articles on occupational diseases appeared in medical and health literature, and other books and monographs were published by Thackrah, des Planches, Haffort, Meier, Delpech, Kussmaul, Eulenberg, Hirt and Layet from 1800 to 1875. Since then, numerous modern works on industrial hygiene have been published by English, French, German and American authors.

College Lectures and Courses—The organized teaching of industrial hygiene in the schools and colleges of this country started in the form of a few special lectures on this subject included in the regular courses on preventive medicine and public health. Kober at Georgetown Medical School in Washington, D. C., was one of the first who gave such lectures, as early as 1890. Beginning about 1905, Winslow gave instruction in industrial hygiene as a special course at the Massachusetts Institute of Technology, where such instruction has been continued by other teachers. Since then, various medical and public health schools throughout the United States and Canada have organized lectures, separate courses and special research in industrial hygiene.

PRESENT PRACTICES IN THE TEACHING OF INDUSTRIAL HYGIENE

Based on letters, personal communications and published bulletins received from deans and other faculty members, an attempt has been made to outline briefly in the accompanying tables the present practice in the teaching of industrial hygiene in the medical and public health schools of the United States and Canada. This study does not include a few nonmedical colleges or schools that may give such instruction.

Separate Courses—Out of eighty-five medical and public health schools from which information was sought, sixty-six supplied data for this study. Of these sixty-six, there are only thirteen schools that give separate courses in industrial hygiene, as outlined in table 1.

Separate Lectures—Of the sixty-six supplying information, twenty-four medical schools assign one or more separate lectures to industrial hygiene in their general public health or hygiene courses. These schools with the number of lectures are given in table 2.

General Instruction—Another group of medical schools, while not reporting the assignment of any definite time to industrial hygiene, gives brief attention to the subject in the general public health or hygiene courses. Eighteen such schools out of the sixty-six are listed in table 3.

Table 4 indicates the names of another group of twenty-one medical schools which, from information available, give no specific instruction in industrial

hygiene. However, in some of these institutions, instruction on closely related subjects is covered briefly in other courses.

Field Instruction and Surveys—It may be stated that field visits to industrial plants for inspection and surveys should be to the teaching of industrial hygiene, what hospital ward rounds are to the teaching of clinical medicine. The fifteen schools (twelve medical and three public health) listed in table 5 report that they make available such field trips to industrial plants as a

part of their instruction in industrial hygiene. Other schools require at least occasional field investigations of industrial hazards, or brief inspections.

Clinics and Theses—In addition to regularly organized instruction and field trips, a few schools require written theses on subjects in industrial hygiene, and two or three, in cooperation with associated hospitals, have organized special clinics for industrial diseases. The use of additional outside specialists in industrial hygiene, as guest speakers, is a feature of the instruction in a few schools.

No information relative to the teaching of industrial hygiene was received from the following medical schools: Arkansas, Buffalo, Dalhousie (Canada), Detroit, Emory, Hahnemann, Laval (Canada), Louisiana, Manitoba (Canada), Maryland, Minnesota, Montreal (Canada), North Dakota, St. Louis, South Dakota, Temple, Tennessee, Vermont and Wake Forest. Some of these schools are located in more or less agricultural states or provinces with little interest in industrial hygiene, while a few are two year schools which include only fundamental preclinical subjects and courses. With one or two possible exceptions, it may safely be said that little or no instruction in industrial hygiene is given in these schools.

FUTURE OBJECTIVES AND DEVELOPMENT OF INSTRUCTION IN INDUSTRIAL HYGIENE

One of the objectives in training medical students for work in industrial hygiene which well might be a guide in the future, has been expressed as follows by one of the teachers in this subject:

Our work in industrial hygiene is so planned that our students may have some knowledge of the problem as one of prevention. It seems to me that for many years the work will be done for the most part by general men and that it is very important to send our men out with the prevention idea well hammered in.

Another teacher of industrial hygiene says:

Our conception of industrial hygiene is that it bears the same relationship to adult health that school hygiene bears to child health and we think that in many respects the teaching

of toxicology is less important than other things. We base our opinion on the fact that comparatively few industrial workers suffer from industrial poisoning, whereas a great number suffer from tuberculosis, cardiovascular disease and, not least of all, upper respiratory infections. With this viewpoint, we try to shape our lectures along the lines of adult hygiene.

One dean writes:

Personally I regard the subject of industrial hygiene as extremely important. I wish very much that more time could be devoted to it in the medical curriculum. The subject is one of growing importance. Not only the lay public but the profession in general is in need of education in this field.

Another states as follows:

With the coming of the depression our students who were preparing for work as plant physicians, and taking a number of courses, practically disappeared, but with the present social trend in medicine there is no doubt such men will reappear and it is our conviction that the general student in public health now should have more work in what may be called industrial hygiene.

Groups to be Reached and Available Instruction—There are three groups of medical students to be reached with instruction in industrial hygiene:

1 Those who expect to become private practitioners of medicine and surgery but who eventually may give part time to industrial health work.

2 Those who expect to take up general public health work on a full time basis in a state, city or county department of health.

3 Those who anticipate devoting full time to industrial health service as a specialty.

For the first group it would seem desirable to furnish instruction in medical schools preferably during the latter part of the course. This should be in the form of a separate course in industrial hygiene, or as a series of at least three or four lectures on industrial hygiene included in the general course on public health, preventive medicine or hygiene.

For those who may be included in the second and third groups of students mentioned, separate courses should be available, as graduate courses in departments or schools of public health, with more advanced courses

TABLE 5—*Medical Schools Which Report That They Make Available Field Trips to Industrial Plants as a Part of Their Instruction in Industrial Hygiene*

and research for those anticipating industrial hygiene as a specialty.

It also would seem desirable to make courses available for at least three groups of nonmedical students:

1 Those who seek degrees or certificates in public health for full time nonmedical health work.

2 Those seeking public health nursing degrees, particularly those expecting to go into industrial work.

3 Those who, as students or as lay business executives, wish to obtain training in a school or college of business administration including courses on industrial personnel administration and health.

For the first group of such nonmedical students, separate courses in industrial hygiene should be available in schools of public health. Such courses also should be available for prospective industrial nurses either in nursing schools or as open courses offered by members of the medical or public health faculty.

For business executives and beginning students of business administration, courses in industrial hygiene, suited to their preliminary training and needs, should be included in the curriculums of university schools of business administration. In larger universities having under their jurisdiction several different schools, such as medical, public health, business administration and nursing, the professor of industrial hygiene might well serve all the schools in teaching, correlation of staff activities and direction of research investigations.

Department Organization and Administration—One present weakness in the teaching of industrial hygiene in graduate schools of public health is that it may be masked or more or less hidden under some other group or departmental designation. The growing importance of industrial hygiene would seem to warrant, as soon as economically feasible, the placing of this branch of instruction "on its own feet" and under its own independent development—at least in schools of public health, through a separate department of industrial hygiene under a full time professor. In place of two or three administratively unrelated departments in schools of public health, it would seem to be in the interest of logical organization, coordination and administration to set up one department of industrial hygiene and to have the professor of industrial hygiene serve as a coordinator and interpreter of the different phases of the subject, including industrial medicine, which may be represented by subdivisions of the one department. Preferably such a teacher and department director should be a physician with previous experience in industrial health administration.

When feasible, such departments of industrial hygiene in schools of public health should maintain close working relations with the industries of the community to the end that some of the members of the medical and health staffs of local industrial organizations may be represented in the school teaching staff. A "practical" teacher of industrial hygiene who has industrial connections should be as valuable and necessary as a clinical teacher of medicine who has hospital connections. Medical and public health schools that give instruction on this subject also should cultivate the friendly cooperation of local industries in order to enhance their facilities for field training of students in industrial hygiene.

Proposed Museums of Hygiene—If I were to be suddenly transformed into a professor of industrial hygiene, or a dean of a medical or public health school, one of the first things I would be tempted to do would be to suggest the possible organization of a departmental museum of industrial hygiene or a school museum of general hygiene, in which a section on industrial hygiene could have a prominent place. Much emphasis has been put in medical education on museums of the dead, associated with departments and institutes of anatomy and pathology, why not, in connection with the departments and institutes or schools of hygiene, create museums that would have to do with the living and with keeping the living safe and well? With the cooperation of ethical commercial firms, permanent

museums containing exhibits having to do with the maintenance of health and safety and the prevention of sickness and accidents might be easily and inexpensively organized to the advantage of coming generations of medical and public health students. If brief and temporary health and safety exhibits are valuable and desirable in connection with medical association meetings, health association meetings and world exhibitions of progress, why may not museums on a small, carefully selected and permanent scale also be worth while as visual adjuncts to fundamental training in hygiene and preventive medicine? Moreover, if open to the public, such museums of hygiene would serve as permanent, community educational assets. If necessary, the interest and assistance of philanthropic foundations and funds might be enlisted to provide suitable space or buildings for such collegiate museums of hygiene.

Details of Instruction—In the foregoing statements with reference to the future objectives and the further development of instruction in industrial hygiene, an attempt has been made only to set forth a few general principles and to indicate some of the important phases of organization and administration. While some reference is made to the number and extent of lectures and courses in industrial hygiene, the exact details and character of such instruction necessarily must be worked out by various schools and departments on the basis of available facilities, local conditions and needs.

SUMMARY AND CONCLUSIONS

1 Of eighty-five medical and public health schools in the United States and Canada covered in this study, information has been received from sixty-six with reference to the teaching of industrial hygiene, of the sixty-six, only thirteen schools (ten medical and three public health) give separate courses in industrial hygiene, twenty-four medical schools assign one or more separate lectures to industrial hygiene in their general public health or hygiene courses, eighteen schools give only brief attention to industrial hygiene, and another twenty-one together with a number of schools unheard from, apparently give no instruction in this subject.

2 From this study, it is evident that a wide range of practice in the teaching of industrial hygiene exists at present among the various medical and public health schools throughout the United States and Canada. It is natural and reasonable to suppose that those schools and colleges associated with universities in the more populous urban and industrial states and provinces will have more demand on the part of students and more adequate facilities for instruction in industrial hygiene than will those located in rural and agricultural parts of the country. The further development of teaching and research on this subject in various institutions naturally must depend largely on such local conditions and requirements.

3 Field visits to industrial plants for inspections and surveys should be to the teaching of industrial hygiene what hospital ward rounds are to the teaching of clinical medicine, fifteen schools (twelve medical and three public health) report that they make such field trips available. Medical and public health schools that give instruction in this subject should cultivate the friendly cooperation of local industries in order to enhance their facilities for field training of students in industrial hygiene.

4 For those students who expect to become private practitioners of medicine and surgery but who eventually may give part time to industrial health work, it would seem desirable to furnish instruction in medical schools, preferably during the latter part of the course. This should be in the form of a separate course in industrial hygiene or a series of at least three or four lectures on industrial hygiene included in the general course on public health, preventive medicine or hygiene.

5 For those medical or nonmedical students who expect to take up general public health work on a full time basis or to specialize in industrial health service, separate courses should be available as graduate and advanced courses in departments or schools of public health.

6 For those students or lay business executives who wish to specialize or take graduate courses in business or personnel administration, courses in industrial hygiene adapted to the use of such students should be included in the curriculums of university schools of business administration.

7 Instruction in industrial hygiene, including industrial medicine, industrial sanitation, industrial toxicology and other subjects, at least in graduate schools of public health and when economically feasible, should be organized under one separate, independent department of industrial hygiene with a full time professor as coordinator and director. He should be a physician with experience in industrial health administration and in the larger universities he might also serve as the director or teacher of courses on this subject in medical, nursing, business or other schools.

8 Much emphasis in medical education has been put on museums of the dead, associated with departments and institutes of anatomy and pathology. It is suggested that, in connection with the departments, institutes or schools of hygiene, museums or exhibits be created which would have to do with the living, and with keeping the living safe and well. In such proposed museums, exhibits pertaining to industrial hygiene and safety should be assigned prominent locations.

9 Detailed subject matter and methods of teaching industrial hygiene must be based on local conditions, facilities and needs as well as on knowledge of the elements of an adequate industrial health program, a brief outline for which, based on an appraisal form for industrial health service, as recently developed by me, has been presented.

10 Industrial hygiene may be defined as the science of health and of its preservation among workers in industry. It should involve primarily a program of health conservation and of disease and accident prevention. It is not alone a matter of combating poisons and bandaging fingers but rather of preventing the common diseases and mishaps of adult life and through medical and nursing service sanitation education and other means of building up positive health and encouraging the development of proper health habits among working people in general.

11 Industrial hygiene including industrial medicine will become what physicians and medical educators help the business man and industrial worker to make it. In this connection opportunities and responsibilities are unlimited for the development of the right sort of leadership among future generations of medical students.

THE LAXATIVE EFFECT OF A REGENERATED CELLULOSE IN THE DIET

ITS INFLUENCE ON MINERAL RETENTION

HARRIET MORGAN, PH D
CHICAGO

A balance experiment was conducted on eight subjects for the purpose of determining the laxative efficacy of a regenerated cellulose and its influence on mineral balance. An adequate diet was given for a nine day control period, with preliminary and collection periods. Then the same diet plus 20 Gm a day of (nitrogen-free, phosphorus-free and calcium-free) cellulose was given for a nine day test period with preliminary and collection periods. This paper briefly describes my experimental procedure and states my observations regarding the ingestion of a regenerated cellulose.

LAXATIVE EFFECT

Numerous writers on the subjects of constipation recognize the importance of food residues in promoting elimination. Great differences of opinion exist, however as to the best source and physical form of the roughage material to be used. Vegetables, fruits, bran and more recently, a purified cellulose in the form of prepared cereals have all been used to contribute an indigestible residuum to the diet. Few studies, however, can be found on the laxative effect of regenerated cellulose. Frey and his associates¹ in 1928 reported experiments with edible pure cellulose. Laxation was increased from an average of 0.88 bowel movement a day to 1.63 movements a day in orphanage children to whose diet 7 per cent of this cellulose was added. There were no harmful results. With rats, death resulted from adding to the diet 2.5 per cent of coarse rice cellulose or 25 per cent of an all bran prepared cereal. These workers did not state their method of preparing pure cellulose, and descriptions of the methods they probably used² are too general to give specific knowledge of preparation of the purified cellulose.

The nutrition laboratory at Cornell University obtained a cellulose, found to be calcium free, nitrogen free, and phosphorus free and containing 90 per cent crude fiber. The cellulose³ was ground through a mesh sieve, with holes 0.073 inch in diameter, and then sifted through a 10 mesh flour sieve. The ground and sifted product resembled coarse white corn meal. This cellulose had been fed with no detrimental effects to various species of animals throughout their life spans. In order to test the laxative potency and harmlessness of the material, I daily ingested 5, 10 and 20 Gm amounts in a series of three five-day experiments. The 5 and 10 Gm amounts had no laxative effect. Twenty grams of the cellulose was appreciably laxative. To determine whether the cellulose could be used advantageously and safely to supplement a low roughage diet of the type that tends to induce constipation, a human experiment was planned.

The data in this paper are taken from a thesis submitted by the author to the Graduate School Cornell University in partial fulfillment of the requirements for the degree of Doctor of Philosophy.

Acknowledgments are made to Dr C M McCay under whose direction the work was conducted to the students who cooperated in the experiment and to R LaT Cavanaugh Cornell University Medical College for advice and assistance in preparing the manuscript.

² Hamor W A. U S patent number 1,495,789.

³ This regenerated cellulose was furnished through the courtesy of the Sylvania Industrial Corporation. Before being ground it presented the appearance of the well known cellophane.

For the first group of such nonmedical students, separate courses in industrial hygiene should be available in schools of public health. Such courses also should be available for prospective industrial nurses either in nursing schools or as open courses offered by members of the medical or public health faculty.

For business executives and beginning students of business administration, courses in industrial hygiene, suited to their preliminary training and needs, should be included in the curriculums of university schools of business administration. In larger universities having under their jurisdiction several different schools, such as medical, public health, business administration and nursing, the professor of industrial hygiene might well serve all the schools in teaching, correlation of staff activities and direction of research investigations.

Department Organization and Administration—One present weakness in the teaching of industrial hygiene in graduate schools of public health is that it may be masked or more or less hidden under some other group or departmental designation. The growing importance of industrial hygiene would seem to warrant, as soon as economically feasible, the placing of this branch of instruction "on its own feet" and under its own independent development—at least in schools of public health, through a separate department of industrial hygiene under a full time professor. In place of two or three administratively unrelated departments in schools of public health, it would seem to be in the interest of logical organization, coordination and administration to set up one department of industrial hygiene and to have the professor of industrial hygiene serve as a coordinator and interpreter of the different phases of the subject, including industrial medicine, which may be represented by subdivisions of the one department. Preferably such a teacher and department director should be a physician with previous experience in industrial health administration.

When feasible, such departments of industrial hygiene in schools of public health should maintain close working relations with the industries of the community to the end that some of the members of the medical and health staffs of local industrial organizations may be represented in the school teaching staff. A "practical" teacher of industrial hygiene who has industrial connections should be as valuable and necessary as a clinical teacher of medicine who has hospital connections. Medical and public health schools that give instruction on this subject also should cultivate the friendly cooperation of local industries in order to enhance their facilities for field training of students in industrial hygiene.

Proposed Museums of Hygiene—If I were to be suddenly transformed into a professor of industrial hygiene, or a dean of a medical or public health school, one of the first things I would be tempted to do would be to suggest the possible organization of a departmental museum of industrial hygiene or a school museum of general hygiene, in which a section on industrial hygiene could have a prominent place. Much emphasis has been put in medical education on museums of the dead, associated with departments and institutes of anatomy and pathology, why not, in connection with the departments and institutes or schools of hygiene, create museums that would have to do with the living and with keeping the living safe and well? With the cooperation of ethical commercial firms, permanent

museums containing exhibits having to do with the maintenance of health and safety and the prevention of sickness and accidents might be easily and inexpensively organized to the advantage of coming generations of medical and public health students. If brief and temporary health and safety exhibits are valuable and desirable in connection with medical association meetings, health association meetings and world exhibitions of progress, why may not museums on a small, carefully selected and permanent scale also be worth while as visual adjuncts to fundamental training in hygiene and preventive medicine? Moreover, if open to the public, such museums of hygiene would serve as permanent, community educational assets. If necessary, the interest and assistance of philanthropic foundations and funds might be enlisted to provide suitable space or buildings for such collegiate museums of hygiene.

Details of Instruction—In the foregoing statements with reference to the future objectives and the further development of instruction in industrial hygiene, an attempt has been made only to set forth a few general principles and to indicate some of the important phases of organization and administration. While some reference is made to the number and extent of lectures and courses in industrial hygiene, the exact details and character of such instruction necessarily must be worked out by various schools and departments on the basis of available facilities, local conditions and needs.

SUMMARY AND CONCLUSIONS

1 Of eighty-five medical and public health schools in the United States and Canada covered in this study, information has been received from sixty-six with reference to the teaching of industrial hygiene, of the sixty-six, only thirteen schools (ten medical and three public health) give separate courses in industrial hygiene, twenty-four medical schools assign one or more separate lectures to industrial hygiene in their general public health or hygiene courses, eighteen schools give only brief attention to industrial hygiene, and another twenty-one together with a number of schools unheard from, apparently give no instruction in this subject.

2 From this study, it is evident that a wide range of practice in the teaching of industrial hygiene exists at present among the various medical and public health schools throughout the United States and Canada. It is natural and reasonable to suppose that those schools and colleges associated with universities in the more populous urban and industrial states and provinces will have more demand on the part of students and more adequate facilities for instruction in industrial hygiene than will those located in rural and agricultural parts of the country, the further development of teaching and research on this subject in various institutions naturally must depend largely on such local conditions and requirements.

3 Field visits to industrial plants for inspections and surveys should be to the teaching of industrial hygiene what hospital ward rounds are to the teaching of clinical medicine, fifteen schools (twelve medical and three public health) report that they make such field trips available. Medical and public health schools that give instruction in this subject should cultivate the friendly cooperation of local industries in order to enhance their facilities for field training of students in industrial hygiene.

4 For those students who expect to become private practitioners of medicine and surgery but who eventually may give part time to industrial health work, it would seem desirable to furnish instruction in medical schools, preferably during the latter part of the course. This should be in the form of a separate course in industrial hygiene or a series of at least three or four lectures on industrial hygiene included in the general course on public health, preventive medicine or hygiene.

5 For those medical or nonmedical students who expect to take up general public health work on a full time basis or to specialize in industrial health service, separate courses should be available as graduate and advanced courses in departments or schools of public health.

6 For those students or lay business executives who wish to specialize or take graduate courses in business or personnel administration, courses in industrial hygiene adapted to the use of such students should be included in the curriculums of university schools of business administration.

7 Instruction in industrial hygiene, including industrial medicine, industrial sanitation, industrial toxicology and other subjects, at least in graduate schools of public health and when economically feasible, should be organized under one separate, independent department of industrial hygiene with a full time professor as coordinator and director. He should be a physician with experience in industrial health administration and in the larger universities he might also serve as the director or teacher of courses on this subject in medical, nursing, business or other schools.

8 Much emphasis in medical education has been put on museums of the dead, associated with departments and institutes of anatomy and pathology. It is suggested that, in connection with the departments, institutes or schools of hygiene, museums or exhibits be created which would have to do with the living, and with keeping the living safe and well. In such proposed museums, exhibits pertaining to industrial hygiene and safety should be assigned prominent locations.

9 Detailed subject matter and methods of teaching industrial hygiene must be based on local conditions, facilities and needs as well as on knowledge of the elements of an adequate industrial health program, a brief outline for which, based on an appraisal form for industrial health service, as recently developed by me, has been presented.

10 Industrial hygiene may be defined as the science of health and of its preservation among workers in industry. It should involve primarily a program of health conservation and of disease and accident prevention. It is not alone a matter of combating poisons and bandaging fingers but rather of preventing the common diseases and mishaps of adult life and, through medical and nursing service, sanitation education and other means of building up positive health and encouraging the development of proper health habits among working people in general.

11 Industrial hygiene including industrial medicine, will become what physicians and medical educators help the business man and industrial worker to make it. In this connection opportunities and responsibilities are unlimited for the development of the right sort of leadership among future generations of medical students.

THE LAXATIVE EFFECT OF A REGENERATED CELLULOSE IN THE DIET

ITS INFLUENCE ON MINERAL RETENTION

HARRIET MORGAN, PH D
CHICAGO

A balance experiment was conducted on eight subjects for the purpose of determining the laxative efficacy of a regenerated cellulose and its influence on mineral balance. An adequate diet was given for a nine day control period, with preliminary and collection periods. Then the same diet plus 20 Gm a day of (nitrogen-free, phosphorus-free and calcium-free) cellulose was given for a nine day test period, with preliminary and collection periods. This paper briefly describes my experimental procedure and states my observations regarding the ingestion of a regenerated cellulose.

LAXATIVE EFFECT

Numerous writers on the subjects of constipation recognize the importance of food residues in promoting elimination. Great differences of opinion exist, however as to the best source and physical form of the roughage material to be used. Vegetables, fruits, bran and more recently, a purified cellulose in the form of prepared cereals have all been used to contribute an indigestible residuum to the diet. Few studies, however, can be found on the laxative effect of regenerated cellulose. Frey and his associates¹ in 1928 reported experiments with edible pure cellulose. Laxation was increased from an average of 0.88 bowel movement a day to 1.63 movements a day in orphanage children to whose diet 7 per cent of this cellulose was added. There were no harmful results. With rats, death resulted from adding to the diet 2.5 per cent of coarse rice cellulose or 25 per cent of an all bran prepared cereal. These workers did not state their method of preparing pure cellulose, and descriptions of the methods they probably used² are too general to give specific knowledge of preparation of the purified cellulose.

The nutrition laboratory at Cornell University obtained a cellulose, found to be calcium free, nitrogen free, and phosphorus free and containing 90 per cent crude fiber. The cellulose³ was ground through a mesh sieve, with holes 0.073 inch in diameter, and then sifted through a 10 mesh flour sieve. The ground and sifted product resembled coarse white corn meal. This cellulose had been fed with no detrimental effects to various species of animals throughout their life spans. In order to test the laxative potency and harmlessness of the material, I daily ingested 5, 10 and 20 Gm amounts in a series of three five-day experiments. The 5 and 10 Gm amounts had no laxative effect. Twenty grams of the cellulose was appreciably laxative. To determine whether the cellulose could be used advantageously and safely to supplement a low roughage diet of the type that tends to induce constipation, a human experiment was planned.

The data in this paper are taken from a thesis submitted by the author to the Graduate School, Cornell University, in partial fulfillment of the requirements for the degree of Doctor of Philosophy.

Acknowledgments are made to Dr. C. M. McCay under whose direction the work was conducted to the students who cooperated in the experiment and to R. LaT. Cavanaugh, Cornell University Medical College for advice and assistance in preparing the manuscript.

³ This regenerated cellulose was furnished through the courtesy of the Sylvania Industrial Corporation. Before being ground it presented the appearance of the well known cellophane.

EXPERIMENT

Seven students and one technician between the ages of 22 and 35, who were known to be reliable and honest were chosen for the experiment. Care was taken to select women subjects who would not experience menstruation during the experiment, in order to eliminate error in the balance study. None of the subjects reported a history of chronic constipation. All continued their regular work and activity during the experiment.

A low roughage type of diet which tends to produce constipation was planned. The amount of food served each subject was previously calculated according to the subject's weight, sex and activity. The subjects were however allowed to choose to eat as much as they desired during a preliminary period, but the amount chosen remained constant thereafter until the end of the experiment. The end of this preliminary period was marked by the ingestion of a carmine capsule and its appearance in the stools and collections were continued for the five day test period, another carmine capsule marked the end of this period. The subjects were allowed to drink water at will but were required to measure and record the amount. Representative samples of the food items were collected, according to standard methods⁴ and stored for later analysis.

Urine and feces were collected and the number of bowel movements was recorded for two five-day periods. During the first (control) period the diet was fixed as described, during the second period 20 Gm of the regenerated cellulose described was added daily to the basal diet. The cellulose was eaten with the breakfast cereal with sugar and milk.

RESULTS

The criteria of laxative value were (1) the dry weight of feces evacuated, (2) the water content of the stools, (3) the daily number of defecations and the subject's impression of the ease and completeness of evacuation.

1 Dry Weight of Feces—During the cellulose period the increase in dry weight of feces evacuated by the eight subjects varied from 56 to 193 per cent. In no case was there a reduction. The composite average of the series of subjects show a 69 per cent increase in dry weight of total feces excreted during the nine day period.

2 Water Content of the Stools—In all except one of the subjects the total water excreted in the feces during the cellulose period was markedly increased. Because of the increase also in dry weight excreted however, the moisture percentage of the stools shows very little change between the control period and the test period. The composite average of the series shows a 1.29 per cent increase in water content. Since individuals varied between a 12 per cent reduction and a 15 per cent increase in the water content during the test period, this criterion is considered of less value than the other criteria. Incidentally, there was a considerably lessened water intake during the cellulose period, the total for eight subjects averaging 1,616 cc for the control period and 1,121 cc for the test period, or about 100 cc less a day.

3 Completeness of Evacuation—The number of defecations during a day is commonly accepted as

indicative of the degree of laxation or constipation. In the case of human beings, however, the mere record of the number of bowel movements may prove inadequate. Because of the effect of habit or "conditioning" on the defecation reflex as the result of the highly organized social life, a wide individual variation in the number of daily movements occurs, which is yet within limits of perfect health.

Recent investigations prove that the addition of fibrous material to the diet increases the number of defecations. For example, Frey and his associates⁵ report that the average daily number of evacuations for the children of the group eating cellulose once daily was increased from 0.91 before the test to 1.54 during the test. Cowgill and Anderson⁶ report that the number of defecations varied from 0.7 to 2.4 a day (when the basal diet had been markedly constipating in its effect). Rose and her associates⁷ report that the addition daily of 14 Gm of prepared bran to the breakfast cereal of an adequate diet of thirty-eight girls from 10 to 16 years of age resulted in definitely increased laxation in 50 per cent of the cases.

In this study there were twelve no-movement days reported in the basal diet period and only four no-movement days in the cellulose period. The average number of defecations for the group for the five day basal diet period was 5.75 and for the cellulose period 8.25 an increase of 2.5 bowel movements in five days. This is a reasonable and definite increase in laxation. The evacuations were said to be complete and no subject reported irritation of the rectum during the control or test period.

Throughout the experiment the subjects felt better than they felt normally. There was no variation in weight greater than 0.55 Kg in any subject between the beginning and end of the experimental period. Moreover, all subjects were pleasant and in good humor even though practically the same diet was eaten for eighteen days.

METABOLIC EQUILIBRIUM

To study the effects of cellulose ingestion on nitrogen and mineral retention, the metabolic equilibrium of nitrogen, calcium, phosphorus and the free ash in the feces were determined.

Nitrogen—All subjects were in positive nitrogen balance throughout both the control and the cellulose periods of the experiment. Significant variations in the nitrogen balances occurred however. 1 All three female subjects were in greater positive nitrogen balance during the cellulose period than without cellulose. 2 All five male subjects had a smaller positive nitrogen balance with cellulose. 3 The males showed this relative loss of nitrogen because the nitrogen excreted in the feces was increased (average increase 41 per cent) during the cellulose ingestion. (The balance remained positive because of reduced nitrogen excretion in the urine.) An average of the entire group shows that during the cellulose period the nitrogen of the feces was 4.3 per cent greater than during the control period. Although nitrogen balance remained positive, this indicates a definite trend toward increased fecal nitrogen excretion as the result of the ingestion of cellulose.

⁷ Total nitrogen in all samples was determined by the Kjeldahl method.

⁴ Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists ed. 3 Association of Official Agricultural Chemists Washington D. C. 1930. Leach A. E. Food Inspection and Analysis ed. 4 New York J. Wiley & Sons 1920.

Phosphorus—All eight subjects were in positive phosphorus balance during the control period. During the cellulose period, however, three of the subjects were in negative balance and one was in exact equilibrium. An analysis as to whether this was a disturbance of fecal or of urinary phosphorus shows that the group as a whole excreted 66 per cent more phosphorus in the feces during the test period than during the control period, the intake remaining the same. The urinary phosphorus increased 30.1 per cent during the cellulose ingestion. From these figures I can only say that for some cause which I will not attempt to explain phosphorus excretion was increased during the cellulose period in view of only a 66 per cent increase in fecal phosphorus. I can make no positive additional statement as regards the effect of cellulose on fecal phosphorus alone.

Calcium—Six of the eight subjects were in positive calcium balance during the control period and five of the eight were in negative calcium balance during the cellulose period. The composite calcium deficit of the entire group during the cellulose period was 12.9 per cent. Of this 12.5 per cent was a fecal calcium loss and 0.4 was urinary. This definite reversal of the calcium equilibrium might be attributed to many causes but in my experiment the only difference between the control and test periods was the daily ingestion of 20 Gm of cellulose. I infer therefore with only very few reservations that the cellulose caused an increased calcium elimination in the feces.

Ash¹⁰—Fecal ash consists of measurable amounts of calcium, phosphorus, iron, sulphur, chlorine, sodium, potassium and magnesium and smaller amounts of silicon. The total ash for this entire series of subjects was 215.9 Gm during the control period and 271.8 Gm during the cellulose period. This is an increase of 25.9 per cent as the result of cellulose. I have already considered the calcium and phosphorus components of this increase. I have shown that the amount of calcium in the feces increases during the cellulose-containing diet period by 12.9 per cent and the amount of phosphorus by 66 per cent. The other minerals contributing to "total ash" therefore show a composite increased excretion of 6.4 per cent during the cellulose period. Thus in addition to definite losses of nitrogen, calcium and phosphorus there is a sizable loss made up of iron, sulphur, chlorine, sodium, potassium, magnesium and silicon, as a result of incorporating into a standard diet 20 Gm of regenerated cellulose a day.

SUMMARY AND CONCLUSIONS

1 A balance experiment was conducted on eight subjects for the purpose of determining the laxative efficacy of regenerated cellulose and its influence on mineral balance. An adequate diet was given for a five day control period plus preliminary and collection periods to total nine days in all. The same diet plus 20 Gm of cellulose a day was given for a five day test period, plus preliminary and collection periods.

2 Twenty grams of the regenerated cellulose a day is definitely laxative, as evidenced by (1) increased weight of fecal material evacuated, (2) increased fecal

moisture, and (3) increased number of defecations, during the test period.

3 Cellulose ingestion caused a tendency toward increased excretion of nitrogen and a definite increase in the excretion of phosphorus, calcium and fecal total ash.

4 It is doubtful whether the laxative potency of the cellulose counterbalances its detrimental effect on mineral retention. The wisdom of giving a high roughage diet to children and subjects under conditions of marginal mineral intake is severely questioned.

5 These data afford but slight basis for predicting possible injurious effects of cellulose products when they are eaten over a long period of time.

THE FORMATION OF CALCULI IN URETHRAL DIVERTICULA OF THE FEMALE

REPORT OF A CASE

CHARLES H. DEFT SHIVERS, M.D.

Associate Professor of Urology, University of Pennsylvania Graduate School of Medicine, Chief of Urological Department, Atlantic City Hospital and Atlantic City Genito-Urinary Clinic

AND

CHARLES J. COONEY, M.D.

First Assistant in the Department of Urology, Atlantic City Hospital, ATLANTIC CITY, N. J.

Calculus, whether primary or secondary, in a diverticulum of the female urethra is a condition that has received very scant mention in the literature.

The rarity of calculus in this location is due to several quite obvious reasons, the chief one being that vesical calculus per se is comparatively uncommon in women and that when it does occur a stone, even of considerable size, will usually pass naturally from the bladder. This is possible because the female urethra is so short, straight and easily dilatable, as emphasized by Stevens.¹

However, if a diverticulum is present in the urethra a migratory calculus may easily lodge within it. Much less commonly a stone forms in one of these pouches and it is this type of case that we report.

The urethral diverticulum in the female consists of a pouch or cavity situated in the urethrovaginal septum usually about the middle third and communicating by a narrow, often valve-like opening with the urethra. The contents of the diverticulum usually consist of urine and pus, the occurrence of calculus being rare.

CLASSIFICATION OF URINE POCKETS

There are various classifications of urine pockets connected with the urethra but the most practical of these designates all such pouches as

1 True diverticulum of the urethra—a diverticulum formed by protrusion of all the layers of the urethral wall.

2 False diverticulum of the urethra—a circumscribed dilatation in which the muscularis shows a break in continuity and in which the submucosa and mucosa protrude.

3 Incomplete urethrovaginal fistula. Here the term diverticulum cannot properly be used, as this type arises from solution of continuity of all layers of the urethral wall, it is connected with the urethra and ends blindly in the urethrovaginal septum. However, for the sake

⁸ Total phosphorus was determined by the method of Pemberton & F. Volumetric Analysis, ed. 11 Philadelphia: P. Blakiston's Son & Co. 1924. Food and fecal samples were first wet ashed; urinary phosphorus was determined without first being ashed.

⁹ The calcium was determined according to the method described by Morris, H. P., Nelson, J. W. and Palmer, L. S. The Quantitative Determination of Calcium, Magnesium and Phosphorus in Foodstuffs and Cattle Excreta. J. Indust. & Engin. Chem. (analytical edition) 3: 164 (April 15) 1931.

¹⁰ Total ash was determined according to the official method of agricultural chemists.

¹ Stevens, W. E. Diseases and Abnormalities of Female Urethra. California & West Med. 26: 471-475 (April) 1927.

of convenience, the term urine pocket, as suggested by Jarecki,² can be used to designate any of these pouches connected with the urethra

ETIOLOGY OF DIVERTICULA

In the etiology of diverticula, injury to the urethral floor during labor or by instrumentation is probably the most common factor. During labor, pressure of the child's head against the symphysis pubis is said to cause a crushing of the muscularis of the urethra, permitting a subsequent hernial protrusion of the submucosa and the mucosa.

Closure of the ducts of urethral glands, retention cysts resulting, is an occasional cause. Suppuration and ulceration into the urethra is the next step, and inflammation is maintained in the sac thus formed by urine trickling in at each micturition.

Blood cysts, vaginal cysts and suburethral abscesses (gonorrheal) pass through similar changes and communicate with the urethra.

In all these pathologic processes the final breaking through into the urethra most often occurs following the trauma of parturition.

Many authorities question the congenital theory of origin, but Hoehne,³ a German writer, reported in 1924 a case of urethral diverticulum in the female containing a large calculus that had apparently formed in the diverticulum. This cavity was lined with smooth mucous membrane which showed two longitudinal slits, separated by a septum 3 mm wide, leading into the lumen of the urethra. In view of this peculiar type of confluence with the urethra, Hoehne regarded his case as one of congenital diverticulum. Hoehne thinks it possible that para-urethral ducts analogous to the prostate in man may also in some cases lead into the middle third of the female urethra.

A diverticulum with a double orifice leading into the urethra was reported once previous to Hoehne's case by Veit⁴ at Leipzig in 1897, although in that case the diverticulum contained no stone. Veit believed that the origin was congenital and suggested that the diverticulum might have originated from Gartner's duct.

Fig 1—Calculus showing approximate size and its relation to surrounding structures

Fromme⁵ discovered in one of his cases a supernumerary ureter opening into a urine pocket. He looked on this finding as a corroboration of Veit's views as to the congenital origin of at least some diverticula of the female urethra.

REVIEW OF THE LITERATURE

In our review of the literature we have found that up until 1899 thirteen cases of calculus in a diverticulum of the female urethra had been reported. These cases were all discussed in the excellent treatise on the subject by the French writers Quenu and Pasteau.⁶

Since 1899 we have been able to find nine cases reported, making a total of twenty-two cases.

Of these twenty-two cases the stone formed around a foreign body in three instances. In the cases in

Fig 2—Number 6 French ureteral catheter coiled in urethral diverticulum

which there was no foreign body as a nucleus, all but two were cases in which the stone originated above and during migration became lodged in the urethra, subsequently forming a diverticulum. Urinary symptoms were prominent, of course, in all the cases in which a migratory stone or foreign body figured.

Only two cases were found, to which our case should now be added, in which no previous urinary symptoms were present and in which the stone was formed in a preexisting pouch or diverticulum. One of the reported cases³ was apparently a congenital diverticulum and in the other case⁷ a cavity was left following rupture into the urethra of an abscess of the anterior wall of the vagina. Symptoms due to the calculus did not make their appearance until ten years later in Nicholich's case.

REPORT OF CASE

F. R., a Negress, aged 41, admitted to the gynecologic service of the Atlantic City Hospital, complained of pain in the vagina of one and one-half years' duration. The onset of this pain was rather sudden, the pain was steady and aching in character, with periods of remission and periods of aggravation. However, she was conscious of the pain at all times.

There were absolutely no urinary symptoms at any time. The patient experienced no frequency, burning or pain on urination. There was no difficulty in micturition and no nocturia. About two months after the onset of the first symptoms the patient discovered a small lump in the anterior vaginal wall. This slowly increased in size and gradually became more annoying. The discomfort was increased by defecation and by coitus and when the patient was in the sitting posture. At the time of admission to the hospital the pain on sitting was so pronounced that the patient had been forced to give up her occupation of seamstress.

The past history contained nothing of note except an operation performed in a New York hospital five weeks before the initial onset of the symptoms described. The right ovary

and the tube had been removed. However, the patient stated repeatedly that she had not had any urinary symptoms at this time or subsequently.

She had been married twenty-one years and had had several miscarriages but only one full term delivery. This had been thirteen years before the onset of the present illness and was a very difficult, prolonged labor in which forceps had been used.

The day after admission to the Atlantic City Hospital the patient was transferred to the urologic service. General physical examination was essentially negative. On vaginal examination a round mass could be palpated through the anterior wall of the vagina. This mass did not protrude into the vagina but could easily be felt in the region of the urethra. The small tumor was round, firm, slightly movable and quite tender.

A soft rubber catheter was introduced into the bladder without meeting any obstruction whatever in the urethra. The catheterized specimen of urine was straw colored turbid, and alkaline in reaction, with a specific gravity of 1.023. Neither sugar nor albumin was present, and the microscopic examination showed no pus cells, casts or red blood cells. No organisms were found in the urine.

A complete blood count on admission showed erythrocytes, 3,460,000, leukocytes, 5,300, hemoglobin, 70 per cent, color index, 1.0. The differential count was polymorphonuclear leukocytes, 41 per cent, small lymphocytes, 55 per cent, large lymphocytes, 2 per cent, eosinophils, 2 per cent.

The blood chemistry showed creatinine, 1.24 mg per hundred cubic centimeters, urea, 12 mg, and sugar 80 mg.

The coagulation time of the blood was six minutes.

The blood Wassermann and Kahn tests were negative.

Cystoscopy revealed an absolutely normal bladder. However, when the cystoscope was withdrawn into the urethra an opening into what appeared to be a diverticulum was seen on the left posterolateral wall of the urethra in about the middle third. A calculus could be distinctly seen in the pouch. The mucosa about the margins of the opening was normal in appearance, with no evidence of any inflammatory changes.

A plain roentgenogram was taken and a ureteral catheter then inserted into the pouch, after which 15 per cent sodium iodide was injected and another roentgenogram taken. The size of the pouch, the stone and its relations to the urethra and other structures are shown in the illustrations.

Fig 3—Diverticulum following the injection of a 15 per cent solution of sodium iodide through a ureteral catheter, showing approximate size of the pocket.

A diagnosis of calculus in a urethral diverticulum was made and five days later a suprapubic cystostomy was done for the purpose of diverting the urinary stream preparatory to removal of the stone and pouch.

The second operation was performed two weeks after the cystostomy. With the patient in the lithotomy position and a weighed vaginal retractor in place, a T shaped incision was made in the anterior vaginal wall, the crossed portion of the T being directly over the mass and the long portion of the T extending anteriorly. After the vaginal wall was incised the wall of the pouch was encountered and after the sac was freed

by careful blunt dissection the stone was removed and the pouch excised. The opening in the urethral wall was closed in one layer of interrupted sutures, fine chromic catgut being used. The vaginal wall was closed in the same manner except that number 2 chromic catgut was used.

The stone was analyzed with the following results. It was yellow, with reddish brown pigmentation, it was smooth and roughly oval, measuring 1.5 cm in length and 1.2 cm in greatest width, and weighed 1.145 Gm. Chemical analysis showed moisture, 19.5 per cent, organic debris, 2.5 per cent, tribasic calcium phosphate, 51.2 per cent, magnesium ammonium phosphate, 12.2 per cent, and trisodium phosphate, 8.8 per cent.

The stone gave no test for carbonates or urates and it will therefore be noted that it was composed entirely of the phosphates of calcium, magnesium and sodium.

We are indebted to Mr Herman Brown, chemist to the Research Institute of Cutaneous Medicine of Philadelphia, for this analysis.

The patient's convalescence was uneventful, the urethral and vaginal walls healing by first intention. On the sixteenth postoperative day French sounds (numbers 17, 20 and 24) were passed through the urethra with ease. There was no leakage of urine into the vagina at any time after the operation and on the eighteenth day the suprapubic tube was removed. The patient urinated with ease and without discomfort and was discharged as cured on the fiftieth day after operation.

She has been examined several times since leaving the hospital over a period of two years and the site of operation remains firm, with no tendency to fistula formation, and sounds up to and including number 28 French can be passed with ease. These examinations have included a cystoscopic and roentgenographic study of the upper urinary tract. This study proved to be negative.

SUMMARY

1 The formation of calculi in a diverticulum of the female urethra is a rare condition, only two authenticated cases, so far as we know, having been reported up to the present time.

2 We feel that the calculus in this case formed in a preexisting urine pocket. The patient's history is very definite regarding the entire absence of urinary symptoms, and a careful search of the literature failed to reveal a single instance of a migratory stone forming a diverticulum of the urethra, or lodging in a diverticulum that already existed, without causing urinary symptoms.

3 The etiology of the pouch is not certain. It may have been congenital, as its walls contained muscle tissue as well as the mucous and submucous coats. However, we are inclined to believe that the starting point in the pathogenesis was the trauma to the urethra caused by a difficult labor and instrumental delivery several years prior to the onset of the present trouble.

4 The treatment of these conditions is always surgical and is based on two principles: first, preliminary suprapubic drainage for the purpose of diverting the urinary stream, and, second, complete removal of the sac and repair of the urethral wall.

5 We feel that the excellent result obtained in this case was due to our strict application of these principles and also to the fact that the suprapubic tube was kept in place for eighteen days after the stone had been removed and the urethra repaired, thus preventing infection due to the urine and allowing firm union of the urethra to take place.

PURPURA HAEMORRHAGICA WITH
CEREBROSPINAL HEMORRHAGE

REPORT OF TWO CASES

ARTHUR J. GEIGER, MD

Assistant Resident Physician New Haven Hospital
NEW HAVEN, CONN.

Although textbooks usually refer to the occurrence of cerebrospinal bleeding in purpura haemorrhagica, the association appears actually to have been recorded infrequently by clinicians and pathologists. Since Wagner's¹ comprehensive report in 1886, in which ten cases are collected, only nine additional scattered references comprising fifteen cases have been found.²

Case 1 in the present report would seem especially interesting in that the patient, who had purpura haemorrhagica, suffered two attacks of hemorrhage in the central nervous system and recovered from the first of these attacks under relatively simple treatment.

CASE 1—History.—O. A., an Italian housewife aged 24 admitted to the New Haven Hospital through the dental dispensary, April 27, 1932, complained of toothache and bleeding gums of two weeks' duration. For four months she had noted an unusually copious menstrual flow and a tendency to bruise readily. Two weeks before admission a persistent oozing of blood from the gums set in, and during this period the patient suffered several nosebleeds. She had vomited small clots of blood on a few occasions during the last week. There had been no other gastro-intestinal and no joint symptoms. Tarry stools were noted only since the day before admission.

The patient had gone uneventfully through childbirth eighteen months before. Her menses had frequently been irregular but always moderate in flow. In January and February, the first two months of the illness, the menstrual flow was suddenly doubled in volume and duration. In March and April there was amenorrhea.

Because of poverty the patient could seldom afford meat, and she had eaten practically no fresh fruit or vegetables for a year.

There was no history of hemorrhagic disease or of tuberculosis in the family. The mother, who was diabetic, had recently died of "blood poisoning."

Examination.—The patient was rational, alert and not acutely ill; the vital signs were normal. The skin and mucous membranes were pale. Her breath was foul, and the tongue was coated brown with old blood. The gums were blue but not spongy, and blood oozed freely from the gum margins around many of the badly carious teeth. A few petechiae were found on the soft palate and on the left palpebral conjunctiva. One small retinal hemorrhage was seen. Over the trunk and limbs were scattered numerous old and recent ecchymoses and several palpable subcutaneous hemorrhages. The spleen was uncertainly palpable. There were no neurologic nor other abnormalities. Pelvic examination confirmed the impression of a three months' pregnancy.

The blood count revealed a moderate anemia with 60 per cent hemoglobin and 3,440,000 red blood cells per cubic millimeter, of which 8 per cent were reticulocytes. Platelets numbered 90,000 per cubic millimeter. The bleeding time was six and one-half minutes; the coagulation time was eight minutes by the test tube method, and the clot showed poor retractility.

Lizier E. Riforma med. 48: 552-57 (April 9) 1932.

The guinea test was moderately positive on the stool and negative on the urine. The Kahn test of the blood was negative.

Course in Hospital.—The patient was started on a diet high in vitamin content and given 12 cc. of a 50 per cent solution of iron and ammonium citrate daily by mouth. During a period of twelve days on this treatment there was only a slight transient diminution of the bleeding.

On the third day the patient complained for the first time of the severe frontal headaches which were to recur with excruciating violence for almost a month. The hemorrhagic phenomena again increased and at the end of the first week nausea and the daily vomiting of fluid and clotted blood set in. On the twelfth day the patient received the first of six transfusions, each of 250 cc. of whole blood, which were given at daily intervals. Although a moderate improvement in the degree of anemia took place, there was no apparent influence on either the bleeding or the symptoms. In fact, during the series of transfusions the patient began to complain of aching pains in the legs, which soon became agonizing. Because of the severe persistent headaches and a slight rigidity of the neck, lumbar puncture was performed at the end of the third week. The fluid obtained was thick and dark red and contained 8,350,000 red blood cells per cubic millimeter. A repeated puncture at a higher level confirmed these observations. The withdrawal of fluid was followed within twenty-four hours by great amelioration of the headache, the vomiting and the pains in the legs, and with each of the four successive daily drainages the fluid cleared rapidly and the symptoms improved steadily. For two days following the last tap the patient felt unusually comfortable, but on the third morning her right thigh exhibited constant involuntary twitching movements of the adductor and flexor groups of muscles, this continued for three hours. Although the right knee jerk was hyperactive, no other pyramidal signs were elicited. At lumbar puncture the next day a clear fluid was obtained.

During the next few weeks all symptoms subsided rapidly, the bleeding stopped and the patient improved in strength and weight. Just before discharge from the hospital, seven weeks after admission, an abscessed tooth was extracted without unusual hemorrhage. At this time the bleeding time was normal but platelets were still noted to be rare in the blood smears.

Follow-up.—During the four succeeding months the patient returned frequently to the outpatient clinic and throughout this period she exhibited no purpuric signs. In November 1932 she was delivered easily and with a blood loss not exceeding 350 cc. On this admission the bleeding and clotting times and the clot character were normal, and platelets were abundant in the blood smears.

Two months after delivery purpuric spots reappeared in the skin, bleeding of the gums returned and the patient suffered spells of vertigo and fainting associated with excessive menstrual bleeding. The blood smear again contained only rare platelets. Although splenectomy had been advised repeatedly and was now urged, the patient postponed decision. On the evening of March 1 she felt vaguely ill, complained of headache and vomited several times. On attempting to arise during the night she found herself paralyzed on the left side.

Readmission.—The patient was stuporous on arrival at the hospital the next morning, but she was rational when aroused and complained of headache. The left arm and leg were paralyzed and reflexes could not be obtained. The spine was not stiff. Several fresh retinal hemorrhages were seen, blood oozed from the mouth and vagina and purpuric spots and subcutaneous hemorrhages were profusely scattered over the body.

The red blood cell count was now 4,100,000 and the hemoglobin 60 per cent. No platelets were seen in the blood smear. The bleeding time was eight and one-half minutes.

In spite of an intramuscular injection of 30 cc. and a transfusion of 450 cc. of whole blood, the patient sank steadily into coma; the respirations became Cheyne-Stokes in character, and the right arm exhibited occasional clonic convulsions. Later in the day all four limbs, especially those on the right, assumed an extensor type of rigidity, the neck grew slightly rigid, plantar stimulation evoked flexor responses and the right pupil

become dilated and fixed. With deepening coma and a temperature rising to 104 F, respirations ceased early the next morning. Shortly before death the blood pressure was recorded at 160 systolic and 75 diastolic, the pulse rate had continued all day in the vicinity of 80.

Because of the probably active cerebrospinal bleeding and in the absence of signs of definitely increased intracranial pressure lumbar puncture had been considered contraindicated. Permission for necropsy was denied.

Among the thirty-six cases of purpura haemorrhagica seen at the New Haven Hospital since 1922, of which five ended fatally, in only one other were there manifestations of presumable cerebrospinal hemorrhage. It is described briefly.

CASE 2—History—C. O., a woman aged 24, Irish, a telephone operator, walked into the hospital on the afternoon of Aug. 17, 1925. She complained of bleeding gums and of purpuric spots on the face which had developed insidiously during the preceding month. Except that her last menstrual period had been profuse and had lasted five days instead of the usual three, she had noted no other signs of illness. Her health in the past had always been good.

The patient's father had died of Bright's disease, her mother and three siblings were well.

Examination—The patient was fairly well nourished. Although her skin was pale, she did not look very ill. She was bleeding from the gums and a moderate number of petechiae were scattered over the face, the thorax and the legs. The spleen was not felt. Except for a pulse rate of 100, the vital signs were normal.

The red blood cells were diminished to 3,600,000 per cubic millimeter, the hemoglobin was 58 per cent. The bleeding time was prolonged to ten minutes and the clotting time to fourteen minutes. The blood clot showed no retraction at the end of twenty hours. An impression that the platelets in the blood smear were diminished in number was confirmed by a count of 120,000 per cubic millimeter. There was gross blood in the urine. The blood Kahn test was negative.

Course—During the night the patient became comatose. In the morning she was bleeding slowly from the mouth, the nose and the vagina. Several large subcutaneous hemorrhages had appeared along with an increased profusion of purpuric spots. A few retinal hemorrhages were seen.

At noon there occurred several generalized convulsions during which the head was turned to the right and both arms were drawn up in flexion over the chest.

An attempt at transfusion met with difficulties and only 160 cc of citrated blood could be given. Coma deepened rapidly. Cheyne-Stokes respiration set in, and death ensued in a few hours.

COMMENT

From a study of published reports and from his own unusual experience of five cases, Longcope² observed that in purpura the hemorrhages in the central nervous system are usually multiple and that they vary in size from petechiae to large extravasations of blood, which may cover an entire cerebral hemisphere or involve several lobes. Symptoms and signs of the hemorrhage will obviously vary widely, since they depend on the size and the location of the lesions, but most cases appear to fall into several easily discernible groups. One group presents chiefly the appearance of meningitis, with slight focal or generalized neurologic signs. Another group and probably the largest exhibits definite localizing signs, among which hemiplegia is common. A third group includes cases of coma, sometimes with convulsions. An occasional case offers no definite neurologic symptoms or signs, and the hemorrhage is discovered unexpectedly at necropsy.

In the former of the foregoing two cases it would seem probable that the bloody spinal fluid obtained

by lumbar puncture during the first hospital admission arose from meningeal bleeding. The sudden development of hemiplegia associated with recurrence of active purpura some months later suggests that an extensive hemorrhage occurred within the cerebrum at this time.

In the second case the period of observation was unfortunately too brief for satisfactory neurologic study, but the coma, convulsions and rapidly fatal course in the absence of localizing signs suggests either an intracerebral or a large subdural hemorrhage.

Although cerebrospinal hemorrhage in purpura usually implies a fatal prognosis, recovery from even large hemorrhages has been reported before (Wagner,¹ Longcope,² Meyer and Parker³). Recoveries seem commonest in the "meningitic group", none have been noted in the group with hemiplegia.

Clinical Notes, Suggestions and New Instruments

CALCIUM METABOLISM IN IDIOPATHIC HYPOPARATHYROIDISM

ALFRED GOERNER, M.D. AND GEORGE SAMUELSEN, BROOKLYN

Although Salvesen¹ concluded from his work on parathyroidectomized animals that the resulting calcium deficiency in the blood was due to an increased excretion of this element especially in the intestine, Greenwald and Gross² shortly found conclusive evidence that calcium excretion was in fact decreased after parathyroidectomy. They³ also showed that administration of the hormone increased the amount of the metal to be excreted. The latter result is directly opposed to Salvesen's idea that the internal secretion of the parathyroid aids in the absorption of calcium. Albright and Ellsworth,⁴ in their study of calcium metabolism in a person having an idiopathic hypoparathyroidism confirmed Greenwald's results. This study is interesting in that most other studies of calcium metabolism in parathyroid deficiency were made on animals with the glands removed or on human beings whose deficiency set in after a thyroidectomy. Albright, Bauer, Ropes and Aub⁵ also showed that, in normal persons on an inadequate calcium intake, the administration of the specific hormone increases urinary output of this element without materially changing the fecal excretion.

Greenwald⁶ observes that in parathyroid deficiency the calcium apparently leaves the blood to be deposited in the tissues perhaps the bones. Certainly no increased density of the bones was observed by Albright and Ellsworth⁴ in a boy with a long-standing idiopathic hypoparathyroidism, nor was there any found in the following instance. It is also interesting to note that they observed transient loss of consciousness in the individual under study and thus at times when he showed a low serum calcium, a similar reaction took place in the subject of our investigation at such times.

REPORT OF CASE

A girl, aged 18, entered the hospital, Jan. 9, 1933 for the relief of tetany occurring usually at the time of menstruation.

The family history was apparently of no significance. She stated that at the age of 4 years she had scarlet fever and, at the age of 7, otitis media and mastoiditis. A tonsillectomy was performed at 10 years because of recurring sore throats. Before the age of 10 she had had measles and chickenpox. Menstruation began at 14 with scanty flow and some dysmenorrhea. She began to have attacks of tetany at this time and described typical hand position and other signs. During 1930 she was treated at the Bellevue Hospital for fainting spells which lasted from half a minute to five minutes but after several weeks the attacks set in again. In April, 1932 she

* In these tables from the first to the sixth day inclusive the patient was on a diet of 2 liters of milk a day from the seventh to the twelfth day inclusive 20 units of parathyroid extract a day was given.

entered the Long Island College Hospital for relief of tetany and fainting spells. At that time she showed a positive Chvostek sign on both sides and a positive Trousseau sign. The spinal fluid showed 8 mm of pressure and a cell count of 3. A blood study showed secondary anemia. The serum calcium was 5 mg and the blood phosphorus 10 mg per hundred cubic centimeters. The spinal fluid and blood Wassermann tests were negative. After the patient was placed on parathyroid extract the symptoms disappeared and the serum calcium and phosphorus returned to normal.

She was discharged and placed on a high calcium regimen plus viosterol. June 14 she returned to the medical service for treatment of fainting spells on examination Chvostek's and Trousseau's signs were positive and the serum calcium was 6.6 mg per hundred cubic centimeters. In October she entered the hospital for the same reason the serum calcium being 6 mg. Her repeated entrance into the wards allowed

Total 4, 5 and 6	5.204	0.349	8.901	5.553	
Total 10, 11, 12	5.606	0.888	9.002	6.404	

the trial of such measures as large doses of various calcium salts, ammonium chloride and viosterol, but the prophylactic use of these was of little avail in influencing the abnormal calcium metabolism. It was found that prophylactic doses of parathyroid extract alone prevented the return of tetany and loss of consciousness. Roentgenograms showed no increased density of the bony structures. The basal metabolic rate was normal.

In order to work out the calcium metabolism on this patient she was placed on a diet of 2 liters of milk a day. During a period of three days no tests were made but on the following three days the feces, urine and milk were analyzed for calcium content. This was done by igniting a definite amount of the substance to be tested dissolving the ash in hydrochloric acid neutralizing it with ammonium hydroxide, slightly reacidifying it and precipitating the calcium with ammonium

oxalate solution. The precipitate of calcium oxalate was ignited and weighed as calcium oxide.

This test was carried out when the patient was receiving no medication and repeated when she was receiving parathyroid extract.

The accompanying tables give the results of the analyses.

During the period comprising the seventh to the twelfth day inclusive the patient was receiving 20 units of parathyroid extract a day. In terms of the element calcium, the balance is shown in table 2.

It will be seen from the total calcium excreted in the feces for the first three days that it differs but slightly from the second three day period whereas the calcium excreted in the urine for the second period is more than double that of the first three days.

SUMMARY

The calcium metabolism of a young woman having an idiopathic hypoparathyroidism was studied. It being found that there was a positive calcium balance that was reduced by the administration of parathyroid extract.

The increased excretion of calcium as a result of the use of parathyroid extract appeared to be chiefly by way of the urine, very slight if any change took place in the fecal calcium content after the use of the hormone.

What becomes of the calcium stored in hypoparathyroidism is still an open question for apparently x-rays do not show increased density of the bones although this method may not be sufficiently delicate to show the amount that may be stored there.

350 Henry Street

EFFECT OF INTRAVENOUSLY INJECTED DEXTROSE ON THE RATE OF PROPULSION IN THE SMALL INTESTINE

J. P. QUIGLEY, PH.D. AND WILLIAM H. HIGHSTONE, B.S.
CLEVELAND

When oral alimentation is inexpedient or impossible, the intravenous administration of dextrose is often desirable to supply nutrition and to prevent or relieve acidosis and the like. This situation is especially prone to occur in patients having actual or latent gastro-intestinal disturbances. Clinicians may hesitate in the employment of intravenous dextrose if they have reason to believe that this procedure has a tendency to cause ileus. In spite of the need for information regarding the action of intravenous dextrose on intestinal motility investigations on this subject have been rare.

In 1924 Bulatao and Carlson¹ reported that in dogs intravenous injections of 50 per cent dextrose caused an inhibition of gastric hunger contractions. This conclusion has frequently been extended by inference to other portions of the gut. The belief has thus become current that intravenous injections of dextrose inhibit the entire gastro-intestinal tract. This is in spite of the observation of Hughson and Scarff² that gastro-intestinal motility was augmented in the cat by the intravenous administration of 25 per cent dextrose. Quigley and Hallaran³ investigated the subject and by means of the balloon method obtained definite evidence that the intravenous injection of doses ranging from 1 to 25 Gm of dextrose did not inhibit the empty stomach, the ileum or the colon of the normal dog. It was established that a transient inhibition may be produced if the injection is given rapidly or the animal is otherwise disturbed by the procedure. The absence of inhibitory action on gastric hunger motility was likewise demonstrated by

The expenses of this investigation were defrayed in part by a grant from the Therapeutic Research Committee of the American Medical Association.

From the Department of Physiology, Western Reserve University School of Medicine and the Department of Physiology and Pharmacology, Northwestern University Medical School.

3. Quigley, J. P. and Hallaran, W. R. The Independence of Spontaneous Gastro-Intestinal Motility and Blood Sugar Levels. *Am. J. Physiol.* 100: 102-110 (March) 1932.

Mulinos⁴ Gage, Ochsner and Cutting⁵ recently reported that intravenous dextrose leads to a transient inhibition of the normal or obstructed ileum. They further reported that, if administered after insulin, dextrose produced augmented motility. These statements were so contradictory to our observations that we deemed it advisable to study the problem by a different technique.

In the ileus problem the effect of dextrose injections on the propulsive efficiency of the intestine is at least as important as the effect on nonpropulsive motility. It was therefore considered desirable to investigate the question from the standpoint of propulsion activity, especially since the balloon method as usually employed does not yield such information. We have studied the intestinal propulsive rate by the bolus method⁶, i. e., by repeatedly determining the time interval required for a small pliable rubber bolus to be pushed through a loop of the

TABLE 1—Number of Experiments in Which Propulsive Motility Was Inhibited Stimulated or Unchanged

Quantity of Dextrose		Effect During First 20 Minutes			Effect During 20.00 Minute Interval		
		Inhibition	Stimulation	Unchanged	Inhibition	Stimulation	Unchanged
100 cc 5% solution		2	3	2	3	2	2
100 cc 10% solution		3	8	1	2	7	3
30 cc 25% solution		0	3	3	0	4	2

intestine. Using four well trained unanesthetized dogs lying at ease on mattresses, we performed twenty-five experiments. To determine the normal propulsion rate we repeatedly introduced the bolus into the oral end of a jejunal Thury-Vella loop and timed its reappearance at the anal end. After suitable control propulsion rates were obtained, we carefully introduced the dextrose solution into the small saphenous vein and continued the determination of the propulsion rate. Cognizance was taken of the detailed precautions necessary to prevent the reactions that sometimes result after improper intravenous dextrose administration. The results of our bolus studies support the conclusions reached in our balloon experiments.³ Dextrose can be administered without decreasing propulsive activity; however, if the animal is disturbed by the injection or subsequently becomes restless, a lengthening (usually transient) of the propulsion time may be observed. On the other hand our experiments show that intravenous dextrose may even shorten propulsion time. This tends to support the statement of Hughson and Scarff⁷ that hypertonic dextrose, like hypertonic sodium chloride, augments motility. However, the changes in propulsion rate that did occur after dextrose were usually small in magnitude.

The results obtained in two typical experiments follow: (1) The normal rate for the passage of the bolus through a 9 inch loop of jejunum was in repeated control tests 3 3 3, 3 3 minutes, after 30 cc of 25 per cent dextrose it was 3 3, 2 3 1, 4, 2 3 3, 4, 4, 3, 3 minutes, (2) the normal rate 5 5 5 5 minutes, after 100 cc of 10 per cent dextrose 5 3 4 3, 4, 4 4 4 4 minutes. The data of our entire investigation are summarized in the accompanying table.

CONCLUSIONS

Intravenous injections of dextrose usually produce no pronounced change in the rate at which a bolus traverses a loop of the dog's jejunum. With hypertonic solutions however, augmented propulsion may follow. A delay in propulsion appears to be an atypical response. The contention that in latent or actual ileus intravenous dextrose properly prepared and administered is contraindicated because of an inhibitory action on the intestine appears to be unwarranted.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
H. A. CARTER Secretary

PARASEPT NOT ACCEPTABLE

Dr. Schlosser's Heat Therapy, 302 West Eighty-Seventh Street, New York City, submitted a product called Parasept to the Council for consideration. The firm claims that this product is an antiseptic paraffin composition and is a good method of applying heat therapeutically to the body. A technique of application is proposed. First, olive oil is rubbed on the affected part. By means of a suitable brush, melted Parasept is applied quickly in layers until a thickness of approximately one-third inch has been obtained over the part. So covered with hot composition the part is wrapped in sheets and blankets and kept in that condition for approximately thirty minutes.

The Council investigated Parasept, following the directions as prescribed by the manufacturer. On first contact of the brush the burning hot sensation was soon replaced by a pleasant feeling of warmth. The composition was left on for the prescribed time. When the Parasept was removed the skin was warm and hyperemic, and this state persisted for about two and one-half hours after treatment.

Parasept was used in a clinic by a Council investigator on several patients, whose conditions were diagnosed as arthritis, myositis and neuritis. However, no relief of symptoms was reported that could not be explained by the physiologic action of heat. The investigator reported that he had been using paraffin applications for several years and that there was apparently no difference between the effects of Parasept and ordinary Paraffin.

Although the Council has recommended the therapeutic value of warm paraffin as a method of applying heat, it voted not to accept Parasept, because the advertising matter and descriptive literature contain misleading statements and because the Council's investigation indicated that the product did not possess any more therapeutic efficacy than that obtained from ordinary warm paraffin.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH Secretary

OLEOTHESIN NOT ACCEPTABLE FOR N. N. R.

Oleothesin is manufactured by the Oleothesin Company of Buffalo, N. Y., and patented in the name of Oscar Hayen Stover of Buffalo (#1,907,392, May 2, 1933). It has been the subject of inquiry to the Council by reason of recent advertising. While the advertisements are noninformative regarding composition, they are not reticent concerning the alleged therapeutic attributes of the product. In fact, this broad, all-inclusive claim is made: "safe certain SURFACE ANESTHETIC." Eleven specific uses for the product appear, two of which are to

Desensitize skin at site of needle puncture particularly on children
Control pain associated with boils and carbuncles

Inquiry was made of the manufacturer whether or not the product was of secret composition and if not, a quantitative statement of its formula was requested. The reply denied secrecy and set forth the following formula:

	% by wt.
Procaine base	17.2
Alcohol	6.0
Olive oil	76.7
Lanolin	
Cresol	0.1
Flavors	

This is a formula the prescription for which might have been written on any suitable occasion by any practitioner from Maine to California. However, on May 2, 1933, a patent was issued

and so the mixture became an original, protected invention and any one writing such a prescription after that date, regardless of how frequently he had been using it before, would be liable to prosecution under the United States laws for patent infringement or would be obliged to contest the patent in court if the manufacturer so chose.

The increased penetrating power (through mucous membranes) and the solubility in oils and fats of procaine base, as compared with the hydrochloride, have been known since the work of O. Gros (in 1910) and verified by A. Laewen (1910, 1912) and Sollmann (1918). The base does not penetrate the intact integument and hence would be of no appreciable value in relieving the pain of boils, carbuncles or needle puncture. In a booklet entitled "Pharmacology and Technique" it is ingeniously implied that the product is the answer to a study of fifty years' duration.

There has been a continuous search since Koller's use of cocaine in 1884 for a drug to be used as a topical anesthetic possessing the ability to penetrate mucous membranes yet having low toxicity.

If Oleothesin is that long sought drug then the search should have ended twenty-three years earlier than the granting of the patent, with the publication of the actions and properties of procaine base by the aforementioned investigators. The product clearly represents another attempt to push a mixture of a thoroughly investigated, familiar and time-honored drug as something new, original and epoch making. It has been said that if common sense dictated the granting of patents such a mixture would not be patentable.

The Council declared Oleothesin not acceptable for New and Nonofficial Remedies because it is an unoriginal mixture of well known substances marketed under a misleading, suggestive trade name with no statement of its composition and under therapeutic claims that are too inclusive, exaggerated and unwarranted.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

CELLU BREAKFAST CRISP

A SPECIAL PURPOSE BREAKFAST FOOD FOR DIETS LOW IN SUGAR AND STARCH
(SWEETENED WITH SACCHARIN)

Manufacturer—Chicago Dietetic Supply House, Inc., Chicago

Description—A cereal substitute of little nutritive value prepared from washed bran, commercially pure powdered cellulose, mineral oil, India gum, sodium chloride, sodium bicarbonate, baking powder and saccharin (not more than 1 gram of soluble saccharin per 7½ ounce package but omitted when sold in states forbidding its use).

Manufacture—The dough is prepared as described under Cellu Wafers (THE JOURNAL, Feb 10, 1934, p 457). The soft dough is machine pressed into strands which are dried on large trays dried in moderately hot ovens and packed in wax-lined cartons.

Analysis (submitted by manufacturer) —	per cent
Moisture	2.8
Ash	4.2
Fat (essentially mineral oil) (ether extraction method)	27.7
Protein (N × 6.25)	3.9
Crude fiber	22.6
Available carbohydrates (calculated as starch—diastase method)	2.3
Unavailable carbohydrates other than crude fiber (by difference)	36.5

Calories—0.3 per gram 9 per ounce

Claims of Manufacturer—Cereal substitute of low food value, for adding bulk to low carbohydrate diets.

GOLDEN CROWN BRAND WHITE SYRUP

Manufacturer—Stewart, Son and Company, Baltimore

Description—A table syrup, corn syrup flavored with sucrose syrup.

Manufacture—Corn syrup and sucrose in definite proportions are mixed, heated to 74 C, filtered and automatically packed in cans.

Analysis (submitted by manufacturer) —

	per cent
Moisture	23.9
Ash	0.4
Fat (ether extract)	0.0
Protein (N × 6.25)	trace
Reducing sugars as dextrose before inversion	30.2
Dextrose (by fermentation method)	10.1
Sucrose (estimated from reducing sugars before and after inversion)	5.0
* Maltose (by fermentation method)	20.1
Dextrins (by difference)	40.5
Acidity as HCl	0.0
Sulphur dioxide	0.0005

* Indust. & Engin. Chem. 25: 98, 1933

(No methods are available for accurately determining the composition of syrups of this nature, therefore the foregoing analysis is roughly approximate.)

Calories—3 per gram, 85 per ounce

Claims of Manufacturer—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

ORANGE CRUSH CARBONATED BEVERAGE

(CARBONATED WATER, SUGAR, FRESH ORANGE JUICE, FLAVOR OF LIME, FRUIT ACID, ARTIFICIALLY COLORED)
CONTAINS ½% OF 1% SODIUM BENZOATE

Manufacturer—Orange Crush Company, Chicago

Description—Carbonated beverage prepared from carbonated water, sucrose, juice pulp and oil from entire oranges, citric acid (lemon juice), sodium benzoate (0.05 per cent) and United States Department of Agriculture certified color.

Manufacture—Oranges larger or smaller than standard for Eastern markets are mechanically washed, scrubbed, sorted, inspected, crushed by machine and all pulp, juice and part of the oil of the peel are removed, cane sugar is added. Concentrated lemon juice and United States Department of Agriculture certified food color are added to adjust the acidity and color. The mix is kept in paraffin lined barrels in cold storage until shipped each week to bottling plants, where it is mixed with carbonated water, sugar syrup and sodium benzoate and bottled.

Analysis (submitted by manufacturer) —

	per cent
Moisture	84.4
Total solids	15.6
Ash	0.04
Fat (ether extract)	0.02
Protein (N × 6.25)	0.6
Reducing sugar as invert sugar	2.0
Sucrose (copper reduction method)	11.9
Crude fiber	0.01
Carbohydrates (by difference)	14.6
Titratable acidity as citric acid	0.27
Sodium benzoate	0.05

Calories—0.6 per gram 17 per ounce

Vitamins—Biologic assay shows that the final beverage retains essentially the vitamin C content of the orange juice used. 1 cc of orange juice to 21 cc of beverage.

Claims of Manufacturer—A refreshing and wholesome beverage.

HEIMAN'S BRAND SPARKLING CRYSTAL WHITE SYRUP

Distributor—Heiman Grocery Co., Trenton, Mo.

Packer—Bliss Syrup & Preserving Co., Kansas City, Mo.

Description—A table syrup, corn syrup sweetened with sucrose syrup and flavored with vanilla, the same as Bliss Pancake Crystal White Brand Syrup (Blend of Corn Syrup and Cane Sugar Syrup Flavored with Vanilla) (THE JOURNAL, Nov. 18, 1933, p 1635).

HOSPITAL SERVICE IN THE UNITED STATES

THIRTEENTH ANNUAL PRESENTATION OF HOSPITAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The desire to have this year's census of hospitals the most complete yet taken by the Council has been realized in a gratifying degree, thanks to the response of superintendents and others. The mass of classified information presented in these pages covers more than 97 per cent of all the recognized hospitals and sanatoriums in existence and represents more than 99 per cent of their aggregate bed capacity.

The census was begun late in 1933 and the reports were turned in near the end of 1933 and early in 1934.

There are now 6,437 hospitals having a capacity of 1,027,046 beds and 52,464 bassinets.

The increasing capacity of all hospitals, which has been mounting steadily at the rate of from 20,000 to 25,000 beds annually for the past twenty-five years, showed a slack in speed in the 1933 census for the first time, the increase in capacity for that year being only 12,692 beds over the preceding census.

Last year 7,037,982 persons, or 1 in 18, were bed patients in hospitals.

HOSPITAL CAPACITY AHEAD OF POPULATION

The above diagram reveals the rapid and striking increase in the number of hospital beds in contrast to the steady growth of population. Each of the vertical columns with dates at bottom represents a 10 year period. Each of the parallel horizontal lines represents 10,000,000 population or 100,000 hospital beds. Since around 1890 the growth in hospital beds has been quite marked as is shown by the abrupt upward curve. For approximately 25 years hospital beds have shown a steady regular increase at the rate of 20,000 to 25,000 beds per year until 1932. During 1932-33 the increase was only 12,692 beds. This slight slowing down in rate of increase of hospital beds during the past year reflected in the changed direction of the curve at the upper right hand corner of the diagram if allowed to continue for a few years would result in a more reasonable yet adequate supply of hospital beds in relation to population.

The figures obtained, therefore, reflect very nearly the conditions prevailing in hospitals for the calendar year 1933. In general the reports give evidence of having been prepared with greater accuracy than heretofore.

The list of hospitals on pages that follow gives the name, classification, approval and other data regarding all registered hospitals and related institutions rendering certain types of true hospital service.

The purpose of this article is, through the listing of hospitals and the compiled statistics, to furnish a source of information, statistical and otherwise. The following paragraphs are designed to present some of the most obvious facts.

There was an average of 216,775 idle beds, of which 155,021 were in general hospitals.

The total patient days in all hospitals numbered 295,748,915. The rate of occupancy in general hospitals was 59.9 per cent.

The average length of stay in general hospitals was fourteen days. It was thirteen days in church, individually owned, and nonprofit corporation hospitals.

The annual census finds that 709,276 babies were born in hospitals, as compared with 710,884 for the preceding year. One third of all births were in hospitals.

(Continued on page 1010)

(Continued from page 1005)

A change of bed capacity during the year was reported by 1,498 hospitals—an increase in 802 and a decrease in 696.

The capacity of hospitals in the United States has doubled in the past twenty years. In 1914 there were 532,481 beds, in 1933, 1,027,046 beds.

Total beds added in the last ten years were 271,325, of these 222,525 were built with public funds and 48,800 with private funds.

In the past ten years, from 1923 to 1933, governments, federal, state and local, added to their hospital facilities more than four and one-half times as many beds as nongovernment agencies.

However, 76 per cent of the capacity of all governmental hospitals is for treatment of tuberculosis and mental diseases.

The number of patients in all hospitals has not been diminished by the depression, in 1929 the average census was 726,766, in 1933 it was 810,271. In hard times more people go to tax-supported hospitals and fewer to other types of institutions.

Governmental hospitals were 88.9 per cent filled in 1929 and 90.1 per cent in 1933, nongovernment hospitals were 64.6 per cent filled in 1929 and only 55.3 per cent in 1933.

Idle beds for several past years have been as follows:

1923	202,550
1929	180,367
1930	192,487
1931	198,719
1932	205,909
1933	216,775

Hospitals have sent in the names of 126,261 physicians (duplicates eliminated) who have hospital connection.

Physicians comprise 36 per cent of all hospital superintendents, nurses 40 per cent and laymen 24 per cent.

Röntgen-ray departments number 4,677, with 3,487 run by physicians, 892 by other persons, the remainder not specified.

Among the 4,324 hospital laboratories, 2,878 are directed by pathologists or other physicians, 1,089 by other persons, remainder not specified.

In 1933, 1 person in 13 was an outpatient in a hospital, in 1929, 1 in 18, and in 1921, 1 in 35.

At the end of 1933 there were 677 approved hospitals offering 6,074 internships and 370 offering 2,438 residencies.

UNOCCUPIED BEDS IN HOSPITALS

Comparisons of bed occupancy between 1929 and 1933 are made in the accompanying table. The reasons for selecting the years 1929 and 1933 for comparison are obvious. The number of vacant beds in each of the several groups of hospitals as an average does not reflect conditions in individual hospitals but should be interesting facts for the consideration of those who may be contemplating the building of additional hospitals as well as those who bear the burden of taxation or philanthropy necessary to support existing hospitals.

Among the nongovernmental groups, church hospitals which maintained 37,785 idle beds in 1929, had 52,219 in 1933. Similarly, the other independent hospital associations carried 54,794 idle beds in 1929 and 71,305 in 1933. These nongovernmental hospitals are nearly all general which helps to explain the compara-

tively low rate of occupancy in hospitals not maintained by taxation.

The number of idle beds in general hospitals has reached the astonishing number of 155,021, having increased from 123,025 since 1929.

Unoccupied Beds in Hospitals

(I) According to Ownership or Control	Unoccupied Beds (Average)			
	1929	1930	1932	1933
Federal	13,863	13,052	16,161	18,969

Hospital departments of institutions	9,148	9,717	8,793	8,591
All other hospitals	2,364	2,197	1,089	1,175
Total unoccupied beds—all hospitals	180,072	192,457	205,909	216,775

OCCUPANCY OF HOSPITALS ACCORDING TO OWNERSHIP OR CONTROL

Table 1 shows occupancy in hospitals in 1933 by groups and it affords comparison with 1923. The groups under governmental hospitals are federal, state, county, city, and city-county, and the groups under nongovernmental hospitals are church, fraternal, industrial, individual or partnership, and independent associations.

Percentage of Beds Occupied in Hospitals According to Ownership or Control Showing Trend in Past Decade

	1923	1929	1930	1931	1932	1933
Federal	64.8	76.8	79.2	76.5	78.2	75.0
State	80.6	94.6	93.8	94.2	94.2	94.5
County	72.5	80.7	82.2	81.2	84.1	85.8
City	65.2	74.3	75.9	76.3	82.8	83.0
City-county	64.9	80.2	81.6	82.0	72.4	79.0
Governmental	79.4	88.9	88.8	88.7	89.8	90.1
Church	62.9	66.7	64.2	63.2	59.6	54.9
Fraternal	63.1	68.7	67.4	69.0	66.8	64.5
Industrial	53.7	54.4	53.1	48.2	47.7	44.4
Individual or partnership	59.9	54.2	51.7	48.7	45.6	41.1
Independent associations	64.0	60.9	65.4	64.3	61.3	58.0
Nongovernmental	69.8	64.6	63.2	61.9	59.2	55.3
All hospitals	73.1	80.1	79.8	79.6	79.7	78.8

In 1923 the only one of these governmental groups that showed an occupancy rate of more than 72.5 per cent was state hospitals, whose rate was 86.6 per cent. In 1933, not one of the governmental group showed less than 75 per cent occupancy, the figures for the latter year being federal, 75.0, state, 94.5, county,

85.8, city, 83.0, city-county, 75.5 The rate of occupancy for the entire governmental division advanced from 79.4 to 90.1

Among the nongovernmental groups, the average occupancy for all hospitals in the groups in 1923 was 62.8 per cent the lowest being industrial hospitals, 53.7, and the highest in the group being independent associations, 64.0 per cent In contrast, in 1933 the entire nongovernmental group had an occupancy of 55.3 per cent, the lowest being individual or partnership hospitals 41.1 per cent, and the industrial hospitals 44.4 per cent In 1933, church hospitals had an occupancy of 54.9 per cent, fraternal hospitals 64.5, and independent associations 58.5 per cent

Comparison between the rate of occupancy in any one year and that in other years may be readily made by reference to accompanying tables The rate in all the registered hospitals taken together advanced in ten years from 73.1 per cent to 78.8 per cent The rate of occupancy in all hospitals reached its highest peak in 1929, with 80.1 per cent The rate of occupancy in all hospitals taken together is not seriously affected by depression except that in such times a larger proportion of the patients go to the tax-supported hospitals

SHIFT FROM NONGOVERNMENTAL TO GOVERNMENTAL HOSPITAL SERVICES

During the past decade the number of hospital beds under governmental control increased as follows

- (a) Federal, 40 per cent
- (b) State, 52 per cent
- (c) County, 73 per cent
- (d) City, 8 per cent
- (e) City-county, 94 per cent

Total government beds increase, 47 per cent

The average census increased 67 per cent in government hospitals

In contrast

- (a) Church hospitals increased 49 per cent
 - (b) Fraternal hospitals increased 7 per cent
 - (c) Industrial hospitals increased 4 per cent
 - (d) Individual and partnership hospitals decreased 27 per cent
 - (e) Independent association hospitals increased 15 per cent
- Total nongovernment beds increased 17 per cent

During this time the average census in nongovernmental hospitals increased but 3 per cent

During the two years 1931-1933 the number of patients admitted to governmental hospitals increased 18 per cent, while those admitted to nongovernmental hospitals decreased 8 per cent

The total number of patients admitted to all hospitals is approximately the same for 1933 as for 1931, there being a decrease of 1.6 per cent

HOW HOSPITALS SHARED IN PATIENTS ADMITTED IN 1933

During the year covered by the present census, all registered hospitals admitted a total of 7,037,982 patients The proportion of this huge number of patients which each group of hospitals admitted is shown in the following tabulation

According to Ownership or Control

Federal	4.6 per cent	Church	24.9 per cent
State	6.8 per cent	Fraternal	0.5 per cent
County	5.7 per cent	Industrial	0.9 per cent
City	10.8 per cent	Individual or partnership	5.4 per cent
City-county	2.9 per cent	Independent associations	37.7 per cent

According to Types of Service

General	86.2 per cent
Nervous and mental	2.4 per cent
Tuberculosis	1.1 per cent
Maternity	1.1 per cent
Industrial	0.9 per cent
Convalescent and rest	0.3 per cent
Isolation	0.5 per cent
Children's	1.2 per cent
Eye, ear, nose and throat	1.5 per cent
Orthopedic	0.3 per cent
Institutional	2.1 per cent
All other hospitals	1.6 per cent

Governmental institutions admitted approximately 30 per cent of all hospital patients, nongovernmental institutions approximately 70 per cent As to types of service, general hospitals received all but about 13 per cent of all hospital patients admitted

Total Patient Days and Average Length of Stay in Hospitals According to Control

	1923	1929	1933	Percent age of Increase 1923 to 1933	Average Length of Stay Days 1931	1933
Federal	12,759,000	16,802,040	20,704,990	62.3	64	63

HOSPITALS ACCORDING TO TYPE OF SERVICE

Separate columns in the accompanying tables are used to show statistics for each of the several types of hospitals, giving the number of hospitals, their capacity in beds and bassinets, the number of patients admitted during the past year, and the average daily census These data are given by states as well as by totals At the bottom of the table are figures for the past seven years for comparison

Percentage of Beds Occupied in Hospitals According to Type of Service

	1920	1930	1931	1932	1933
General	65.5	64.7	64.4	63.3	59.9
Nervous and mental	95.7	94.8	94.6	94.9	95.1
Tuberculosis	82.7	85.5	80.0	85.4	80.0
Maternity	62.8	63.2	58.6	6.6	60.8

Convalescent and rest	70.9	68.3	72.0	67.4	69.2
Isolation	36.1	32.7	33.6	39.0	41.2
Children's	60.9	67.0	69.9	67.8	60.9
Eye, ear, nose and throat	47.7	53.0	52.0	49.9	45.6
Orthopedic	80.2	83.5	78.1	79.4	76.9
Hospital departments of institutions	63.0	65.5	63.9	63.2	60.1
All other hospitals	74.6	78.3	69.2	74.0	79.0
Total hospitals	80.1	79.8	79.6	79.7	78.8

In addition to the three large groups of hospitals known as general, nervous and mental, and tuberculosis, all of which are on the increase, there are a number of types of special hospitals These special

hospitals are usually small and not very numerous. While the volume of their work does not nearly approach that of the large groups mentioned, it is nevertheless of great importance. Over a period of seven years for which reliable statistics have been obtained, an increase is shown in the work of maternity, children's and orthopedic hospitals, and a declining trend in the volume of work in industrial, convalescent and rest, isolation, and eye, ear, nose and throat hospitals.

Births in Hospitals

According to Ownership or Control	
Federal	1,070
State	16,145
County	37,215

City-county	11,913
Total governmental	141,699
Church	21,597
Fraternal	1,622
Industrial	3,175
Individual or partnership	30,120
Independent associations	310,718
Total nongovernmental	567,232
According to Types of Service	
General	649,880
Maternity	50,249
Industrial	3,181
Convalescent and rest	6
Isolation	1
Children's	670
Hospital departments of institutions	272
All other hospitals	8
Total—all hospitals	709,276

Maternity hospitals number 134 as compared with 178 seven years ago. During that time the capacity increased from 5,747 to 7,976 beds, and the average census of patients from 3,695 to 4,857. In the same period, occupancy dropped from 62.8 per cent to 60.8 per cent. During the past three years the number of patients admitted to maternity hospitals has decreased from 91,496 to 82,250, which is obviously a comparatively small decrease, considering conditions in those years. During the past six years in which our census included the number of bassinets, the maternity hospitals have increased their bassinets from 3,621 to 4,660. Since in the same period the general hospitals increased their bassinets from 38,339 to 47,008, there is no apparent indication that the maternity work is shifting either way as between the maternity hospitals and the maternity departments of general hospitals. State hospitals reported 16,145 births during last year and federal hospitals 5,070. Maternity hospitals are credited with about one tenth of the 709,276 births in all hospitals last year.

Orthopedic hospitals as a group are to be credited with a steady but not striking gain, having increased in number from 62 to 69 in the past seven years and in capacity from 5,595 to 6,461, but having decreased in the number of patients admitted from 37,842 to 26,530. No separate data have been obtained for the amount of orthopedic work that is done in general hospitals.

Among the groups of special hospitals showing a rather pronounced slump in volume of work are those operated by industries, which numbered 168 in 1927, 122 in 1932, and 118 in the present survey. The figures in the column for industrial hospitals show a decline in number of beds, number of bassinets, number of patients admitted, and the average census.

Convalescent and rest institutions, which numbered 159 in 1927 with a capacity of 8,143, now number 130, with a capacity of 5,489. Their average census has shrunk from 5,589 to 3,802. The convalescent and rest institutions as a group are not very clearly defined, the designation being used to include institutions properly so named as well as those that accommodate some aged or other chronically ill or mild nervous types and others who are disabled but not acutely ill.

The figures for isolation hospitals show a reduction in number from 98 to 71 since 1927, and in capacity from 8,895 to 6,789. Apparently little change has been made in the number of patients admitted and the average census of those institutions. The type of isolation hospitals rather commonly known to most large towns during the earlier years of the Hospital Register has been replaced by institutions fitted not only for isolation but also for the scientific study of contagious diseases.

Children's hospitals have held their own as to number, capacity and amount of work done since 1927, which might give reason to believe that in normal times they would increase. Their present number of 58 and capacity of 5,486, with admissions totaling 90,307 for 1933, is believed to fall far short of the aggregate of pediatric services in general hospitals.

The hospitalization of patients suffering from diseases of the eye, ear, nose and throat appears to be done largely in the general hospitals, although there are 56 special hospitals in this group, having a capacity of 2,622 beds and an average census of 1,195, whereas in 1927 there were 77 hospitals under this classification with an average census of 1,502 patients.

Each annual census has disclosed that a number of schools, orphanages and special types of homes no longer maintain hospital service for their inmates but send those that are acutely ill or injured to existing hospitals in the same town or community. This accounts for the reduction in number from 530 to 343.

Trends in the Past Decade, 1923-1933

	Hospitals		Beds and Bassinets		Beds		Bassinets		Average Census	
	1923	1933	1923	1933	1923	1933	1923	1933	1923	1933

since 1927. Some of the institutions that do find it advantageous or necessary to maintain a hospital department, such as prisons, have been forced to increase the capacity of those departments so that the 343 now in existence have practically the same capacity as was found in the 530 that were in operation seven years ago—a little in excess of 21,000. The average census of institutional hospitals remains around 12,000, or about the same as that of seven years ago.

While the classification of hospitals that is used in table 2 accommodates nearly all of the 6,437 registered

hospitals and related institutions, there are still 103 hospitals that are of varied and special types not readily classified in the regular scheme. The figures regarding these hospitals are found in the column headed "All Other Hospitals." They include institutions devoted to the care of cancer, cardiac cases, diabetes, chronic diseases, goiter, and drug addiction, as well as a few for venereal treatments only, and some emergency and special surgical services. These institutions had an average census of 6,643 and admitted 114,849 patients during the year.

GENERAL HOSPITALS

In general, the rural communities for local purposes have general hospitals, while urban centers of population favor general hospitals but make it possible to

Analysis of General Hospitals

Federal	23
State	46
County	213
City	222
City-county	40
Total governmental	766
Church	838
Fraternal	2
Individual or partnership	1,091
Independent associations	1,527
Total nongovernmental	3,451
Total general hospitals	4,237

establish special ones. There are 4,237 general hospitals, as compared with 4,322 seven years ago. The decrease in number has been accompanied by a constant increase in capacity, since many general hospitals have been merged with others. The bed capacity, therefore, has increased from 345,364 to 386,713. This year's capacity showed a negligible loss of some 9,000 beds as compared to the capacity for 1932. The bassinets in general hospitals increased from 38,339 to 47,008 in the past six years, showing an increase of 420 bassinets in the past year (between the census of 1932 and that of 1933). General hospitals have now an average census of 231,692, which is 3,608 more than they had in 1927 but 18,803 less than in 1932. The average length of stay in all general hospitals as a group is thirteen days. By reference to table 2 it will be seen that the total patients admitted to general hospitals has declined a little each year since 1931, the first year in which the census revealed the number of patients admitted. Nevertheless, during the year 1933 covered by the last census the general hospitals admitted 6,071,512 patients, or more than 86 per cent of the total of 7,037,982 admitted to all types of hospitals. General hospitals, therefore, admitted 52 times as many patients as all other hospitals combined and 35 times the 170,833 patients entering mental hospitals, the nearest competitor to general hospitals in this particular. The total number of patient days in general hospitals, 84,567,580, is 6,863,095 below the patient days of the preceding year but 1,316,920 above the patient days for 1927. Bed occupancy in general hospitals was 65.5 per cent in 1927 and 59.9 per cent in 1933. General hospitals had 155,021 vacant beds, as an average, in 1933 as against 123,025 in 1927.

WHO OWNS THE GENERAL HOSPITALS?

The federal government operates 235 of the general hospitals, states, 46, counties, 213, cities, 222, and city

and county governments unite in the operation of 40 general hospitals. This makes a total of 756 general hospitals supported by public taxation.

Eight hundred and thirty-eight general hospitals are operated by church groups, 25 by fraternities, 1,091 by individuals and partnerships, and 1,527 by independent hospital corporations, making a total of 3,481 general hospitals that are under nongovernmental or "voluntary" control.

FOR PROFIT AND NOT FOR PROFIT

Those hospitals which are classified as independent associations are maintained by corporations that were formed for the express purpose of conducting the hospitals. They are independent because they are not conducted under the auspices of some other corporation as are church, industrial and governmental hospitals. The independent association hospitals number 2,055. Of these, 232 reported that they are incorporated for profit, 1,113 not for profit, and 710 did not make clear the exact nature of their corporate provision with regard to profit. Adding these 1,113 not for profit to the total number of 984 under church control gives a total of 2,097 hospitals incorporated not for profit, which is at least nine times the 232 that declared themselves incorporated for profit. It may be assumed that practically all of the individually owned and partnership hospitals, although not incorporated, are operated for profit.

TUBERCULOSIS HOSPITALS

Hospitals and sanatoriums for the treatment of tuberculosis seem to remain about stationary so far as the number of institutions designed for that purpose is concerned. There were 508 such hospitals in 1927 and there are 497 now. During that time the rated capacity, however, rose from 63,170 to 70,682, the increase being steady. There were 84,327 individuals admitted as patients during this census, an increase of 3,765 over the census of two years ago. The institutions for the treatment of tuberculosis in the state of New York reported 14,377 patients admitted, Pennsylvania, 6,232, Massachusetts, 5,375, California, 4,714, New Jersey, 4,302, Texas, 4,250, Arizona, 2,870, Colorado, 10,076, and New Mexico, 928. The agencies that maintain hospitals for the treatment of tuberculosis, together with the number of such institutions supported by each agency are as follows:

Federal	22	Church	22
State	62	Fraternal	6
County	18	Industrial	1
City	30	Individual or partnership	49
City-county	14	Independent associations	106
Total governmental	313	Total nongovernmental	184
Total tuberculosis hospitals			497

MENTAL HOSPITALS

Hospitals for mental diseases number 621, a decrease of only 3 from the preceding census. They have a total rated bed capacity of 498,955. This is an increase of 19,407 beds for the year, which represents some slackening in the rate of increase of these institutions due, no doubt, to the business conditions prevailing in these years. Mental hospitals admitted 170,833 patients as compared with 169,851 the preceding year. The average census, however, was 474,787, a sizable increase over 455,473 for the previous census. Some idea regarding the distribution of patients among the several types of nervous and mental institutions may be obtained from the following classification, which tells

what percentage of the total average census of patients was shared by each classification

Veterans Administration hospitals	2.7 per cent
Other federal institutions	1.2 per cent
State hospitals and asylums	67.2 per cent
State schools and colonies	14.8 per cent
Other state institutions	2.3 per cent
County and city institutions	8.3 per cent
Total governmental	96.5 per cent
Private endowed hospitals	0.4 per cent
Private sanatoriums	2.0 per cent
Other private institutions	1.1 per cent
Total nongovernmental	3.5 per cent

While the mental hospitals under government ownership care for 96.5 per cent of the average census of all mental hospitals, the private institutions care for 3.5 per cent. The more complete census reported last year indicated that with respect to total discharges these government institutions were credited with 75.8 per cent and the private institutions with 24.2 per cent.

HOSPITALS IN UNITED STATES POSSESSIONS

That hospitalization is assuming quite considerable proportions in the territorial possessions of the United States is attested by the presence of 215 hospitals in those possessions, 95 of which are in the Philippine Islands, 45 in Hawaii, 41 in Puerto Rico, 18 in Alaska, 10 in the Canal Zone, 5 in the Virgin Islands and 1 in Guam.

Hospitals in United States Possessions

	Hospitals	Patients Admitted	Beds	Base-line	Average Patients	Births
Alaska	18	3,541	518	61	219	2,09
Canal Zone	10	22,156	1,617	39	739	972
Guam	1	3,439	120		106	125
Hawaii	45	38,458	4,702	227	3,411	2,776
Philippine Islands	91	67,392	8,497	424	5,707	7,098
Puerto Rico	41	15,451	2,918	261	1,027	2,416
Virgin Islands	5	1,686	322	24	250	111
Totals	(1933) 215	152,053	18,794	1,036	12,442	13,757
	(1932) 204	119,326	18,335	729	12,872	8,416
	(1931) 202	104,844	17,901	651	12,498	7,148

The prompt response of these hospitals, like that of those on the continent, has contributed appreciably to the completeness of the census. The figures from those reports compiled here do not indicate any considerable expansion in building programs but show for the past two years an increase in number of patients admitted from 104,844 to 152,053. The average census of patients remains stationary, although the number of births in those hospitals for the two years increased from 7,548 to 13,757.

PHYSICIANS CONNECTED WITH HOSPITALS

The physicians whose names were supplied in this census as having hospital connections reached the grand total of 126,261. This is the net figure after the elimination of duplicate names from the list of staff members. Included in this are 2,312 superintendents, 7,970 interns, 2,348 resident physicians and 113,631 members of staffs. The lists of staff members includes those on regular, consulting, associate, courtesy and other types of staff designations. The census for 1932 found 113,730 physicians connected with hospitals, and in 1929 there were 90,903.

DIRECTORS OF PATHOLOGIC AND OF RADIOLOGIC DEPARTMENTS

Presented here for the first time are some arresting data pertaining to clinical laboratory and x-ray facilities. The compilation reveals that 4,324 hospitals supply laboratory service and 4,677 have x-ray departments

out of 6,437 total hospitals, or 67 per cent and 72 per cent, respectively. Beyond interest in actual number of laboratories is concern for competent medical supervision in both departments.

The District of Columbia is represented as having the best record in this regard, since nearly 100 per cent of the hospital laboratories reported in the District are said to be under adequate medical supervision. Nevada has less than one third of the reported laboratories under the direction of trained physicians. All other states say that over one half of the reported laboratories have doctors of medicine as directors.

Directors of Pathologic and of Radiologic Departments in Hospitals Having Those Departments

State	Hospitals Having Clinical Laboratories	Director of Clinical Lab.		Hospitals Having X-Ray Departments	Director of X-Ray Dept.

Generally, the radiologic laboratories are more frequently supervised by specially qualified physicians than are the clinical laboratories.

DENTISTS CONNECTED WITH HOSPITALS

Nine hundred and sixty-eight hospitals reported that they have dentists in attendance. The number of dentists reported as having connections with hospitals is 3,018. There are 82 dental interns and 23 resident dentists.

SCHOOLS OF NURSING

In the list of registered hospitals contained in this issue, those schools of nursing that are accredited by the state board of nurse examiners are marked with a small diamond, those that are recognized for affiliated courses in nursing are marked with a dot in a circle.

Information regarding the schools of nursing was supplied by the hospitals themselves, their standing with the state boards of nurse examiners was attested by the respective boards in all states as of Jan 1 1934

There is a total of 1 760 schools of nursing, of which 1,606 have been reported as state accredited and 154 unaccredited The number of students enrolled was not ascertained in this census but was found to be increasing according to the annual census for 1932 At that time there were 1,934 schools of nursing, of which 1,656 were accredited and 278 unaccredited At that time the student enrolment in all of the 1,934 schools of nursing was 86,649

SUPERINTENDENTS OF HOSPITALS

In 1933, 36 per cent of all hospital executives were physicians, 40 per cent were nurses and 24 per cent were laymen, in 1926, 38 per cent were physicians, 24 per cent were nurses and 37 per cent were laymen There is an apparent tendency for physicians and nurses to occupy these positions As a general rule physicians are found occupying these positions in the larger hospitals, nurses in the smaller hospitals, and

laymen acting as superintendents in the average sized hospitals There are quite a few exceptions to this rule A change of superintendents was made in 538 hospitals last year

OUTPATIENT DEPARTMENTS

The rather complete statistics on the outpatient departments gathered in the annual census of 1927 afford a means of comparison with the still more com-

plete figures resulting from the present survey An opportunity is also afforded to observe the effect of a serious business depression on the attendance at outpatient departments In reading these figures it should be borne in mind that only outpatient departments that are operated by hospitals or those that are closely affiliated are included

Outpatient Departments Comparing 1927 and 1933

Totals	2 130	2 351	6 750 388	9 519 427	10 804 566	32 822 077

The accompanying tables tell the number of outpatient departments, the number of outpatients, and the number of visits made by those patients, during the years 1927 and 1933, respectively While the number of outpatient departments increased in that time from 2,130 to 2,351, or only 10 per cent, the number of patients increased 41 per cent, or from 6,750,388 to 9,519,427 The number of visits by outpatients increased 138 per cent, or from 13,804,566 to 32,822,077 Reference to the accompanying table will show the increase in number of departments, number of patients, and number of visits, both actual and by percentages, for different geographic sections of the country The North Atlantic, South Atlantic and North Central States made the largest showing in the percentage of increase in departments, number of patients and number of visits The South Central and Western states show almost no increase in number of outpatient departments and number of outpatients but an extremely heavy increase in the total number of visits

In respect to the number of departments and volume of work, New York is easily the leader among states,

with its 267 departments, 2,165,711 outpatients and 7,743,191 visits Pennsylvania reported 202 departments but dropped far behind New York in number of patients and visits Other states that reported large numbers of departments were California, 133, Massachusetts, 125, and Illinois, 112

Since the questionnaire that was used in the present census was purposely very brief in order to obtain a high percentage of returns, a definition of outpatient departments was not offered The questions read

* Decrease

expected An analysis of the questionnaires on which outpatient departments were recorded shows that among the 2 351 departments 796 had a thousand patients or less for the entire year, 618 had from one thousand to five thousand 360 had from five thousand to twenty thousand, and 108 had over twenty thousand patients Four hundred and sixty-nine hospitals did not tell how many patients they had

While there has without doubt been a considerable increase in the work of outpatient departments during the last seven years the present volume of 32,822,077 visits is not so astonishing when one compares it with the inpatient departments, in which the total of the patient days was 295 748,915

Some outpatient departments have been opened up during the depression to enable the staff to keep in closer touch with financially affected patients who might otherwise go to free clinics On the other hand, some hospitals have closed their outpatient departments in order to cut down expenses

siderable investigation is carried out in the case of each hospital before it is admitted to the Register

First, hospitals supply information regarding their capacity, equipment, classification and list of staff Each member of the staff is then looked up in the bio-

graphic files of the Association Information and advice are obtained from the secretaries and other members of the county medical societies, from state, city or county health departments, from the councilors

of the state medical associations for the district in which the hospital is located, and from other sources. Investigation of hospitals for internship and residency approval is more comprehensive than for registration.

A personal visit by a member of our staff of hospital examiners is made to each hospital approved, or applying for approval, for internships or for residencies. An increasing number of other hospitals are being inspected.

MATTERS OF INTEREST TO HOSPITALS TRAINING RESIDENTS OR INTERNS

Since the appearance of the last Hospital Number of *THE JOURNAL*, a few changes in methods have occurred affecting residency and internship approval which are of interest to hospitals. These new methods are designed to achieve more accurate registration of credit for internships and residencies served, or other desired results.

RESIDENCY APPROVAL

The most conspicuous changes in the past year have occurred in the field of residency training. Certification of specialists occupies, at present, a position of considerable importance in the eyes of the entire medical profession. The part that hospitals now play in the training of specialists is fully acknowledged. Many institutions offer extremely advantageous opportunities to physicians who expect to enter a limited field of practice.

It is not the Council's intention to emphasize unduly or to stimulate the production of specialists. It has been felt however, that periods of residency will be acceptable to special examining boards only as they fulfil certain basic requirements. It was to satisfy this obvious need, then, that revised regulations for the government of residency services in hospitals were adopted. The new "Essentials" will be sent on request.

The biographic file maintained by the American Medical Association covers every physician in the United States and is designed to provide a verified statement of his entire medical education, including internships and residencies. It will, if necessary, include records of other postgraduate work that may affect the qualifications of physicians in special fields. This body of information cannot be duplicated elsewhere, and it is reasonable to assume that examining boards may need to refer to it rather frequently for verification of submitted data.

Proper and accurate recording of the service of residents is of considerable importance and involves reporting the required information by all approved hospitals each year. It will be the practice, then, to receive annual statements from all institutions approved by the Council, as a basis for continued approval of residencies and as a means of keeping biographic data up to date. Internship hospitals have submitted statements of this nature for the past half dozen years.

INDIVIDUAL INVESTIGATIONS OF RESIDENCIES

Whereas formerly an institution was granted blanket approval of all residencies it might undertake to offer, now approval is extended only to individual residencies that have undergone individual scrutiny. Investigation of these positions is going on at the present time, by the annual report method for residencies previously approved, by application blanks for residencies wishing to be approved and by visits to hospitals by the Council's staff of hospital inspectors.

HOSPITALS REFUSED REGISTRATION

There are 576 institutions which, because of alleged unethical or questionable practices, admission to their staffs of members who are seriously unqualified, either morally or professionally, flagrant methods of advertising or for other valid reasons, are deemed unworthy of being included in any published list of reputable hospitals. The 576 unregistered institutions have only 16,685 beds, or 16 per cent of all hospital beds.

Application blanks for residency approval are carefully examined to determine the degree of compliance with the present regulations. In most instances, a personal visit by one of the staff precedes approval.

RESIDENCES IN PSYCHIATRIC AND TUBERCULOSIS HOSPITALS

The Council, in revising its residency regulations, realized that special hospitals, particularly psychiatric and tuberculosis institutions, provide excellent opportunities for special medical training, and that employment of personnel is on a different basis than residency appointments in general hospitals. The provision was made, in consequence, that the first three years of employment in a special hospital would be considered as a period of training and would qualify for the approval of the Council as a residency.

MIXED RESIDENCIES

At a recent meeting of the Council, it was decided that recognition may be extended to a classification known as "mixed residencies." This type of experience is expected to provide additional training for men who expect to go into general practice, as well as a broader basis for those who will limit their practice later on. A hospital desiring approval for mixed residencies must comply in all respects with the basic regulations for all residencies.

INTERNSHIP APPROVAL

There have been no concrete revisions in rulings of the Council in respect to internships alone. A number of trends have developed which have served to indicate that the character of intern training is changing. Consideration of these changes customarily takes place in the Educational Number of *THE JOURNAL*.

CHANGES IN METHOD OF LISTING APPROVED HOSPITALS

In the last Educational Number of *THE JOURNAL*, hospitals approved for residencies were grouped according to specialties. This represented a considerable advance in convenience at some sacrifice of information contained in former lists.

The Council has felt that additional information could well be given in its list of approved internship hospitals. It was thought that the intern, in consulting this list, should obtain some knowledge as to the proportion to total admissions which charity patients hold. This, of course, is in consideration of the advantages in teaching which interns obtain from this group of patients. It was also the general opinion that the list should indicate whether the internship is of the straight, mixed or full rotating type. Suitable data are now being received from all approved hospitals which will make such additions possible.

WHEN WITHDRAWAL OF COUNCIL APPROVAL BECOMES NECESSARY

There is often some misunderstanding or lack of information about the reasons for withdrawing Council approval of residencies or internships. These reasons may be set down here in order of frequency, with explanatory notations.

1 Approval is withdrawn, naturally, when a hospital abandons its teaching program. It is also withdrawn when a hospital for any reason, does not make its internships or residencies continuously available to applicants. This policy is necessary in order to keep the lists of approved hospitals accurate and to avoid many useless applications by eligible candidates. The Council, in reality, is approving opportunities for training, governed by certain established regulations and if these are not complied with, extension of approval is misleading and misdirected.

2 Approval is withdrawn when hospitals employ in any capacity irregular or cult practitioners, or use graduates of unrecognized medical schools as interns or residents. The reasons for this step are quite obvious. Most violations in this class are matters of carelessness on the part of administrators or intern committee. The Council has supplied all approved hospitals on several occasions with lists of approved medical colleges and there is now no plausible excuse for inadvertent selection of unqualified interns.

3 Notable departures from the established rulings governing the actual teaching of house officers result

in withdrawal of approval. Hospitals find most difficulty in observing the 15 per cent necropsy requirement, the presentation of clinical pathologic conferences, and the provision of suitable library facilities for the house staff.

REVISION IN COMPUTATION OF NECROPSIES

In view of handicaps under which certain metropolitan hospitals labor, a change was made in the Council's method of necropsy computation. All bodies removed from hospitals by coroners or medical examiners and, in consequence not available for necropsy performance in the presence of the interns, are not to be counted either as deaths or as necropsies. This will include all bodies removed from hospitals and directed to medical schools for dissection.

It will be remembered that the Council has disregarded stillbirths, either as deaths or as necropsies, in these computations. All other deaths and all other necropsies should be counted.

LIST OF GRADUATES FROM FOREIGN MEDICAL SCHOOLS AS INTERNS

Frequent inquiry is made as to the Council's attitude with respect to employment of foreign medical graduates as interns in approved hospitals. The Council is not in a position to endorse the educational qualifications of graduates of any foreign medical schools. It therefore recommends that graduates of approved medical schools in the United States and Canada should receive first choice in the selection of interns.

ESSENTIALS OF A REGISTERED HOSPITAL

Prepared by the Council on Medical Education and Hospitals of the American Medical Association

General Statement—The American Medical Association gives recognition to hospitals by admitting to the Hospital Register those that are found to qualify according to the essentials contained in the following paragraphs.

Registration is a basic distinction between all recognized hospitals and those that are refused recognition. It is a prerequisite to the consideration of a hospital for approval for interns or for residencies in specialties.

The registration of hospitals, the approval of hospitals for interns, approval for residencies in specialties, and all other service of the Association regarding hospitals is carried on by the Council on Medical Education and Hospitals.

It is the desire of the Council to cooperate in every way for the improvement of hospital service, whereby the sick and injured may be provided with scientific and ethical medical care.

The Council does not have nor does it assume legal authority over any hospital. It recognizes clearly that the officers in charge of such institutions have the unquestioned right to conduct the hospitals in any way they may deem wise. If a hospital desires to have its name appear on the American Medical Association Hospital Register and thus have the endorsement of that Association it should be willing to comply with the principles which the Council on Medical Education and Hospitals considers necessary.

Essentials of a Registered Hospital—Hospitals seeking admission to the register should have the following qualifications:

1 *Organization*—The organization should consist of a board of trustees or other supreme governing body having final authority and responsibility and an executive officer or superintendent to carry out the policies adopted by the governing body. The executive officer should be assisted by adequate competent personnel.

Regardless of the form of organization the hospital should function primarily in the interests of the sick and injured of the community.

2 *Staff*—This constitutes the most important essential. The staff should be organized and composed of regular physicians who are properly qualified as to training, licensure and ethical standing.

Staff membership and the use of the hospital's facilities must be limited to doctors in medicine. Where cult practitioners, osteopaths, chiropractors or other healers outside the scope of regular medicine are allowed to use the hospital's diagnostic facilities, to prescribe for or treat patients in the hospital, or to enter orders or other data on the case records, such a hospital obviously cannot be recognized or endorsed by the American Medical Association.

Regular staff conferences should be held at least monthly and preferably more often. All deaths that occur during the period intervening between meetings, perplexing cases, and patients who do not respond to treatment should be discussed. When postmortem examinations have been performed there should be a presentation of the clinical aspect of the patient and the postmortem observations. Interesting pathological specimens from surgery or removed at postmortem should be presented and discussed with regard to the preoperative or antemortem findings.

Minutes of staff conferences should be kept and filed with the hospital records. The activity of the staff as to scientific meetings and clinical and pathologic conferences is an index to the scientific mindedness and progressiveness of the group.

3 *Nurses*—A competent nursing staff should be provided by employing an adequate number of registered nurses who are graduates of schools of nursing recognized by the state board of nurse examiners or by maintaining such a school.

All nursing should be supervised by qualified registered graduates.

4 *Records*—An adequate record system should be maintained. No particular system or set of forms is recommended, since requirements are not the same under varying circumstances. The average case record should include at least a brief medical

history, physical examination, laboratory reports diagnosis operative record, progress notes, nurses' notes and summary. Case records should be complete in every department and reviewed and signed by the attending physicians before they are placed in the permanent file. Roentgenologic interpretations, pathologic descriptions and diagnoses of tissues removed in the operating room, and (when in autopsy) has been performed) a description of postmortem observations, should be included with the patient's record.

Case histories and physical examinations should be recorded in the patient's chart within twenty-four hours after the patient has been admitted to the hospital. A patient should not be operated on, except in the case of emergency, when the history, physical examination and routine laboratory work have not been completely recorded in the chart. The duty of recording these data falls on the attending physician and he should be held directly responsible for the case records.

Monthly and annual analyses of hospital service should be made in order that the staff may be in a position to improve its service.

5 Pharmacy—The handling of drugs should be adequately supervised and should comply with state laws.

6 Pathology—All tissues removed in the operating room should be examined, described and diagnosed by a competent pathologist excepting tissues, such as tonsils and teeth, in which the pathologic changes are quite obvious.

A physician-pathologist should be employed on a full time or part time basis. When this is not practicable arrangements

should be made with a consulting pathologist for tissue diagnosis, postmortem work and the interpretation of the more complicated tests and determinations in clinical and surgical pathology, as well as in general clinical laboratory work. The pathologist preferably should be one listed by the Council on Medical Education and Hospitals of the American Medical Association. The Council's list of physicians specializing in clinical pathology or pathology is available on application.

Autopsies—Every effort should be made to secure consent for autopsies, which should be performed by a pathologist or the best qualified other physician available.

7 Radiology—The hospital should provide or have ready access to radiologic equipment and service. When a full time or part time physician-roentgenologist cannot be employed, the services of such a consultant should be secured. Radiologic interpretations must be made only by a competent roentgenologist. A description of the roentgenologic examinations should be placed in the patient's chart. The physician-roentgenologist preferably should be one listed by the Council on Medical Education and Hospitals of the American Medical Association.

A list of physicians specializing in radiology and roentgenology is available on application.

8 Ethics—In order that a hospital may be eligible for registration it will, of course, be expected that the staff and management conform to the principles of medical ethics of the American Medical Association with regard to advertising, commissions division of fees secret remedies, extravagant claims, over-commercialization and in all other respects.

ESSENTIALS IN A HOSPITAL APPROVED FOR INTERNS

Prepared by the Council on Medical Education and Hospitals of the American Medical Association

I Hospitals Eligible for Approval

Only general hospitals are eligible which have at least 100 beds with a minimum daily average of 75 patients, and which provide a variety of medical, surgical, obstetrical and pediatric patients either in the hospital proper or through suitable affiliations with other institutions.

II The Hospital Staff

1 CHARACTER OF STAFF—There must be an organized staff of ethical physicians who hold the degree of doctor of medicine from acceptable medical schools, who are of unquestioned professional and moral integrity, who are proficient in general practice or in the special fields to which they devote themselves, who give personal attention to the patients under their charge and who will provide adequate facilities, instruction and that sympathetic cooperation without which interns and graduate students cannot obtain the practical training for which they are serving the hospital.

2 GRADUATES IN MEDICINE—The hospital must not only confine membership on its staff to reputable practitioners who have received the degree of doctor of medicine from medical schools considered acceptable by the Council on Medical Education and Hospitals of the American Medical Association, but also must apply this ruling to every person permitted to treat or prescribe for the sick in the hospital or in any of its departments. The ruling does not apply to the treatment of patients by nurses, masseurs, and other like assistants when acting under the orders of any physician on the attending staff.

3 STAFF CONFERENCES—The hospital staff shall conduct a regular monthly staff conference at which the work of the various hospital departments is considered and where interesting hospital cases and selected autopsy reports may be presented for general discussion. The interns should be expected to attend these meetings and take an active part.

III Laboratory

1 EQUIPMENT—There must be a clinical laboratory in the hospital equipped for the ordinary routine tests, and for the more technical bacteriologic, serologic, chemical, basal metabolic,

and tissue examinations. A competent physician-pathologist must be in charge of the laboratory, who shall supervise the work in general and personally examine all tissues from the operating rooms and furnish reports of gross or microscopic findings as indicated. Records must be kept in the laboratory of all work carried out by the department, and copies should be filed with the patient's clinical record.

2 AUTOPSIES—Inasmuch as the percent of autopsies has come to be recognized as an index of the educational activities in a hospital, no institution will be approved for the training of interns which does not have a record of autopsies of at least 15 per cent. The autopsies preferably should be performed in the hospital by or under the supervision of the hospital pathologist who has special knowledge of this type of work and who can furnish reports that include a summary of the clinical record and a detailed description of gross and microscopic findings.

3 AUTOPSY ROOM—The hospital must provide an autopsy room where postmortem examinations can be held in the presence of staff members and interns.

IV Department of Radiology

This department must be equipped for at least roentgenographic and roentgenoscopic procedures and must be directed by a physician-roentgenologist who is properly qualified for the work which the department purports to do. Records of the work carried out must be on file in the department, and copies should be filed with the clinical charts.

V Medical Library

There must be a working medical library, in charge of a librarian, which should contain a useful selection of late editions of standard text and reference books and current files of not less than ten of the better medical journals. The library should be inside the hospital building and be located where it is readily accessible to the interns and staff members. Collections of choice reference books in pathology and clinical diagnosis and in roentgen-ray work should be found respectively in the pathologic and roentgenologic departments.

VI Histories

1 COMPLETE HISTORIES—There must be complete histories, giving the patient's complaint, physical examination at time of admission to the hospital, preliminary diagnosis, laboratory

findings, description of operation, if any, progress notes, final diagnosis, condition on discharge and, in case of death, autopsy findings if secured

2 ENDORSEMENT OF HISTORIES—The histories should show by signatures or initials all persons writing them or parts thereof, as well as the staff members by whom the histories are verified. Likewise, all orders and progress notes should be initialed or signed

3 RECORDS—A competent clerk should have charge of the records pertaining to patients. To be of educational value the records must be so handled as to be readily accessible when desired for special study or reference work. There should be an alphabetical index of patients with cross files according to diagnoses, operations, etc. Lists should also be kept of patients according to departments, i. e., medical, surgical, obstetrical, pediatric, genito-urinary, gynecological, eye, ear, nose and throat, tuberculosis, etc., and of hospital days or daily average of patients, deaths and autopsies (under 48 hours and over 48 hours). Histories should be filed so as to be easily accessible. Complete monthly reports and annual summaries should be prepared covering the various hospital departments

VII Interns

1 PURPOSE OF INTERNSHIP—It is emphasized that the object of the general internship is to round out the medical graduate's training so as to enable him to enter into the general practice of medicine and not to equip him to enter directly on any specialty. For the latter he should obtain further and different instruction

2 INTERN SCHEDULE—The intern service should cover at least twelve months and should be so arranged as to furnish the interns adequate instruction in medicine, pediatrics, obstetrics, surgery and in the laboratory and x-ray departments. The interns should be selected from medical colleges rated in class A by the Council on Medical Education and Hospitals

3 WORK OF THE INTERNS

(a) *Histories*—The interns should personally record a history, a physical examination and their own diagnosis on private and ward patients on their service. The attending physician should in each instance check the intern's work, call attention to errors and supplement the clinical records with any additional findings. The interns in following the progress of the patient should enter progress notes on the chart and the patient's condition on discharge. When a hospital has a shortage of interns a provision should be made whereby the interns on duty may not be burdened by an unreasonable amount of history writing. In such instances it is recommended that a definite number of cases be assigned to the intern and that the other charts be completed by the attending physicians

It is especially emphasized that surgical charts should be completed promptly and except in emergencies before the patient is taken to the operating room. Unless this is done the educational value of the intern's work is considerably lessened

(b) *Medical Department*—This department should afford the interns an adequate amount of instruction in general medicine and pediatrics. Preferably there should also be facilities for the study of tuberculous, neuropsychiatric and contagious patients. In connection with the work in this department it is recommended that the interns be instructed in the feeding of both infants and adults as required in various diseases, and that they obtain a reasonable amount of technical experience under a trained dietitian

(c) *Obstetrical Department*—The intern should obtain practical experience in this department by personally delivering at least ten patients while on the service. He should assist at all other deliveries and not act as anesthetist for maternity patients while assigned to this department

(d) *Surgical Department*—It should be impressed upon the interns that it is more important for them to acquire skill in diagnosis and postoperative treatment than to learn technical operative procedures. However, in order that the interns may follow their cases closely they should be permitted to act as first assistant in the operating room whenever possible. To stimulate further interest on the part of the interns, it is also advisable, when an opportunity presents itself, to permit them

to perform surgical procedures under constant supervision. Surgical dressings should be assigned to the intern so that he may observe carefully the postoperative course

The intern should obtain instruction and experience in the administration of the various kinds of anesthetics under the supervision of experienced anesthetists

(e) *Laboratory Department*—The intern should have a definite laboratory course wherein he renews his acquaintance with routine examinations and gains instruction from the pathologist regarding the more technical procedures and tissue diagnoses. Interns in the hospital should be present and assist at autopsy procedures when possible, and should receive instruction in technique and in interpretation of findings. Every effort should be made that other assignments may not interfere with the interns' attendance

(f) *X-Ray Department*—The roentgenologist should instruct the interns by lectures and demonstrations in the technical, diagnostic and therapeutic use of x-rays

(g) *Outpatient Department*—When facilities are available in the outpatient department a regular service should be instituted for the interns if practicable, or else the work in this department should be carried out in conjunction with the respective services in the hospital

4 INSTRUCTION OF INTERNS—All attending physicians should allow sufficient time at rounds to check the interns' work and to instruct them in connection with their patients. Special attention should be given at this time to dangerously ill patients, and the advice of other physicians on the staff should also be sought

At least a weekly period should be arranged for conducting clinical-pathological conferences, x-ray lectures or other special lectures or clinics for the interns

The interns should be encouraged to read medical literature in connection with their patients and should preferably be assigned articles in the medical journals for special study and report

5 RECORDS OF INTERNS' WORK—State medical examining boards, medical schools and other agencies often desire detailed information regarding the interns' training and, therefore, each hospital should keep a weekly or monthly record of each intern's work. This information is most conveniently supplied to the superintendent or record office by the interns themselves on special forms where space is provided for the following: period covered, service, number of patients admitted on service, number of histories and physical examinations, number of anesthetics given, number of operations assisted at, number performed, number of deliveries attended, number performed, autopsies attended, hours in laboratory, lectures attended, clinics attended, etc.

6 RULES REGARDING INTERNS—The hospital should have a set of printed or written rules and regulations defining the rights, duties and privileges of the interns, a copy of which should be furnished to each intern

7 INTERNS' LIVING QUARTERS—The hospital shall provide reasonably comfortable living quarters for the interns with opportunities for recreation, both indoor and outdoor, appropriate to the locality and environment of the hospital

8 FAITHFUL SERVICE FROM INTERN EXPECTED—For all the privileges granted the intern it is understood that the hospital has the right to expect faithful service in return

The breaking of contracts by interns will be recorded against their standing in the files of the American Medical Association's office unless the interns can show just cause for such action.

VIII Admission to the Approved List

1 APPLICATION FOR APPROVAL—Hospitals that want to be accredited for intern training should apply to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago

2 APPLICATION FOR APPROVAL OF INTERNSHIPS—Application blanks in duplicate will be supplied on request. These should be filled out carefully by the superintendent or by some staff member who is acquainted with the intern service in the hospital, and one copy returned to the office of the Council

HOSPITALS REGISTERED BY THE AMERICAN MEDICAL ASSOCIATION

The following list contains the names of 6,437 hospitals, sanatoriums and related institutions that are located in the United States and 215 in the insular possessions. It omits the names of 576 hospitals which, after investigation, were not accepted. The inclusion of the name of any institution may be taken as an indication that evidence concerning irregular or unsafe practices in that institution has not come to the attention of the Council on Medical Education and Hospitals. The list in each state is given in two sections: (1) hospitals and sanatoriums and (2) related institutions. The related institutions include some general hospitals lacking certain essentials, nursing homes, school infirmaries, prison infirmaries, custodial and other institutions designed to give some medical, nursing or convalescent care in an ethical and acceptable manner, but not strictly hospitals. In the statistics the two classifications are consolidated.

KEY TO SYMBOLS AND ABBREVIATIONS

- * Approved for general internship the fifth year in medicine, by the Council on Medical Education and Hospitals
- + Approved for certain residences in specialties for graduates in medicine who have already had a general internship or its equivalent in private practice

- ◊ School of nursing accredited by state board of nurse examiners
- Affiliated for nurse training on state accredited basis

The column headed "Type of Service" tells what diseases or conditions are treated in each institution, as follows:

Ca	Cancer	ENT	Eye, ear, nose and throat	Inst	Institutional	Orth	Orthopedic
Card	Cardiac	Gen	General	Mat	Maternity	SKCa	Skin and cancer
Child	Children	GTB	General and tuberculosis	MatCh	Maternity and children	TB	Tuberculosis

SATURDAY, MARCH 31, 1934

HOSPITALS IN 1933

The total patient days in all hospitals in the United States in 1933 was approximately 296 million. There were 173 million patient days in mental hospitals, 85 million in general hospitals, 22 million in tuberculosis sanatoriums and around 16 million in other special hospitals. The popularity of the use of hospitals in childbirth is attested by 709,276 births in hospitals last year. One tenth of these were in maternity hospitals. Outpatient departments served nearly 14 million persons, who made close to 33 million calls at these departments. These figures attest the vastness of growth in this phase of medical practice.

The fact that 2,878 hospitals have their clinical laboratories directed by pathologists or, at least by physicians establishes a figure from which to measure future progress. The remaining 1,089 hospitals that have laboratories failed to report regarding their medical supervision. Radiologists or other physicians are reported in charge of 3,487 roentgen-ray departments while 892 departments reported lay directors or failed to specify.

Further evidence of the growing extent of medical practice in hospitals is contained in the names of 126,261 physicians having hospital connection, duplicates eliminated. Of these, 113,631 are on regular, consulting and other staff lists, 2,312 are physician superintendents, 2,348 are resident physicians and 7,970 are interns. The number would seem to represent well nigh all the qualified physicians in active practice. There are, however, still problems of local distribution, both as to physicians and as to hospitals.

The list published on pages 1021 to 1083 in this issue contains the names of 6,437 registered hospitals together with the capacity, the ownership or control, the type of service rendered, location and other important data. The total capacity of all hospitals is 1,027,046 beds and 52,464 bassinets. There are 576 institutions which, after investigation, were refused registration. The total capacity of those refused, however, is only 1.6 per cent of the capacity of all hospitals.

Special symbols show 677 hospitals approved for internships, 370 for residencies in specialties and 1,760 operating state accredited schools of nursing. The special recognition given to hospitals, as well as their registration and classification, is based on inspection wherever possible. Several hundred additional hospitals are visited each year. However, whether a hospital is inspected or not, reports are obtained from superintendents, intern committees, and others who are in best position to know conditions.

The privately supported hospitals and in the main private general hospitals have been most hard hit by the depression. General hospitals, most of which are wholly or partially dependent on pay or part-pay patients, have not participated in the increase of thirty million patient days for 1933 over those of 1929. That increase went to the mental hospitals, most of which are supported by state governments. Furthermore, the general hospitals of the country carried a burden of idle beds, averaging 155,000, equal to the number of general hospital patients in the entire United States west of Pittsburgh. The resulting loss of revenue, plus the actual cost of maintaining these idle beds, is sufficient to place nearly all such hospitals in a precarious financial condition.

Still another drop in the revenue of general and some other hospitals has been due to the reduction in the length of time that patients have spent in hospitals. The average length of stay in all general hospitals in 1933 was fourteen days. That of many individual institutions ran as low as six or eight days. Such a record, although excellent for the reputation of the institution, is not so favorable to its finances.

Private hospitals have seen a considerable proportion of their paying patronage reduced to such financial straits as to be forced to enter the tax-supported institutions. At the same time the amount of charity work, non-pay hospitalization and delinquency in payments have materially increased.

This condition has forced hospitals to invent new ways of carrying on their struggle for existence. There may be some compensation and consolation for hospitals in that their experiences during these years have resulted in some improvement of methods and in the discovery of economies, some of which might well be adopted permanently. There is room for every consideration and all possible support that can be given to deserving hospitals by the medical profession as well as by the public.

It would seem that the nation as a whole is oversupplied with general hospitals and other types of institutions excepting those for mental diseases and tuberculosis. These two types of institutions, especially many of the large state mental hospitals, are indeed crowded. With regard to other than mental and tuberculosis hospitals however, there are, in some places, large and costly investments in idle beds. The question of overbuilding is one that in the last analysis is the

special problem of each individual community. Therefore, in the contemplation of additional hospital facilities, the community should study carefully (1) the adequacy of existing hospital facilities and (2) future needs. Competitive building will hinder rather than help. A hospital building project to sell real estate or to expand the sale of equipment should be deprecated. Plans for the future should be based on reasonably expected growth, not on the present abnormal situation and certainly not adopted as a financial promotion primarily.

CERTIFICATION OF SPECIALISTS

At the last annual session of the American Medical Association a resolution was adopted authorizing the Council on Medical Education and Hospitals to express its approval of such special examining boards as conform to standards of administration formulated by the Council and urging the Board of Trustees to use the machinery of the American Medical Association, including the publication of the Directory, in furthering the work of such examining boards as may be accredited by the Council. Pursuant to that action, the Council is beginning with its task of designating and classifying the specialists of the United States. Arrangements have been made in the publication of the next edition of the American Medical Directory to indicate those physicians who hold the certificates of some of the boards already established, and also to describe the nature of the boards which will be considered acceptable by the Council. Already certifying boards have been established in the fields of ophthalmology, otolaryngology, dermatology, and gynecology and obstetrics and boards are said to be forming in the fields of roentgenology and orthopedic surgery. Moreover, there is some evidence of a desire to establish a special board in the field of general surgery, a board in which the section of the American Medical Association and representatives of the leading surgical associations should have a part.

In the meantime, as a result no doubt of suggestions made at a hearing before the reference committee of the House of Delegates at the meeting in Milwaukee the certifying boards already established have organized among themselves an advisory board which it is presumed, will serve to coordinate the activities of the several boards, standardizing their methods of work and advising with them in their operation. The functions of this coordinating board are clearly to aid in the practical operation of the boards rather than to define their methods of work or to sit in judgment on the results of their operations. That clearly according to the resolution adopted by the House of Delegates of the American Medical Association, is to be the function of the Council on Medical Education and Hospitals. As an independent body the purpose of which will be to maintain the operation of the certifying boards in the specialties at a high level both as to standards

adopted and as to conduct the Council on Medical Education and Hospitals could hold no representation on this coordinating board. It may, of course, advise with the coordinating board at such times as its advice may be sought. It would hardly be in order for a body sitting in judgment to hold membership on a board whose work it was expected to judge.

The machinery of the American Medical Association in support of the work of the certifying boards has already begun to function to some extent. The mere description of the boards in the American Medical Directory and the listing of those who hold the certificates is in itself a vital step in making effective the advancement of the specialties concerned. Beyond this, however, the American Medical Association has broadcast over the radio, through newspapers and to some extent through its periodical *Hygeia* a description of the certifying boards and a statement as to the significance of their certificates. As information concerning the work of these boards becomes more widely disseminated among both the medical profession and the public, their prestige must grow. Eventually the young man who wishes to make for himself a place in any of these specialties will consider the securing of a certificate by a council-recognized certifying board as the first step in such a procedure. Hospitals will also do well to be guided in their staff appointments by similar qualifications.

Movements of this type necessarily develop and advance slowly. However, with the qualifications and restrictions that have been outlined, there is reason to believe that the certifying boards will do much to advance the quality of specialistic service available to the people and to the profession of our country.

RESPONSE OF THE COLON TO CATHARTICS

Probably no part of the physiology of the body impresses itself more persistently on the consciousness than activity of the large intestine. Whether the contents collect and remain too long or whether the organ is prone to empty too rapidly, the individual is aware of the situation. Consequently, this organ is the object of the greatest amount of self medication. And although various other functions have been demonstrated, the activity of the large intestine in absorbing water from its contents and propelling the feces thus formed toward the anus still seems to be its characteristic if not its most important purpose. In an effort to elucidate certain of the details of the action of cathartics on the colon, Larson and Borgen¹ of the Mayo Clinic recently examined the question of the production of mucus and its response to certain drugs under experimental conditions (isolated loop of colon). The function of the mucus secreted seems to be to lubricate the fecal mass, the amount is fairly constant

¹ Larson, L. M. and Borgen, J. A. Action of Cathartics on Isolated Dog's Colon. Arch. Surg. 27: 1120, 1130 (Dec.) 1933.

and tends to be less the quieter the animal. Ten or fifteen minutes after defecation there was an increase, which lasts for about an hour. In pregnancy the amount of colonic secretion is higher than before, and the response to defecation, whether normal or after catharsis, is augmented. Diarrhea of unknown cause was accompanied by an elevated secretion of mucus.

When cathartics were given there was no increase in the production of the secretion of the colonic loop until defecation occurred. With phenolphthalein, senna and rhubarb there was a marked rise in mucus production and a rapid fall to the control level. Although the obvious effects produced by castor oil were no different than those brought about by the foregoing cathartics the secretion into the loop continued at an elevated rate for about four hours. Colocynth induced a prompt and marked rise in secretion and an immediate fall. In contrast to these observations, the results after administration of the saline cathartics and after an enema of water were little different than in the control experiments. The Rochester investigators do not believe that the increase in intra-abdominal pressure incident to defecation serves to force out mucus already secreted in the colonic loop. Close observation of an area of exteriorized mucosa showed an actual increase in the mucus production at the time of defecation. Furthermore, when the act of defecation was interrupted, the production of secretion was only slightly above the control level. It appears that the muscles of the wall of the large intestine are involved in a nervous reflex, thereby contracting and "resulting secondarily in stimulation of secretion of its goblet cells."

A correlated study of the motor activity of the large intestine after the administration of cathartics was carried out on the isolated loop by the balloon method. At rest there were demonstrated continued rapid contractions in the cecal portion of the isolated loop, whereas the distal part was usually quiescent. Respiration had little effect on the movement in the cecum. During normal defecation, the movements of the loop were unchanged until straining occurred, then movement in the cecal portion largely ceased for a time and a wave of contraction passed over the distal segment and activity in this part lasted from fifteen to twenty minutes. With the saline cathartics the motor response was not unusual, the persistence of activity in the distal colon was greater with phenolphthalein and rhubarb, movement lasted still longer after defecation when mild mercurous chloride and senna were administered, and following castor oil it was many hours before the distal segment of the colonic loop was normally quiescent. In general it was observed that, after the use of cathartics, the movements of the isolated loop were of a peristaltic nature.

These observations are in general agreement with those of Raiford and Mulinos² on a section of exteri-

orized colon. By suitable means changes in transverse as well as in longitudinal dimension were recorded. A stimulation of the mucosa causes the longitudinal muscles to contract below the stimulus, enlarging the lumen of the intestine, no contraction occurs above the stimulus. But the circular muscles contract above the stimulus narrowing the lumen and forcing the bolus into the enlarged portion. The repetition of a series of such reflexes gives the appearance of peristalsis. In general, it appears that the so-called myenteric reflex still is an important if not the chief factor in moving the contents of the large intestine in a posterior direction.

Current Comment

ARTIFICIALLY INDUCED LEUKEMIA

In an extensive investigation particularly of susceptibility to cancer, to which reference was recently made in these columns,¹ a study was made of the results of the continued administration to mice of indole, the indirect tumefacient effects of which had been already established by a number of other workers. This study, by Bungeler² in the laboratory of Fischer-Wasels, indicates that with this substance metabolic changes occur similar to those observed after prolonged administration of arsenic or application of coal tar—a shift of metabolism from the normally oxidative type to the fermentative type identified by Warburg with tumor metabolism. A by-product of this work is of special interest. The original repeated administration of indole in rather large doses caused in the mice a high proportion of deaths from general intoxication, while in others it produced a hemolytic anemia with leukopenia and hemorrhage and necrosis in the bone marrow. The dosage, in smaller amount was continued, and animals so treated showed atrophy of the medullary blood-forming centers. Continuation with still smaller doses led to the appearance of regenerative changes in the hematopoietic organs, accompanied by increase of the white cells in the circulation. The anemia however, developed progressively. After eight months of indole administration several animals showed an aleukemic lymphadenosis, several the more usual type of lymphadenosis, one a typical lymphsarcoma, several typical myeloid leukemia and a number aleukemic myelosis. In all, 17.5 per cent of the surviving animals showed what Bungeler regards as apparently neoplastic changes of the blood-forming organs. Of the remaining animals a great majority showed regenerative changes in these organs, with in part the appearance of extramedullary centers of hematopoiesis. A smaller portion showed marked degenerative changes—fibrosis and amyloid degeneration of the marrow, spleen and liver. That these conditions are not of spontaneous origin is indicated by the fact that all intermediate changes were observed between the regenerative and the apparently

¹ The Origin of Cancer, editorial J. A. M. A. 102:214 (Jan. 20) 1934.

² Raiford, T. S. and Mulinos, M. G. Proc. Soc. Exper. Biol. & Med. 31:346, 1933.

² Bungeler, Walter. Die experimentelle Erzeugung von Leukämie, aleukämischen Myelosen, Lymphadenosen und Lymphosarkom. Klin. Wochenschr. 11:1982 (Nov. 26) 1932.

neoplastic lesions. Also, with sufficiently continued indole intoxication, all the animals showed changes of some type in the hematopoietic system. In a large stock of white mice observed over the same period, but used in other experiments, spontaneous lymphadenosis was seen only twice. That such disease is not common in mice is indicated by statistics from Maud Slye's laboratory, which show that its total natural incidence in 15,000 mice was 1.4 per cent. The development of these lesions in animals under conditions known definitely to predispose to tumor development, and the additional fact that organs infiltrated with myeloid or lymphocytic elements showed the metabolic change to aerobic fermentation characteristic of malignant tumors, would seem to place this group of hematopoietic diseases decisively in the category of neoplasms—a grouping that has long been suspected. The fact that a diversity of changes was observed serves also to clear up at least in part a feature of embarrassment in the classification of these diseases, in which cases of atypical or intermediate character have clouded a conception already sufficiently complicated.

Medical Economics

ANOTHER COLLECTION COMPANY EXPLOITS PHYSICIANS

**Birdsell Loan and Finance Co., Inc., Fools
Professional Men**

The Birdsell Loan and Finance Co., Inc., of Evanston, Ill., is engaged in the general collection business. It is reported that Mr. A. E. Birdsell, president of the company, stated that the company had also been engaged in financing past due accounts. The company was apparently chartered in December 1929 with an authorized capitalization of \$20,000, consisting of 1,200 shares of stock with no par value. We are informed that it began operation with offices in Jacksonville, Ill., where it was located for about two years, then moved to Rock Island, Ill., where it was located for about two years, and that the offices were finally moved to Evanston in September 1933.

The contract provisions of this company contain many clauses against which physicians have been warned in the columns of *THE JOURNAL* and *The Bulletin*. The physician who places his accounts in the hands of the Birdsell Loan and Finance Co., Inc., assigns and sells his accounts to the company subject to the company's discretion in settlement. He authorizes the company to take notes from debtors payable to the company and he further agrees "to receipt in full any account on which the company accepts note in lieu of cash after commissions have been deducted" and he has received the amount due him on the account. The physician constitutes, empowers and authorizes the company his sole agent for the purpose of negotiating any or all settlements of accounts listed with the company and he also constitutes, empowers and authorizes the company his sole agent and attorney in fact for the purpose of endorsing all papers of any kind or nature that may come into the company's possession. Furthermore, the physician agrees not to accept settlements or payments on any of the accounts listed with the company without forwarding the full amount of said payment to the company the day settlement or payment is made.

These citations to the contract provisions to which the physician subscribes when placing accounts with the Birdsell Loan and Finance Co., Inc., are sufficient to show that the contract is drawn largely in favor of the company and completely removes from the control of the physician the methods to be used in making collections. Moreover, it places the company in complete control of all moneys and papers.

Other organizations besides the American Medical Association have received numerous complaints from clients who allege

that they cannot obtain the moneys collected for them by this company. In this connection a printed article which appeared in "The Report of the Chicago Better Business Bureau," Feb. 22, 1934, is of interest.

'PROFESSIONAL MEN FOOLED BY BIRDSSELL COLLECTION DEAL

"Men are not born successful. Success is the outcome of achievement." These are the words of A. E. Birdsell, as quoted in *Buffalo Saturday Night* many years ago.

As for Mr. Birdsell's own achievements, he has recently been successful in fooling a multitude of business and professional men through his Birdsell Loan and Finance Company, Inc., now operating from 1513 Sherman Avenue, Evanston, Illinois, as a collection agency.

The Birdsell contract by means of which complainants feel they have been deceived is not exactly what it seems. The business or professional man, first of all, does not merely turn over his accounts to Birdsell's agency for collection. He assigns and sells them subject to the company's discretion in settlement.

The commissions demanded for the collection of delinquent accounts appear to be very moderate on first reading of the contract—only 25 or 30 per cent. However, the business man frequently fails to grasp the meaning of the word aggregate as used in the contract, which says that the company's commission is 25 per cent of the aggregate amount listed. Birdsell interprets this as meaning that if the client assigns accounts totaling \$2,000 for collection, and the company collects less than \$500, the entire amount collected is retained by the company as its commission. Many collection agencies have advised the Bureau that according to their experience seldom more than 25 per cent of the aggregate amount listed ever is collected by an agency on accounts of this nature.

Practically speaking, the business man who assigns his delinquent accounts to Birdsell's concern is saying, "These people owe me \$2,000. You may do with them as you wish—I have nothing to say about it. You can endorse checks and notes made payable to me, negotiate settlements and act as my sole agent in return for which you are to keep the first \$500 you take in. Until this \$500 has been collected by you, any money I may personally collect on these accounts is yours. After that anything realized over and above \$500 should be mine."

Business men who have complained to the Bureau have stated that the salesman represented that the company would mail to the client 75 per cent of all money collected as it came in. They have failed to grasp the significance of the word assigns.

Birdsell's concern formerly operated from Rock Island, Illinois. In 1932 a doctor in New York realized that he had been deceived and advised his debtors to pay the Birdsell company nothing. Birdsell wrote the following to one of the debtors: "If Dr. ———— thinks he is running our business, he is sadly mistaken, and if you use Dr. ————'s services in the future, I want you to bear in mind that he has not carried out his contract with us. We don't trust him and you are to judge whether or not you should."

The doctor took his complaint to his local Better Business Bureau and Birdsell's letter to the Bureau states: "I have no confidence in any Better Business Bureau which is indicated by the letter I am enclosing for your perusal, a copy of which I am enclosing to the clients. The letter enclosed was a malicious attack on Better Business Bureaus by J. L. Foreman of Foreman's National Detective Agency, Denver, Colorado, which has since been revealed as a local unit of ex-convict Logan Billingsley's anti-Better Business Bureau organization. (This organization included questionable investment operators, promoters, loan sharks, fraudulent users of the mails, and others who had reason to dislike Bureaus.)"

A letter of endorsement from Foreman and another from the "A. M. A. Detective Bureau" of Birdsell's own creation appear in the sales kit solicitors for the present enterprise have shown to prospects. One solicitor is said to have carried a letter of endorsement from the Chicago Better Business Bureau. The only letters the Chicago Bureau has addressed to Birdsell have been in connection with inquiries and complaints with the exception of one written in answer to Birdsell's refusal to provide the Bureau with information to be used in handling inquiries regarding his concern.

The Bureau's investigation of Birdsell's past activities indicates that in 1922 he formed the A. E. Birdsell Company, Inc., operating at 46 Builders Exchange, Buffalo, N. Y. On February 3, 1923, the *Buffalo Express* published a news article in which it was stated that he had left the concern with liabilities of \$91,000. This was evidently intended as a cooperative venture giving stockholders the right to buy coal and ice at a discount.

In 1927 Birdsell was employed by the United States National Adjustment Company, 3408 South Michigan Avenue, Chicago, another agency which has been generally complained against.

The Better Business Bureau, Inc., of Indianapolis reported a few months ago (December 1933) that it had received some serious complaints relative to this organization, all based on the company's high pressure methods of obtaining collection accounts and the methods used in making collections and handling the accounts.

The secretary of a state medical society in a Midwestern state reported that a representative of the Birdsell Company, soliciting business in other parts of the state, had showed a copy of a telegram supposed to be an endorsement of the company by the secretary of the state medical society. According to the secretary of the state medical society, the telegram was a complete forgery.

It is also stated by the same state medical society secretary that the Birdsell Company has practiced some peculiar methods in financing medical accounts, it is alleged that after securing a note for the amount of the medical account, signed by husband and wife, the company would then pay the physician 75 per cent of the amount of the note at once, but if the company failed to collect the note, the physician was required to refund to the company not the 75 per cent of the face value that was advanced to him, but the entire face value, in order to take up the notes

ANNUAL CONGRESS ON MEDICAL EDUCATION, LICENSURE AND HOSPITALS

Thirtieth Annual Meeting held in Chicago Feb. 12 and 13, 1934

DR. RAY LYMAN WILBUR, Stanford University, Calif.,
in the Chair

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

FEBRUARY 13—MORNING

Review of the Accomplishments of the Council on Medical Education and Hospitals

DR. RAY LYMAN WILBUR, Stanford University, Calif. The impact of the laboratory on American medical education began to effect significant changes about the time the American Medical Association brought the Council on Medical Education and Hospitals into being. The Council has seen the continuous battle of the science of medicine with the practice of the art of medicine; the application of a myriad of new facts in the everyday life of the physician; the lengthening and strengthening of the medical course; the acceptance of the professional schools of medicine by many universities; the building of research institutions, medical schools and capricious hospitals; and a nation accepting the principle of preventive medicine and inaugurating public health measures based on controlled experiments and experience rather than on traditions and prejudices. The records of the Council show a revolution in method, organization and administration carried on with the help of the organized medical profession. The laboratory began to knock at the door of every institution. It meant trained men, expensive instruments, adequate equipment, a lengthened curriculum. The American Medical Association, through THE JOURNAL under the leadership of Dr. George A. Simmons, began to print educational numbers. It presented facts. With the assistance of the Council a complete survey of medical education was made. The idea of classifying medical schools on a merit basis was brought forward.

A review of the accomplishments of the Council emphasizes certain outstanding inadequacies in present medical education. Medicine has kept up to date with scientific advance but is behind in response to the social changes brought about by industry and the application of science to all phases of social and governmental relationships. The American medical school and its associated hospitals have now reached the stage where a new national survey is required. Every institution should be again studied. A higher level has been reached. There is as great a gap between the best A schools and the weakest A schools as there was between the best and the worst of thirty years ago. This survey must include the following considerations: 1. A better development of graduate instruction so that all physicians may have available opportunity of keeping themselves up to date. 2. We must rid ourselves of the antique, the obsolete, and the unimportant in our medical courses. The curriculum must be stripped of all that is not essential. Our aim must be to train men how to practice medicine rather than to load them with great masses of information. 3. The newer social concepts for the care of the sick and particularly the significance of preventive medicine must be emphasized in the medical school. 4. There must be more adequate study of the normal with its many variations. 5. The teaching of obstetrics must go far beyond the ordinary techniques and include the care of the mother for months before

delivery. 6. The relationships of dentistry and of the nursing profession to medical education must be worked out. 7. Perhaps most significant of all is the need for dealing with psychology and aberrations of the mind from entirely new points of view. 8. Most careful study will be required of the relationships of the hospital to the medical school. The doctor of tomorrow will know the physiology of the normal human body will be alert to changes that may take place and will think in terms of keeping men well and efficient rather than in terms of treating a patient during the progress of disease.

The Philosophy of Professional Licensure

JUSTIN MILLER, J.D., Durham, N.C. The purpose of professional licensure is to secure to society the benefits that come from the services of a highly skilled group and on the other hand to protect society from those who are not highly skilled yet profess to be, or from those who, being highly skilled, are nevertheless so unprincipled as to misuse their superior knowledge to the disadvantage of the people. For the present at least society seems willing to permit the medical and legal professions to work out their own destinies and to use the method of licensure for further building up and strengthening our traditions of self government and public service. How long this attitude of society may prevail will undoubtedly depend on how convincing shall be our demonstration of willingness to render the highest degree of service.

The nature of professional service requires the existence of a relationship of trust and confidence. A professional man cannot treat such a relationship in a casual way, and the methods of licensure must be such as to insure the constant recruiting of men who are adequately trained to render skilled service and alert to accept the responsibility of protecting those whom they serve against spoliation. It is generally recognized as an obligation of a profession that it should render needed service to persons too poor to pay fees. In spite of the indifference of those professionals who are concerned solely with rendering service to paying patients, it is obvious that in the performance of the functions mentioned it is to be found a safeguard for the future of our professions. So long as the public is convinced that the members of a profession will make available to it at the earliest moment consistent with safety, every new discovery the public will give its loyal support. Whenever the public suspects laziness, incompetence or apparent unwillingness to assume responsibility for problems that have theretofore been assumed to lie within the field of a particular profession it will look to others for help. Thus may be developed a new skilled service or the public be despoiled by fakers. One of the greatest trials of the medical profession results from the encroachment of miracle working religionists and psychic and psychologic charlatans. And yet although it is generally known that many medical cases are mental rather than purely physical in character and although it is authoritatively stated that over 50 per cent of hospital beds are devoted to mental and nervous cases in some medical schools is found a strange resistance to the experimental work of psychology and stupid unwillingness to develop the field of psychiatry. Failure to do so is unfair to the public and to the profession.

With their backs to the wall the lawyers too are now using the method which the church once used to protect their borders—namely laws prohibiting others than licensed practitioners from practicing law. These unlawful practice acts have been passed in a number of states. In some states they have been decisively defeated, a clear indication of loss of public esteem and evidence of lack of that faith which is necessary to guarantee popular support of a profession. Professions like armies succeed by using militant offensive tactics. Many of the teachers in professional schools today are men entirely lacking in the practical experience that comes from actual contact with the world outside of university communities. Some are frankly disinterested in the relation of their professions to society and are even disinterested in the practitioners themselves.

It is quite possible for us in the educational group not merely to discover for those in the licensure group ability of the type which has been tested in the past but to answer almost any question one cares to ask concerning these neophytes who are in our care. With the backing which well regulated licensure gives we can establish such standards of education as licensure

requires The important question is whether those of us in whose hands now rests the destiny of the professions are really interested in the underlying philosophy of licensure and willing to establish the necessary procedures for properly determining, by adequate training and selection, those who are to follow us

DISCUSSION

ALPHONSE M. SCHWITALLA, SJ St Louis Any governmental authority necessarily labors under a series of all but prohibitive incapacities in fixing basic standards of selection for a profession The governmental authority is at times vastly remote not only from professional idealism but all too often even from that professional service which licensure by its very concept is intended chiefly to promote foster and develop for the public's welfare The governmental authority is subject to the vacillation arising from political favor and disfavor It is vested, and necessarily so, all too frequently in persons whose appreciation of professional life is limited to casual contact with members of the profession and among these all too frequently with the least representative members or at least with the less alert, less progressive and less capable members of the profession Governmental authority moreover, is concerned largely with the problems of integration of the claims and rights of one profession with those of another and even with the claims and rights of a profession with reference to the claims and rights of nonprofessional groups and while these conflicting claims and rights must be recognized by the state it can happen all too frequently that the safeguards for professional integrity may be jeopardized while the governmental authority under a temporary pressure is forced to give recognition to the nonprofessional interests Corollaries without number but with enormous significance for a professional life follow from such conflicts In general I believe, it would be quite fully recognized that while the abstract right to establish standards of selection must be granted to a governmental agency there will also be wide agreement on the principle that the state in establishing its basic standard of selection should not as a matter of prudence and as an evidence of its solicitude for the public welfare retain for itself the establishment of the criteria for licensure

What should be the relation between the governmental authority and the members of the profession in laying down the basic standards for licensure? Have we reached a time when we are prepared to accept the principle that the standards for licensure should under the delegated authority of the government be formulated by and even administered by the foremost members of the profession? In medicine we have already recognized the National Board of Medical Examiners as a professional agency whose disinterestedness and idealism are so obvious that many of the state boards have taken success in passing these examinations as *prima facie* evidence of a marked eligibility for licensure Graduation from an approved school of medicine has been suggested by some as a sufficiently effective selective procedure for establishing the qualifications for licensure This suggestion is somewhat premature The chief difficulties with this policy arise from the fact that even approved schools of medicine cannot or, at least do not universally take the position that the medical curriculum is necessarily an educational agent for such professional development of the prospective physician as will entitle him to the rights and privileges of medical practice within a given state Professional practice implies more than intellectual ability Serious questions have been raised as to the value of merely intellectual achievement as a preparation for the art of medicine I note that Dean Miller is at serious pains to show us that at Duke University the curriculum in law implies tests of character traits and moral fitness Much more is the medical curriculum interpretable as a testing agency of character traits social traits and moral traits But the difficulties arise when we are confronted with the necessity of using such information as we have about a student What school if the truth must be told has the courage to withhold its final approval of a student who after successfully passing through his examinations is still found to lack those traits of character which we all desire in our own personal physician? Is there not and will there not ever remain an extensive disagreement on the content of professional ideals and objectives? If the medical schools which are in intimate touch with a student throughout

the years of his preparation find it difficult to pronounce on the eligibility of a student for practice, how much more difficult must it not be for a state board to determine such eligibility The solution of this dilemma must ultimately lie in our basic philosophy of medical education A school of medicine must clarify for itself its own ideals and objectives It must submit these ideals and objectives to the public judgment so that the public may be aware of the school's claims The school must be held responsible for putting into its curriculum as well as into its extracurricular influence that measure of educative pressure which will mold the plastic individuals subjected to it into ever stronger and better men who will carry the overpowering burden of responsibility for the nation's welfare It would seem that the state board criteria for the eligibility for practice should contain not only the intellectual element which is tested so rigorously by the schools of medicine and by the state boards themselves but also a moral element for which the tests are still to be developed or which, if tests cannot be developed, must be taken for granted If the state boards do not exercise firmly disinterestedly and vigorously the power that has been vested in them in favor of or against those candidates whose eligibility or noneligibility has become apparent from such tests as are at our disposal, then all the refinements of modern psychology, of educational psychology, of vocational guidance, of confidential direction, are worse than useless The state board must in the last analysis be made up of such men as are able to carry the public responsibility imposed on them

Medical Education and Its Relationship to Society as a Whole

ROBERT G. SPROUL, LL.D., Berkeley, Calif It seems to be the accepted conclusion that there is today an oversupply of physicians in the United States In any profession an oversupply of practitioners means a powerful temptation to low ethical standards induced by desperation The law, encumbered with twice as many lawyers as are needed, has felt these effects, and on the commonwealth the effects have been disastrous Medicine has not come through unscathed Overcrowding has increased fee splitting the promotion of unnecessary services or of necessary services in an unnecessary expensive fashion, illegal operations, the employment of "runners," and other sordid by-products of a noble profession In combating these forces, far-reaching steps have been taken during the past quarter century The number of medical schools has been reduced from 160 with 64 graduates per hundred thousand of population to 66 schools with 36 graduates per hundred thousand of population The number of physicians trained has been reduced by 20 per cent although the contemporary increase in population has been 50 per cent, and the average age of the beginning practitioner has been raised from 22 to 28 years Nevertheless the supply still far outstrips the demand There is a strong movement deliberately planned, to realize more fully the advantages of restriction Studies are being made to show the number of physicians actually required to care adequately for our population Plans are on foot when these data are available to decrease the number trained and licensed to practice medicine to the point at which supply and demand are reasonably equalized In medicine, as in other fields, steps are being taken to limit the professional group, on the ground that discriminative selection is socially beneficial and that the individual is and ought to be of secondary consideration

These developments are counter to the democratic ideal which has hitherto controlled in the United States They will not be accepted without question by the American people With 16,000 eligible candidates clamoring this year to enter the medical schools of this country and Canada, and the doors closed arbitrarily in the faces of all but 6,200, plans to exclude still more so as to train and license only as many as may find employment will not, we may be sure prove acceptable to fond and irrational American parents We Americans have believed so thoroughly that all men are created equal that we attempt to keep them so throughout their lives and are actually in grave danger of making mediocrity the national ideal With such bases of selection as we now possess, we cannot be sure that our conclusions are not subversive of the best interests of society because they may exclude very good prospects and welcome rather ordinary ones What are we going to do about it? In

the first place certain natural checks are already beginning to be operative. Few things more helpful to professional education could be done than to determine the approximate needs of the state respecting each profession, disseminate this information widely and thereby, so far as possible, attain voluntary limitation of the numbers of candidates for professional work and a voluntary sorting of such candidates among the various professions. For all citizens up to a certain age level there should be a general training designed to raise the level of intelligence and to prepare them for living and making a living. This is the highly important task of the elementary and secondary schools including the junior colleges. The university and the four year college should be for those who are attracted to and show proficiency in scholarship, either for itself or as preparation for a profession. Here the people should be satisfied with nothing less than the best attainable institutions and the best attainable students. A university's first duty in the professional field is to select and educate those who give promise of becoming the ethical and scholarly leaders. The training of adequate numbers must always be an important but secondary obligation. The general acceptance of these simple principles by the American people would save ages of time and fortunes of money without weakening the foundations of democracy. The second step should be in the direction of adjusting the distribution of medical service, in order that it may meet more fully the health needs of the public before further limitation of the number of medical school entrants or graduates is undertaken.

Some grumbling has been heard concerning the advanced age of medical graduates, but this seems to me inevitable if not desirable. The overwhelming majority of medical graduates will practice the art rather than the science of medicine. They will need for success and happiness not only knowledge of the fundamental principles of science and of their application to other branches of knowledge but also a taste for history, philosophy, literature and art that will stamp them as cultured gentlemen. More physicians are failing because they are not the kind of person one wants to have around than because of a lack of technical skill.

There is imperative need for the reversal of the recent trends that have been separating the doctor from the individual and the family and have been bringing on medicine the criticism of treating diseases rather than human beings. Concentration on pathologic conditions has tended too much to obscure the normal human being and the preservation of the normal state of health. A general practitioner should be competent to take the complete responsibility for perhaps 90 per cent of all his practice. The University of California is placing special emphasis on the instruction of medical students in the normal physiology and biochemistry of the body. Our students are being taught to recognize health before sickness and to realize the interrelationship of the body's organs, especially those delicate balances of the life processes that exist between the nervous and the mental, in one scale, and the physical, in the other. Only when they have become well acquainted with health are students introduced to those deviations from the normal which produce sickness. To facilitate this manner of approach fourth and fifth year students are obliged to assume entire responsibility for patients. Instead of looking on while their instructors make decisions, they are required to make the decisions themselves. Students are discouraged from too early specialization. They are encouraged instead to learn to use specialists in connection with a general practice. In the coming era, doctors must face social responsibility for the community and act as trustees for society in planning their objectives. Thus will medicine be strengthened and extended and implemented to serve a larger constituency on a basis that will yield adequate returns to its practitioners.

All the sciences are leading up to a better understanding of the laws of life and a consequent improvement of the physical, mental and moral powers of man. Medicine, preventive and curative, promises to do more and more for human welfare. If legislation and civil administration will keep up with science, if knowledge can be controlled by ethical standards and applied with temperance, if the organizations and attitudes that you and I represent can be given support, encouragement and opportunity there is no reason why the community of tomorrow may not be altogether free from most of the foes which in this and former generations have slain their tens of thousands.

DISCUSSION

DR E P LYON, Minneapolis. I was struck by the discussion of the alleged right of the student to pursue a medical course or any other course. I could make a strong case for denying this right, on the basis of social rights generally, but I prefer to make the claim that no student has a right to this on the same basis as automobiles or trips to Europe. No student has a right to something more than half the expense of which rests on the public. I think there is need for a great deal more clarity as to what our rights of education are. Those rights are of recent origin. I may look on any public thing and say "I partly own this fire station. I partly own this army camp," but to go into that fire station or army camp and use the facilities there is not my right. It is the right of people chosen to use them. I think that principle will hold in regard to a hospital and its facilities and opportunities for education. I think every dern here will say his chief business is the training of general practitioners. But if it is implied that the education of specialists of public health people, of researchers should be a separate function then I wish to demur. I think the education of specialists with general practitioners is a good thing and I can demonstrate it from experience. I am sure that the carrying on of research as a part of the program of a medical school and as accessory to its teaching is what gives spirit and gives something more than the application of the so called practical to the man who goes out.

The Restoration of the General Practitioner

DR DRAY LEWIS, Baltimore. This article appears in full in this issue page 977.

DISCUSSION

DR JAMES B. HERRICK, Chicago. The general practitioner of the old type cannot and will not be put back and I do not think the old type practitioner should be put back in the present condition of medical knowledge. The general practitioner of the old type has passed very largely and he had to pass. The mass of medical knowledge that came on the world a few decades ago was so huge that it made it impossible for any one mind to grasp it all or to practice in accordance with that knowledge. The day, in other words, of the know all doctor and the do all doctor has passed. There is another reason why the old type medical practitioner cannot be reestablished. People have become health conscious, they know a great deal more about medicine than they formerly did and they are demanding not an average type of medical service but the best. They go where they think they get it. They are apt to go to the specialist, and the good roads, the telephone and the automobile make it a simple thing for them to do that. I object as Dr Lewis does to the term "general practitioner." We cannot restore by resolution a practitioner to his former position. He must restore himself, and he is doing it. There is developing a new type of family doctor and that type is going to succeed if he is qualified and only if he is qualified. The qualities that are going to count are character, energy and personality. The other qualification is that he must possess knowledge that he gets by study, by the guidance of teachers in college, during his internship and what so many practitioners forget, by studying long and hard through the years of practice. There is a good deal of overstandardization in medical schools. Dr Lewis is right when he says that there are a great many unnecessary non-essentials that are dwelt on. Teachers should stress more the essentials and fundamentals. Somewhere in the undergraduate course there should be not an opportunity for a man to do intensive work on some one subject, but he should be compelled to do it. Many medical graduates do not know the meaning of the word 'thorough' but when a man has gotten away from his textbooks and has been forced to look at monographs and original articles and to look in the laboratory at the section under the microscope and to attend the postmortem and has gone as deeply into the subject as the time and opportunity will permit, he is a far safer man in the community than the man that we have to dub 'mediocre' who is versed simply in the essentials. I know of no more dangerous man in the community than the mediocre practitioner who does not know his own limitations who does not know the limitations of method, the dangers and limitations of an operation. The third requirement is that the practitioner should be qualified in the art of medicine.

his ability to apply knowledge, which he learns by experience at the bedside. I have no quarrel with the research man, but practitioners are not going to learn how to practice in the research laboratory or in the library. The best textbook for the practitioner of medicine is the patient. Albert said that practitioners are made at the bedside. Neisser said that pathology is the mistress of us all. Osler said: To study the phenomena of disease without books is to sail an uncharted sea, while to study book without patients is not to go to sea at all."

(To be continued)

MEDICAL BROADCASTS

National Broadcasting Company

The American Medical Association broadcasts on a coast-to-coast network each Monday afternoon from 4 to 4:15 Central standard time (5 o'clock Eastern standard time, 3 o'clock Mountain standard time, and 2 o'clock Pacific standard time).

The next three broadcasts will be as follows:

- April 2 What Is Health? W. W. Bauer, M.D.
- April 9 Peculiar Accidents W. W. Bauer, M.D.
- April 16 Bird with a White Breast, W. W. Bauer, M.D.

Columbia Broadcasting System

The Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Central standard time. The next three broadcasts will be as follows:

- April 5 Smog W. W. Bauer, M.D.
- April 12 Pretty Polly W. W. Bauer, M.D.
- April 19 More Health Delusions W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

State Medical Meeting at Birmingham, April 17-19—The sixty-seventh annual session of the Medical Association of the State of Alabama will be held in Birmingham April 17-19, under the presidency of Dr. James R. Garber, Birmingham, and with the Jefferson County Medical Society as host. A pre-convention meeting will be held in Tuscaloosa April 16 under the auspices of the Tuscaloosa County Medical Society. The following symposiums are included on the program of the regular meeting:

- BRONCHIECTASIS**
 - Dr. Allan W. Blair, Tuscaloosa
 - Dr. Edgar G. Givhan, Jr., Birmingham
- ANEMIAS OF EARLY INFANCY**
 - Dr. George S. Graham, Birmingham
 - Dr. Benjamin Hughes Kennedy, Jr., Birmingham
 - Dr. Charles E. Abbott, Jr., Tuscaloosa
- STOMACH AND DUODENAL ULCER**
 - Dr. Edward S. Sledge, Mobile
 - Dr. Isaac M. Gravlee, Mobile
 - Dr. Lloyd Noland, Fairfield
 - Dr. Seale Harris, Birmingham
- CANCER**
 - Dr. Karl F. Kesmodel, Birmingham
 - Dr. Marion Toulmin Gaines, Mobile
 - Dr. Joseph Alston Maxwell, Tuscaloosa
 - Dr. Neal E. Sellers, Anniston
- MEDICAL ECONOMICS**
 - Dr. Bert W. Caldwell, Chicago
 - Dr. Roscoe G. Leland, Chicago

Other guest speakers will include Drs. Jay Arthur Myers, Minneapolis, on 'Diagnosis, Treatment and Prevention of Tuberculosis'; James R. McCord, Atlanta, Ga., 'Syphilis and Pregnancy'; Russell L. Cecil, New York, who will give the Jerome Cochran Lecture on 'The Present Trend in the Study of Arthritis and Rheumatic Diseases'; and Morris Fishbein, editor of THE JOURNAL, Chicago, who will address a public meeting Wednesday evening on 'The Trend of the Times.' Other speakers will include Dr. James P. Collier, Birmingham, on 'Common Indications for Splenectomy,' and James G. McAlpin, Ph.D., Montgomery, 'Undulant Fever.' The title

of Dr. Garber's presidential address is "The Physician as Scholar and Statesman." The presentation at the Birmingham Little Theater of a three act play, "Men in White," with the compliments of the Jefferson County Medical Society, will conclude the session.

CALIFORNIA

Dr. Moodie Dies—Roy Lee Moodie, Ph.D., anatomist and paleontologist, died in Hollywood Hospital, February 16, following a fall on a cement floor. Born in Kentucky in 1880, he received his bachelor's degree at the University of Kansas in 1905 and the degree of doctor of philosophy from the University of Chicago in 1908. He held teaching positions in biology and zoology from 1908 to 1913, in which year he became professor of anatomy at Baylor University, Dallas, Texas. He was identified with the University of Illinois College of Medicine from 1914 until 1923, first as instructor in anatomy and finally as associate professor. Following a sabbatical year spent in research in southern California, he continued with the University of Illinois as associate professor of anatomy and research librarian until 1928, when he became professor of paleontology at the University of Southern California College of Dentistry. He had written several volumes on his specialty.

Health Insurance Proprietor Sentenced—Harry Kramer, head of five racketeering health insurance associations, must serve from one to two years in San Quentin Prison, according to newspaper reports. Sentence was passed, March 3, by Superior Judge Fred V. Wood of Alameda County. In addition, Kramer was fined \$5,000. E. L. Knotts, one of his salesmen, who had also pleaded guilty, was fined \$200 and sentenced to serve ten months in the county jail. Harry Blankenstein, another salesman, went on trial, March 20, following his plea of not guilty. Sixteen other alleged agents are fugitives under indictment, the report stated. Kramer admitted that during three years' operations of his companies only \$71.05 was paid out in health and accident claims. He also admitted that he had no reserve fund from which to pay claims. During ten months of 1933, he collected \$8,934 from clients. An article describing some of the California health insurance schemes appeared in THE JOURNAL, March 24, page 935.

DELAWARE

Bill Introduced—H. 124 X proposes that both parties to a prospective marriage as a condition precedent to the issue of a license to wed, must present to the official authorized to issue such a license a certificate from a licensed physician that both parties are free from syphilis, gonorrhea and tuberculosis.

Society News—Dr. Robert F. Ridpath, Philadelphia, discussed sinusitis before the New Castle County Medical Society, March 20. The society was also addressed by Drs. Ira Burns on 'Atelectasis and Collapse of the Lungs' and Robert W. Tomlinson, Wilmington, 'Galactose and Levulose in Liver Function.' Dr. Ralph M. Tyson, Philadelphia, spoke, February 20, on 'Infant Feeding and Nutrition.'

DISTRICT OF COLUMBIA

University News—Dr. Edward Francis of the National Institute of Health gave the February lecture in the Smith-Reed-Russell series at George Washington University School of Medicine, on "Study and Control of Tularemia." Dr. John M. Wheeler, New York, delivered the March lecture, on 'Exophthalmos.' Dr. Elliott P. Joslin, Boston, addressed the students, February 12, on diabetes.

Personal—Dr. William P. Herbst, Jr., has been appointed professor of clinical urology at Georgetown University School of Medicine and chief of the Georgetown urologic service of the Gallinger Municipal Hospital. Dr. Herbst graduated at Georgetown in 1915. He was formerly associated with the University of Minnesota School of Medicine.—Dr. Daniel J. Finucane has been appointed superintendent of the new Children's Tuberculosis Sanatorium being erected near Glendale, Md.—Dr. Joseph L. Gilbert was recently appointed alienist of the District of Columbia.

Health at Washington—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended March 17, indicate that the highest mortality rate (21.6) appears for Washington, and the rate for the group of cities as a whole was 12.6. The mortality rate for the corresponding period last year for Washington was 15.6 and for the group of cities as a whole, 12.1. The annual rate for eighty-six cities for the eleven weeks of 1932 was 12.7 as against a rate of 12.4 for the corresponding period of the previous year. Caution should be used in the

interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

ILLINOIS

Society News—Dr Geza de Takats, Chicago spoke before the Sangamon County Medical Society, March 1 on 'Diagnosis and Management of Peripheral Vascular Disease'. At a meeting of the McLean County Medical Society in Bloomington March 14, Dr Dean Lewis, Baltimore President, American Medical Association discussed 'Differential Diagnosis of Tumors of the Breast'. A discussion of pneumonia was presented at the meeting of the LaSalle County Medical Society, February 23, by Drs William S Middleton and Joseph W Gale, Madison, Wis. Speakers before the Madison County Medical Society in Highland March 2 were Drs Duff S Allen and Julius Jensen, St Louis on 'Thyroidectomy in Decompensated Heart Disease' and 'The Thyroid as the Regulator of the Circulatory System' respectively. Dr Frank Smithies, Chicago addressed the Mason County Medical Society, Decatur February 23 on 'mebrasis'. At a meeting of the Will-Grundy County Medical Society March 21 Dr Oscar T Schultz Evanston spoke on 'Agranulocytosis'. The Fulton County Medical Society was addressed at Canton March 21 by Dr Robert W Kecton Chicago on 'diabetes'. Dr James A Warner St Louis discussed 'bacterial diseases before the Williamson County Medical Society in Herrin March 13.

Chicago

Society News—The Chicago Urological Society was addressed, March 22, by Drs Robert H Herbst and George O Baumrucker, among others on a colorimetric test for renal function. Speakers before the Chicago Society of Internal Medicine, March 26 included Dr M Herbert Barker on 'Alveolar Oxygen Saturation by Nasal Catheter and Tent Administration'.

INDIANA

Society News—At a meeting of the Tippecanoe County Medical Society Lafayette March 8, Dr Howard C Billenger Chicago spoke on the ear, nose and throat in general medicine. Speakers before the Jay County Medical Society in Portland March 2, were Drs James M Pierce and Carl A Koch Cincinnati, on 'Postpartum Care and Postnatal Care and Birth Injuries'. Dr Herman L Kretschmer Chicago discussed 'Changing Trends in the Treatment of Bladder-Neck Obstruction' before the St Joseph County Medical Society in South Bend February 21. Dr Harry O Jones, Berne, talked on obstetrics before the Adams County Medical Society February 24. At a meeting of the Vermillion County Medical Society, February 21, Dr Gordon W Batman Indianapolis, spoke on 'Fractures and Dislocations'. Dr George A Collett Crawfordsville spoke before the Fountain Warren County Medical Society in Hillsboro February 1, on 'Early Diagnosis of Acute Appendicitis'. At a meeting of the Jasper Newton County Medical Society in Morocco, January 26 Dr Benjamin H Orndoff, Chicago discussed radiation therapy with special reference to cancer of the breast. Dr Joseph L Baer Chicago addressed the Elkhart County Medical Society in Elkhart February 8 on 'Normal Obstetrics in General Practice'. Speakers before the Shelby County Medical Society March 7 were Drs Alois B Graham and Joseph W Ricketts, both of Indianapolis on 'Carc of Rectal Diseases by the General Practitioner' and 'Cancer of the Rectum' respectively. Dr William H Olmstead St Louis discussed 'Early Changes of Arteriosclerosis in the Human Body' before the Vanderburgh County Medical Association, February 13.

IOWA

Society News—Dr Frank M Conlin, Omaha addressed the Woodbury County Medical Society February 15 in Sioux City, on 'A Statistical Study of 616 Cases of Diabetes, with Particular Reference to Surgical Complications'. Dr Leo G Rigler, Minneapolis addressed the Cerro Gordo County Medical Society, February 20 on 'Benign and Malignant Tumors of the Stomach from the X-Ray Standpoint'. At a meeting of the Clinton County Medical Society in Clinton, March 1 Dr Clifford J Barborka Chicago, spoke on 'The Present Conception of the Relation of Diet to Health and Disease'. Dr Nathaniel G Alcock Iowa City spoke before the Black Hawk County Medical Society March 20, on renal malignancies. Dr John H Musser New Orleans will address the Linn County Medical Society April 13 on 'treatment of the anemias'.

KANSAS

Dr Scammon Gives Porter Lectures—Richard E Scammon, Ph D, dean of medical sciences, University of Minnesota School of Medicine, Minneapolis, will deliver the Porter lectures of the University of Kansas School of Medicine, April 2-3. One lecture will be given at Lawrence and the other two at Kansas City. The lecture at Lawrence is to be of a semi-popular nature, the other two more technical. The titles are 'The Plague in Western Europe' (Kansas City), 'The Guild of Medicine' (Lawrence), and 'How Measurement Came Into Medicine' (Kansas City). In 1918 the late Dr Joseph L. Porter Paola, bequeathed to the school about \$30,000 to found a fellowship and for such other purposes as the medical faculty recommended. A portion of the income of this fund has been used to support an annual series of lectures, known as the Porter Lectureship in Medicine. The first course was given in 1930 by Dr Jewell G Barker Baltimore the second by Dr Joseph Collins New York and the third by Dr John Shelton Horsley, Richmond Va.

KENTUCKY

Bills Enacted—The following bills have become law with out the governor's approval. H 388 forbidding the possession or sale of marihuana except on the prescription of a licensed physician, dentist or veterinarian and H 662, the uniform narcotic drug act.

Extension Lectures—Dr Joseph Garland Sherrill and Philip I Barbours, Louisville gave a group of extension lectures in the series sponsored by the Kentucky State Medical Association at Greenville February 1. Dr Sherrill discussed cancer of the breast, peptic ulcer complications of gallbladder disease and appendicitis. Dr Barbours, eczema and asthma relation of chorea to rheumatism juvenile tuberculosis and problems of adolescence.

MARYLAND

Personal—Associates of Dr Harry Friedenwald emeritus professor of ophthalmology, University of Maryland School of Medicine, Baltimore, gave a surprise dinner in his honor, February 3. About forty physicians were present including members of the staff of the Baltimore Eye, Ear and Throat Hospital where Dr Friedenwald has been associated for thirty six years.

Baltimore Health Record—The year 1933 achieved the lowest death rate Baltimore has known 1305 as against 1313 in 1932. A new record of 606 was also established for infant mortality as compared with 62 for 1932. Smallpox has been absent from Baltimore for the last four years. The year also marked new low death rates for diphtheria (0.7 per hundred thousand of population) and typhoid (0.36). The tuberculosis death rate was 78.2 as compared with an earlier rate of 86.2. The six leading causes of death in the city for 1933 were heart disease, chronic nephritis, cancer, pneumonia, cerebral hemorrhage and tuberculosis.

MICHIGAN

Personal—Dr James T Redwine was recently appointed superintendent of the Michigan Farm Colony for Epileptics at Wahyamega. Dr John W Handy, Flint, was guest of honor at a dinner given by the Genesee County Medical Society, February 14, in observance of his completion of fifty years in the practice of medicine. Speakers included Drs Walter H Winchester, Charles H O Neil Ray S Morrish and Dr Handy. Dr James A Olson has been named school physician of Flint succeeding Dr Stephen M Gclenger, who has resigned to accept a position with the Herman Kiefer Hospital, Detroit. Dr Augustine T Holcomb Novi, recently completed fifty years as a practicing physician.

MINNESOTA

Hospital News—A sanatorium for tuberculosis patients to cost \$250,000 will soon be constructed by the federal government on a site of forty acres near Walker. The property was recently deeded to the government, it is reported.

Symposium on Cancer—The occurrence of cancer in private practice and the available means of treatment will be the theme of the annual symposium on cancer of the Minneapolis Surgical Society in the Hennepin County Medical Society Auditorium Minneapolis, April 5. Introductory remarks will be offered by Drs Kenneth Bulkley, president and James Frank Corbett. Dr Ivar Sivertsen will present a report of the survey of the incidence of cancer in Minneapolis and of cases treated in private practice. Reports of roentgen therapy

as an adjunct to surgery and of facilities for high voltage roentgen therapy in Minneapolis will be presented by Dr Arthur A Zierold in collaboration with Drs Russell W Morse Walter H Ude, Gustaf T Nordin and Robert G Allison Dr Martin Nordland will present the report on the use of radium as an adjunct to surgery and of facilities for radium therapy in Minneapolis, with the following collaborators Drs William T Peyton, Lawrence M Larson, Charles R Drake, Aloysius S Fleming and Samuel L Sweitzer Concluding the program will be an open forum report of five year cases by members of the society, only patients free from signs or symptoms five years after removal of a malignant growth to be included

MISSISSIPPI

Bill Enacted—H 553 has become a law, authorizing the board of supervisors of Harrison County to make a general levy, not to exceed one half of one mill, on all the taxable property in the county, to provide funds for charitable hospital purposes

NEVADA

Society News—A symposium on cancer of the breast constituted the meeting of the Washoe County Medical Society in Reno, February 13, speakers included Drs Lawrence Parsons, George Stevenson Sharp, Pasadena Calif, and Alson R Kilgore San Francisco January speakers were Drs Alfred W Macpherson, Sparks and Albert R Da Costa Jr, Reno on 'Spinal Anesthesia' and 'Ideal General Anesthesia' respectively

NEW JERSEY

Bill Enacted—A 132 has been enacted as Chapter 40 Laws 1934, providing that nothing in the state emergency act shall be construed to prohibit or limit any licensed physician occupying a position as a state, county, municipal or school physician from being compensated by the state for the care and treatment of emergency relief patients

Record Low Death Rate—New Jersey attained the lowest death rate in the history of the health department in 1933 10.03 per thousand of population The rate for diphtheria, 12 per hundred thousand, and that for tuberculosis 54.9 were the lowest ever reached for those diseases Infant mortality was 46.5 per thousand live births, the lowest rate ever reached Cancer deaths occurred at a rate of 115.8 per hundred thousand of population, and deaths from automobile accidents increased from 115.8 in 1932 to 1,207 in 1933

Bills Introduced—S 207, to supplement the medical practice act, proposes to require the board of medical examiners to examine for a license to practice medicine and surgery without restriction any holder of a limited license 'who shall have heretofore completed a four year high school course of study or its equivalent and shall have heretofore studied in a legal sized incorporated college or colleges during at least two different calendar years the subjects of physics chemistry (organic and inorganic, including laboratory work in both) pathological chemistry, English composition and literature American and European history, bacteriology (both in class and laboratory), psychology and sociology, and who shall have heretofore for a period of not less than five years studied under the supervision of and consulted with a graduate medical doctor holding the degree of M.D. A 373 proposes to appropriate \$10,000 to the state department of health for the purchase of diphtheria toxoid and/or toxin or antitoxin and smallpox vaccine The department is to distribute these antitoxins and vaccines free in accordance with its rules and regulations

NEW YORK

Bills Passed—A 1377 has passed the assembly proposing to prohibit a corporation from using the word Doctor or Dr as a part of its corporate name S 348 has passed the senate proposing to make it unlawful for any person to give any false call for a physician or hospital

Bills Introduced—S 1377 and A 1873 to amend the workmen's compensation act propose to authorize the industrial commissioner to establish a schedule of charges and fees for medical treatment and care rendered injured employees This schedule is to be prepared by the commissioner on the recommendations of the state medical society but he is to give consideration also to the opinions of other interested parties A 1858 and S 1376 propose to create a state commission to consist of two members of the senate two members of the assembly and two members to be appointed by the governor to make a comprehensive study of the narcotic habit-forming drug problem and of the federal and state laws relative to narcotic drugs S 903 to amend the public health law in relation to

sanitary regulations and amendments to the sanitary code proposes that except in case of a public emergency no sanitary regulation shall be adopted by the public health council or by the commissioner of health which shall in any way curtail or limit the sale of milk or cream because such milk or cream is obtained from cows suffering from Bang abortion disease until such time as provision has been made for the disposal or destruction of such cattle and the payment of indemnity therefor to the owners thereof A 1357 proposes to make it a felony for any physician, by operation or otherwise, to change willfully the markings of a finger or thumb of any person so as to affect such person's finger prints This proposed law, however is not to apply to cases in which an operation is necessary to repair a deformity caused by congenital malformation disease or accident A 1719 proposes that no nurse employed in any state county or city hospital or in any hospital supported in whole or in part by public funds shall be allowed to work more than eight hours in any one day, and eight consecutive hours of work in any twenty-four hours is to constitute a legal day's work for any such nurse S 1375 and A 1824 to amend the law relating to registered nurses propose to require applicants for such registration to be citizens of the United States

New York City

Anesthetists Honor Dr Matas—The American Society of Regional Anesthesia celebrated its tenth anniversary, February 27 with a meeting in honor of Dr Rudolph Matas New Orleans a pioneer in the introduction and advancement of modern nerve block technique Dr Matas addressed the society on 'Local and Regional Anesthesia A Retrospect and Prospect'

University News—Dr Jean R Oliver, professor of pathology Long Island College of Medicine has received a grant of \$1,000 from the Josiah Macy Jr, Foundation for continued studies on the pathology of Bright's disease—A plaque of the late Dr Virgil P Gibney made by one of his former patients was presented to the College of Physicians and Surgeons Columbia University, December 9 by the class of 1898 Dr Gibney was a member of the faculty from 1890 to 1917—Robert Thorne, president of the Neurological Institute since 1924, died of pneumonia, March 6 aged 69 Mr Thorne, an attorney directed a campaign in 1927 to raise funds for the new building which is now a part of the Columbia University-Presbyterian Medical Center

Memorial to Dr Salmon—A bas relief portrait of the late Dr Thomas W Salmon was presented to the New York Psychiatric Institute and Hospital Columbia-Presbyterian Medical Center January 27, by the Thomas William Salmon Memorial Committee Dr Clarence O Cheney director of the institute presided at the ceremony, Dr William L Russell, professor of psychiatry, Cornell University Medical College made the presentation, and Dr Frederick W Parsons, Albany, commissioner of the state department of mental hygiene, accepted the memorial in the name of the state Governor Lehman sent a message pointing out that it was largely through Dr Salmon's efforts that the state and the university joined forces to establish the institute On the memorial tablet is the following inscription

Professor of Psychiatry Columbia University 1921-1927 Beloved Physician Teacher Mental Hygiene Leader Whose Vision Guided the State and the University in Placing Here This Psychiatric Institute and Hospital

NORTH CAROLINA

Hospital News—A twenty bed hospital, equipped for general medical and surgical treatment, was opened, Nov 16, 1933, at Murphy by Dr Robert W Petrie

Professor Appointed—Dr Raymond S Crispell Kingston N Y, has been appointed associate professor of neuropsychiatry at Duke University School of Medicine, Durham A graduate of Cornell University Medical School in 1920 Dr Crispell has served on the staff of Bloomingdale Hospital White Plains, N Y, Bellevue Hospital, New York City, and as medical director of Sahler Sanitarium Kingston

Society News—Dr H Kennon Dunham Cincinnati addressed the Mecklenburg County Medical Society, Charlotte February 6, on 'Clinical Aspects of Pulmonary Emphysema' Dr Clyde M Gilmore Greensboro was the guest speaker January 16 on 'The Present Conception of Coronary Disease'—Dr Alva B Craddock discussed amebic dysentery at the meeting of the Buncombe County Medical Society, Asheville February 5 The speaker, January 15 was Dr Joseph B Greene on cancer of the larynx—Dr Addison G Brenner, Charlotte was guest speaker before the Guilford County Medical Society Greensboro January 3 on 'Anastomosis of the Gastro-Intestinal Tract with the Use of the Pile Clamp'

OHIO

Dr Sollmann Honored—The staff of Western Reserve University School of Medicine, Cleveland, gave a luncheon in honor of the sixtieth birthday of Dr Torald H Sollmann, dean of the medical school, February 10, at the Cleveland Club. A decorated parchment manuscript in a pinseal folder hand tooled in gold was presented to Dr Sollmann, inscribed with a tribute written by Dr Howard T Karsner and signed by his associates. Dr Sollmann, a native of Germany, was graduated from Western Reserve in medicine in 1896 and has served as a member of the staff continuously. He was made professor of pharmacology in 1904 and dean in 1928.

New Health Commissioners—Dr Hazel L Sproull, West Union, has been appointed health commissioner of Adams County, succeeding Dr Samuel J Ellison, who had served fourteen years.—Dr Charles E Thompson Mingo, has been appointed health officer of Champaign County after a lapse of several months in which the county was without a health head because of lack of funds.—Dr Francis M Teeple, Fremont has been named health officer of Sandusky County.—Dr James B Naylor, Malta, recently resigned as health officer of Morgan County and was succeeded by Dr Arnold O Abraham McConnellsville.—Dr Frederick S McGee was appointed health commissioner of Marietta in January.—Dr Frank R Dew, Barnesville, health officer of Belmont County for eleven years, has retired from the office.—Dr William L Faul, Russellville, has succeeded Dr John G Anderson, Fayetteville, as health officer of Brown County.

OREGON

Physician Sentenced—Dr Richard Neubauer Portland was sentenced recently to seven years in the United States Penitentiary, McNeil Island, Wash, for violation of the Harrison Narcotic Act.

State Board of Health Elects—Officers of the state board of health elected in Portland in February are Drs Albert Mount, Oregon City, president, Joseph P Brennan Pendleton vice president, and Frederick D Stricker, Portland, secretary.

Society News—Dr Salvatore P Lucia, San Francisco addressed the Portland Academy of Medicine, February 8, on "Diagnosis of Conditions Presenting Enlargement of the Spleen"—Drs Emil D Furrer and Arthur F Barnett, Eugene, addressed the Central Willamette Medical Society, Eugene, February 1, on 'Present Day Uses of Vaccines and Serums' and "X-Ray and Radium Therapy in Malignancy," respectively.

PENNSYLVANIA

False Claim of Graduation—It is reported that a man named Andrew A Stamatiades claiming to be a graduate of Columbia University College of Physicians and Surgeons has been serving as intern at a hospital in Pennsylvania. Inquiry of the university revealed that a man by that name had taken several courses there in 1929 and failed in them all. It was reported in 1931 that he returned to the medical school and attended classes for a time without being registered, when this was discovered, doormen were ordered not to admit him.

Anthrax in Delaware County—Several cases of anthrax occurred in the mill village of Sackville, Delaware County, within the past year. The state health department reports that all the cases were contracted within the mill or its immediate environs. About half the 200 inhabitants of Sackville worked in the woolen mill. The first case of anthrax, which occurred in March 1933 was fatal, and the six persons infected since that time have recovered. Antitoxin was given in all cases, extra large doses being given in the six later cases. All cases were in mill workers except two in children who were found to have played about the mill in spots where waste had been incompletely incinerated. Through the cooperation of the state department of labor and industry, safety appliances in the mill were reviewed and necessary improvements were made.

Philadelphia

Interns' Night—The Philadelphia County Medical Society designated its meeting, March 14, as "interns' night, intended as a stimulus to and appreciation of all interns." From the Philadelphia General Hospital, speakers were Drs Albert Behrend, on "Pneumothorax in Pneumonia", John L Armbruster, 'Diabetes The Patient, Physician and Hospital', James Greenwood, Jr, 'Hypoglycemia as a Cause of Mental Symptoms,' and Jack W P Love, "Preliminary Report of the Clinical Application of Bacteriophage." From the Episcopal Hospital, Dr Webster H Brown spoke on "Treatment of Fractures of the Lower Third of the Leg" and from Pennsylvania Hospital, Dr John C Ullery, on 'Favism'.

RHODE ISLAND

Record Low Mortality Rate—Rhode Island's death rate in 1933 was 11.1 per thousand of population the lowest ever recorded since reliable statistics have been kept, the state public health commission reports. Similarly the infant mortality rate, 55.9 per thousand live births, and the birth rate, 14.4 per thousand of population, were the lowest ever known. For the first time since 1879, no deaths from measles were reported in 1933.

Bills Introduced—S 177, to amend the medical practice act, proposes that in an appeal from an order of the board of medical examiners refusing to issue or revoking a license to practice medicine, the supreme court may review the evidence presented before the board and may in its discretion affirm, overrule or modify the order of the board but the order shall remain in full force and effect during the pendency of the appeal. H 816 and S 141 propose to give to every hospital supported in whole or in part by charitable contributions or endowments, which cares for a person injured through the negligence of another a lien on all claims, rights of actions, judgments settlements or compromises accruing to such person by reason of his injuries.

SOUTH CAROLINA

Bill Passed—S 1698 has passed the senate authorizing the sexual sterilization of inmates of state institutions who are afflicted with any hereditary form of insanity that is recurrent idiocy, imbecility feeble-mindedness or epilepsy.

TENNESSEE

State Meeting at Chattanooga, April 10-12—The annual meeting of the Tennessee State Medical Association will be held in Chattanooga April 10-12, under the presidency of Dr Hiram B Everett, Memphis. A feature of the meeting will be a symposium on management of common traumatic cases in which participants will be Drs William Battle Malone, Memphis, Edward T Newell, Chattanooga, Duncan Ewe, Jr, Nashville, and Edgar F Fincher, Atlanta, Ga. Guest speakers in addition to Dr Fincher will be Drs Rosco G Leland, director Bureau of Medical Economics American Medical Association, Chicago on "Causes of Professional Unrest," Fred W Rankin, Lexington, Ky, 'Diagnosis and Prognosis Following Treatment of Cancer of the Rectum' and Henry F Vaughan, Dr P H, Detroit, 'Preventive Medicine from the Family Physician.' Among Tennessee physicians listed on the tentative program are:

Dr Frank Alloway, Kingsport Peroral Endoscopy and Gastroscopy
Dr Cassius W Friberg, Johnson City Fetal Indications for Termination of Pregnancy
Dr Oliver W Hill, Knoxville Purulent Pleuritis in Children
Dr Marcus G Spingarn, Memphis Perinephritic Abscess
Dr James W McClaran, Jackson Postoperative Pulmonary Complications
Review of the Literature
Dr George R Livermore, Memphis Abdominal Pain A Symptom Often Referable to the Kidney
Dr Joseph P Gilbert, Nashville Psychopathic Personalities and the Law
Dr William C Dixon, Nashville Surgical Treatment of Uterine Prolapse

The Tennessee State Pediatric Association and the Tennessee Academy of Ophthalmology and Otolaryngology will hold their annual meetings, Monday, April 9. The annual banquet will be at the Hotel Patten, Wednesday evening, April 11.

TEXAS

New Societies Organized—Physicians of Cass and Marion counties recently organized the Cass-Marion Counties Medical Society to take the place of the Cass County society. Meetings will be held alternately in Linden and Jefferson. Dr Charles E Davis, Linden, was elected president and Dr Joe D Nichols, Atlanta, secretary.—The Scurry Dickens Kent Counties Medical Society at a meeting in Snyder, January 11, voted to surrender its charter and ask for a charter embracing in addition Borden, Garza, King and Stonewall counties. Dr William R Johnson, Snyder, was elected president and Dr Harry E Rosser, Snyder secretary.—The Tom Green County Medical Society voted at a meeting in San Angelo Dec 19 1933, to surrender its charter and petition the state association for a charter embracing the counties of Tom Green, Coke, Crockett, Concho, Irion, Sterling, Sutton and Schleicher. The new society, to be known as the Tom Green Eight County Medical Society has as president Dr Washington B Everitt, Sterling City, and as secretary, Dr Wilson D Anderson, Sanatorium.

WEST VIRGINIA

Society News—Drs George H Barksdale and Robert K Buford, Charleston, addressed the Greenbrier Valley Medical Society, Lewisburg, January 23, on digitalis in treatment of heart disease and thyroid disease, respectively—Dr John A Kolmer, Philadelphia, addressed the Academy of Medicine of Parkersburg, March 1, on specific treatment of pneumonia—Drs James S Klumpp and Frank C Hodges addressed the Cabell County Medical Society, Huntington, February 8 on early diagnosis of cancer—Dr Sam M E Simon, Huntington, presented a paper on recent advances in diagnosis and treatment of tuberculosis before the Raleigh County Medical Society, Beckley, February 1—A symposium on cancer was presented before the Kanawha County Medical Society, Charleston, February 27, by Drs John E Cunnaday, McLeod Gillies, Rome H Walker, B H Swint and J Ross Hunter—Dr Archer A Wilson, Charleston, read a paper on Aids in the Diagnosis in Certain Neuropsychiatric Conditions Met in Private Practice before the Marion County Medical Society, January 3—Dr Russell B Builey, Wheeling, addressed the Marshall County Medical Society, Moundsville, January 24 on cancer of the breast—Dr Irvin Stein, Baltimore, addressed the Ohio County Medical Society, Wheeling, March 2, on 'Calcification Studies in Monkey and Man and Their Clinical Application'—Dr Roy R Snowden, Pittsburgh, was the speaker, February 16, on treatment of hyperthyroidism—Drs Albert H Hoge and Richard O Rogers, addressed the Mercer County Medical Society, Bluefield, January 23, on 'Dietetic Management and Diabetes' and 'Diabetic Coma and Treatment,' respectively

GENERAL

Another New Journal—The first issue of the *Review of Gastroenterology*, official organ of the Society for the Advancement of Gastroenterology, appeared in March. The first issue contains nearly 100 pages and the contents include original articles, abstracts of current literature and book reviews. Dr Samuel Weiss, New York, is editor.

Society News—Dr William D Haggard, Nashville, was chosen president elect of the Southeastern Surgical Congress at its annual meeting in Nashville, March 5. Dr Gerry R Holden, Jacksonville, Fla, became president. Dr James R Young, Anderson, S C, was made vice president and Dr Benjamin T Beasley, Atlanta, reelected secretary. Next year's meeting will be held in Jacksonville—The American Nurses' Association will hold its biennial convention in Washington D C, April 22-27, the general subject of discussion will be 'The Changing Order and the Profession of Nursing'.

Carlos Finlay's Centennial—The centennial of the birthday of Dr Carlos J Finlay, who first advanced the theory that mosquitoes were carriers of yellow fever, was observed in several places throughout the world, it is reported. Squares or streets were named in his honor in several cities, including Mexico, Tampico, Guatemala and Paris. A bust was unveiled at Bogota. Books were published in his honor in Mexico and Guatemala, and the Pan American Conference at Montevideo passed a resolution recognizing his achievements. Special commemorative exercises were held December 3, by the Washington, D C chapter of the Pan American Medical Association.

Pacific Coast Surgeons' Meeting—Dr Edward Clarence Moore, Los Angeles, was elected president of the Pacific Coast Surgical Association at its ninth annual meeting in Portland and Gearhart Ore, February 21-24. Drs Park W Willis, Seattle and Le Roy B Sherry, Pasadena, were elected vice presidents and Dr Edgar L Gilcreest, San Francisco, was reelected secretary. Los Angeles was chosen for the 1935 convention. Among speakers on the program were

Dr Casper W Sharples, Seattle, Liver Deaths Following Operation on the Biliary Tract
Dr Verne C Hunt, Los Angeles, Operability of Gastric Lesions
Dr Curle Latimer Callander, San Francisco, Left Duodenal Hernia Its Mechanism
Drs Albert J Scholl Jr and John C Ruddock, Los Angeles, Peritoneoscopy
Dr Raymond E Watkins, Portland Ore, Carcinoma of the Female Genital Organs

Dental Education—Eight schools of dentistry in the East and Middle West have recently formed the Association for the Advancement of University Education in Dentistry. The newly formed body announces as its aims the fostering of the rational integration of dental with medical education, development of science of dentistry and mutual improvement of the subscribing schools. It advocates two years of pre-dental education and four of professional training and its membership is restricted to schools now operating under that plan or those that have

publicly announced the adoption of the two-four year plan and the approximate date when it will be put in operation. Members of the association are University of Buffalo School of Dentistry, Columbia University School of Dental and Oral Surgery, Harvard University Dental School, University of Illinois College of Dentistry, Ohio State University College of Dentistry, Thomas W Evans Museum and Dental Institute, School of Dentistry, University of Pennsylvania, Tufts College Dental School and Western Reserve University School of Dentistry.

Medical Bills in Congress—*Changes in Status* S 2455, to increase the efficiency of the Medical Corps of the Regular Army has been reported to the Senate with amendment (S Rept 510). It provides that for purposes of promotion there shall be credited to the officers of the Medical Corps all active service as officers of the Medical Reserve Corps rendered by them between April 23, 1908, and April 6, 1917. S 2526, to pay an annuity to Frances Agramonte, the widow of Dr Aristides Agramonte, a member of the yellow fever commission, has passed the Senate. S 2571, authorizing the Secretary of the Interior to arrange with the states for the education medical attention relief of distress and social welfare of Indians has been reported to the Senate, with an amendment (S Rept 511). S 2660 has been reported to the House, with amendments (H Rept 1037). This bill, which has already passed the Senate, proposes to regulate broadcasting from a studio located in the United States through a radio station in a foreign country whose "emissions" are received consistently in the United States.

Bequests and Donations—The following bequests and donations have recently been announced:

Menorah Hospital, Kansas City Mo., \$25,000 given by Mr Edgar L Berkley in memory of his parents.

Presbyterian Hospital, New York, \$30,000 by the will of Mrs Lucy W Denny.

Mount Sinai Hospital, New York, \$2,500 from the estate of the late Dr Alexis V Moschowitz, also his books and instruments.

Children's Hospital, Boston, \$10,000 by the will of Irving Richardson, Brookline, Mass.

St Vincent's and Presbyterian hospitals, New York, \$10,000 and \$7,000 respectively under the will of the late Walter J M Donovan.

United Hospital, Port Chester N Y, \$5,000 by the will of the late W M Craft, White Plains.

New York Homeopathic Medical College, \$15,000 by the will of the late Frances Ogden Jones.

Temple University Hospital, Philadelphia, will receive \$350,000 left by Mrs Etta Mellier.

Jefferson Medical College, Philadelphia, received a bequest of \$25,000 contingent on the death of four heirs from the estate of Mrs Frederick A Hoffman as a memorial to her husband the late Dr Clarence Hoffman who was associated with the college for twenty-five years.

Philadelphia Institute for Medical Research, \$15,000 for study of nervous and mental disease. Jefferson Hospital, \$5,000 for a free bed and Philadelphia Home for Incurables, \$2,000 under the will of the late Mrs Kate Rambo.

Jasper County Hospital, Rensselaer, Ind, \$5,000 by the will of W B Austin.

William S Major Hospital, Shelbyville, Ind, \$100,000 under the will of John A Tindall.

Stuyvesant Square and St Luke's hospitals, New York, \$10,000 each under the will of the late Mrs Mary Helena Tompkins. St Luke's will also receive the residue of the estate.

Mount Sinai Hospital, \$5,000. Montefiore Hospital, \$3,000. New York Eye and Ear Infirmary and Hospital for Joint Diseases, \$2,000 each by the will of the late Richard Sidenberg.

Hospital for Ruptured and Crippled, \$25,000 under the will of the late Mrs Velma B Woolworth.

New York Hospital, \$100,000 by the will of Edward W Sheldon.

Caledonia Hospital, Brooklyn, \$25,000 by the will of the late Alexander Walker.

American College of Physicians—The eighteenth annual clinical session of the American College of Physicians will be held in Chicago, April 16-20, with headquarters at the Palmer House. General sessions at which more than sixty formal papers will be read are scheduled for each afternoon and Monday and Tuesday evenings. The annual convocation will be held Wednesday evening, April 18, when Dr George Morris Piersol, Philadelphia, will deliver the presidential address and Dr Albert Grant Fleming, director of the department of public health and preventive medicine of McGill University, Montreal, Que, will give an address on 'The Medical Aspects of National Health Insurance'. Beginning Tuesday, mornings will be devoted to clinics at the following hospitals: Albert Merritt Billings, Children's Memorial, Cook County, Mercy, Michael Reese, St Luke's, Passavant Memorial and Presbyterian hospitals, the Municipal Tuberculosis Sanitarium and the Veterans Administration Facility, Hines Ill. Sessions will also be held at the University of Illinois, Loyola University, Northwestern University and the University of Chicago. The annual banquet will be given Thursday evening, with Dr James B Herrick as toastmaster. Glenn Frank, LL D, president, University of Wisconsin, will deliver an address on 'The Renewal of America'. The annual smoker will be held Monday evening after the scientific meeting. Dr Herrick, general chairman for

the session, Dr Austin A. Hayden, president Chicago Medical Society, and Dr Irving S. Cutter, dean, Northwestern University School of Medicine, will deliver addresses of welcome at the opening session. Special emphasis is to be laid on the following subjects in the scientific program: cardiovascular disease, infectious diseases, metabolic diseases, nervous diseases, hematology, gastro enterology, tuberculosis, pulmonary diseases and pediatrics.

FOREIGN

New Professorship—The *British Medical Journal* announces that a new chair for racial hygiene has been founded in Berlin, with Prof Fritz Lenz of Munich as its first occupant. Professor Lenz has also been appointed departmental director for racial hygiene and eugenics at the Kaiser Wilhelm Institute for Anthropology in Berlin.

Cholera Decreased in 1933—The incidence of cholera in India during the years 1932 and 1933 was lower than at any time in the last sixty years with the possible exception of 1923, according to provisional figures issued by the Health Section of the League of Nations. The provisional number of cases in 1932 was about 70,000 and up to November had not exceeded 80,000 for 1933. Last year the disease actually disappeared from Madras Presidency, where it had been considered generally endemic. In contrast to the severe epidemic of 1932, the incidence of cholera in China was low in 1933. An epidemic has prevailed in the Philippines since 1930, confined to the central archipelago. Provisional figures for 1933 showed that 1,820 cases with 1,238 deaths were recorded from January 1 to December 2.

Health Project in China Schools—A grant of \$12,000 Chinese currency has been made to the Hunan Yale Medical School by the Hunan provincial government to carry on a public health program in the schools of Changsha. Sixteen schools have been chosen as a starting point and it is estimated that 6,000 students will be reached. Health education through lectures, lantern slides, exhibits and habit training classes will be for the students while additional material will be presented to cooperating parents. There will be an annual physical examination of all students, with a monthly checkup in weight and height, a weekly clinic for correction of defects, as far as possible, inspection for infectious diseases and preventive inoculation. Two physicians and four public health nurses will be assigned to the work. The Hunan-Yale Medical School was started in 1914 as a joint enterprise between the Hunan provincial government and Yale in China. The Hunan-Yale Hospital now has 180 beds with a special children's ward, and is equipped to carry on the treatments that may be needed for conditions found in the health examinations.

Personal—Knighthood was conferred on Dr Robert Muir, professor of pathology, University of Glasgow, among the New Year honors bestowed by the king of England.—Dr Henry Albert Harris, professor of clinical anatomy, University College, London, has been appointed professor of anatomy to succeed Prof James T. Wilson, who will retire next October.—Lieut. General Sir Harold B. Fawcett has retired as director general, British Army Medical Service, and has been appointed director general of the British Red Cross Society. The new director general of the Army Medical Service is Major General James A. Hartigan, formerly deputy director of medical services, Aldershot Command.—Dr Walter J. Turrell of the electrotherapeutic department, Radcliffe Infirmary, Oxford, England, recently received the "golden key" awarded by the American Congress of Physical Therapy at its 1933 session, in recognition of his work in electrotherapy. The key was presented by Dr Norman E. Titus, New York, now on a visit to England at a dinner given in honor of Dr Titus by Dr Francis Howard Humphris.—Dr G. P. Wright, lecturer in morbid anatomy and curator of the Museum at University College Hospital Medical School, has been appointed to the Sir William Dunn chair of pathology tenable at Guy's Hospital Medical School.

CORRECTION

Pimento Peppers—In a query and minor note published in *THE JOURNAL*, March 10, page 790 on Pimento Peppers, the second paragraph should read as follows: Pimenton is large pepper, otherwise Cayenne or red pepper. Pimenta is 'pepper' specifically black pepper. Pimiento is 'capsicum or pepper'—as the fruit of the pepper. In view of the confusion between pimento (allspice) and pimiento (sweet pepper) it makes for clarity to designate the Spanish sweet pepper as the pimiento pepper or 'pimento pepper'. From a practical horticultural point of view.

The Increase of Deaths from Tuberculosis in Young Women

While a great decrease of tuberculosis has taken place in the general population, an increase in deaths from the disease has recently been observed among young women. Various explanations have been suggested. Dr F. J. Bentley, divisional medical officer in the public health department of the London County Council, who has been conducting research into the subject, gives as the chief cause the racket of modern life and the increased strain that young women and girls are called on to bear. Practically the whole increase has been in single women. Dr Bentley's inquiry related to the habits of females from 15 to 25 years of age who were having residential treatment under the council's tuberculosis scheme. He sent a questionnaire to 100 young women who were consumptive and to the same number of healthy young women of the same ages and occupations. On an average the girls in each group did nine hours of work a day and had eight and one half hours in bed, while in the matter of food the consumptives had the advantage. Forty-two per cent of the healthy were smokers, but only twenty-nine of the consumptive. No doubt the difference was due to the advice given to persons with coughs to stop smoking. The prevalent desire for a slim figure among young women has led to the suggestion that reducing is a contributory cause of consumption. Dr Bentley concludes that it is impossible to attribute the increased mortality to any single factor. But who will deny that the stress and strain of modern life have seriously increased during this century? This Dr Bentley thinks has seriously tipped the scales of tuberculosis against young women, always critically balanced and especially susceptible to this disease. One form of stress not mentioned by Dr Bentley, but suggested by previous investigators, is too much devotion to amusements such as the cinema and dances after a hard day's work.

Traffic Accidents in Eight Years

In the house of commons the home secretary gave appalling figures for traffic accidents in the last eight years, during which the number of persons killed was 50,837 and injured 1,421,083. The following is the complete table of accidents circulated.

Year	Killed	Injured	Total
1926	4,686	133,888	138,574
1927	5,790	145,571	151,361
1928	6,198	164,838	171,036
1929	6,696	170,917	177,613
1930	7,301	177,891	185,192
1931	6,691	202,110	208,801
1932	6,667	204,410	211,077
1933	7,120	216,401	223,521
Total	50,837	1,421,083	1,471,920

The Pedestrians Association has sent a memorandum on road safety to the minister of transport, stating that the high speed of automobiles is the main cause of traffic accidents. The association suggests that all vehicles subject to speed limits should be fitted with a device visible to any passer by, which either records the actual speed at any moment or gives audible or visible notice when the limit is exceeded. It has been shown that the majority of fatal accidents take place in built up areas, and the association therefore asks for a speed limit applicable to towns and villages. All negligence resulting in death or serious injury should be punishable. Every new applicant for a license to drive should pass a test for physical fitness, mechanical competence and knowledge of road signs and rules, and

every driver responsible for an accident should be submitted to these tests so that gradually unfit drivers might be eliminated. The association strongly urges that the government take steps to mitigate the hardships suffered by many of the injured in traffic accidents and by the families of the killed, by giving effect to the representations of the committee of the house of lords that an injured person not traveling in an automobile be relieved from the onus of proving negligence on the part of the driver and that more adequate means be provided for securing payment of compensation to the victims of accidents.

A Debate on Silicosis

An important debate on the cause of silicosis took place at the Institution of Mining and Metallurgy. A mineralogist, W. R. Jones, D.Sc., of the geological department of the Royal School of Mines described his investigations of mineral residues from twenty nine lungs of persons whose death had been certified as due to silicosis. Five lungs were from workmen in the pottery industry and twenty one from workers in coal mines. He found that the dust in all cases consisted of minute acicular fibers of sericite (hydrated silicate of aluminum and potassium, which is also called secondary or white mica). The mineral was abundant in all the rocks and materials that gave rise to the dust inhaled. He also found silica in the uncombined state, that is, quartz, but in much smaller quantity than the sericite. He concluded that uncombined silica was not the chief cause of silicosis but that fibrous minerals, chiefly sericite during the operations of drilling, blasting or crushing were set free in the atmosphere as individual fibers and were inhaled in the course of time in sufficient quantity to cause the disease. Whether they acted by mechanical irritation, causing the growth of fibrous tissue or induced chemical changes was a pathologic question outside his province.

Prof. I. S. Haldane dissented. He held that there was clear evidence which incriminated uncombined silica. This never depended on the nature of the dust found in the lungs but on the history of prolonged exposure to dust containing a high proportion of uncombined silica. The danger of crushing pure quartz without precaution against inhaling the dust had long been known. As a physiologist he protested against the idea that the lungs might be regarded as a sort of geological dust trap. By means of the phagocytes and ciliary action dust was continuously removed from every part of the lungs but in the case of pure silica this process failed and at the same time the lungs became susceptible to tuberculous infection. Other speakers supported Professor Haldane's view. Sir John Flett, director of the geological survey who is also a physician considered finely divided silica a highly dangerous substance.

Foreign Medical Students and Practitioners

In view of protests from the medical syndicates, the Conseil supérieur de l'Instruction publique is apparently shelving for the time being, the provisions that the minister of public instruction proposed to control the number of foreign practitioners of medicine. Heretofore such control was based on the Herriot decree and the Armbruster law. The Herriot decree requires naturalization for the transformation of a university doctor's diploma into a government diploma which alone confers the right to practice medicine in France. The Armbruster law requires naturalization before an applicant can practice in France but permits foreigners to take the government examination for the doctor's degree. The minister regarding the provisions of the Armbruster law sufficient was considering the revocation of the Herriot decree but the syndicates quickly discovered what would happen. For the government examina-

tion, wide facilities are accorded. The required period of preparatory study is two years instead of five. Only the final examination is required. If the provisions of the Armbruster law alone were applicable, foreigners holding a university doctor's diploma, and having secured through diplomatic representations its transformation into a government diploma, would wait until they are 30 years old before becoming naturalized. For, after 30, military service is not required of naturalized citizens, and not after 28 if an applicant has children. Attention has been called to the large number of German refugees who are matriculating at the university. After three years of study and having secured the transformation of their university diploma, they need only wait until they are 30 years old to have the right to practice in France, which will give them an advantage over French students, as they will not lose the year devoted to military service. France has already many physicians who can no longer make a living. Nevertheless, the Conseil supérieur has refused to do anything to modify the situation and the number of university diplomas being issued by the faculties of medicine is constantly increasing. Their total has reached 2,616 (1,243 in Paris alone). Of this number, 166 graduates secured later a transformation into a government diploma.

Postdiabetic Insulinemia

Mr. Rathery reported to the Academy of Medicine a typical case of hyperinsulinemia, a syndrome that may be spontaneous, attended with hypoglycemia, and characterized by asthenia, hypothymic manifestations, a sensation of hunger, a feeling of corpulence and the like. Mr. Rathery's patient had been diabetic for nine years but had ceased to be a diabetic for the previous year and could tolerate large amounts of starchy food. For some time past he had presented a condition of spontaneous hyperinsulinism and his blood sugar sometimes dropped to 0.65 Gm. His complete recovery (without insulin) from ordinary diabetes is not exceptional, but the existence of a syndrome just the opposite of diabetes, in a person formerly diabetic but now cured is rare.

Contamination of Rivers by Lead Arsenate

The newspapers have contained accounts of dead fish observed in certain rivers of southern France. On investigation it was found that the action of waste waters from adjacent factories on the river banks could be eliminated, for several of the rivers had no factories on their banks. Mr. Vincent Richard, a chemist in the department of Ain, conceived the idea that the poisonings were due to lead arsenate, traces of which he found in these waters. Lead arsenate forms the base of various products widely used in agricultural regions to combat the animal and vegetable parasites that infest grapevines and fruit trees. The surface waters carry off considerable quantities of lead arsenate, thereby introducing the poisonous substance into the springs and the rivers. Furthermore when the lead arsenate is applied after the blossom of the grape has appeared it penetrates the grape and can be found in the wine, which itself becomes a menace. Mr. Richard reported to the prefect of Ain the results of his observations and added that he had seen cattle die in Morocco that had eaten, along with pasture grass, locusts poisoned by arsenates. He stated also that birds die in large numbers after eating insects poisoned by products with an arsenic base, and that likewise arsenized wheat for the destruction of rats is extremely dangerous. The Comité supérieur d'hygiène publique has been asked to look into this question. The Academy of Medicine has inquired into the matter at various times and has passed a resolution that agriculturists be prohibited from using arsenical products as insecticides. The agriculturists allege that there are no other substances quite so effective and so cheap for this purpose. The resolutions of the academy have consequently been ignored.

Tuberculosis Among the Personnel of Hospitals

Dr Dornedden has obtained data, through an inquiry instituted by the federal bureau of health, on the status of tuberculosis among the personnel of 2,113 hospitals and 716 aid centers for the tuberculous, including more than 80,000 persons from Dec 1, 1928 to Nov 30, 1931. 6,607 persons of these groups (82 per cent) reported sick. Of these cases, 76.8 per cent were with certainty, and a further 14.5 per cent were in all probability, tuberculous. Of the sure cases 89 per cent were active and 42.7 per cent were healed infections. 48.4 per cent of the cases were quiescent. If one considers the large number of quiescent and cured cases, the morbidity incidence of 82 per cent is not particularly high. In the group of physicians examined by specialists and roentgenologists, the percentage of morbidity was 128 or 117 in those more than 50 years of age and in women physicians under 50 years old. 68. The percentage of morbidity in the group composed of the whole personnel (examined in the same manner and comprising 3,682 persons) was 12.33. The morbidity among the personnel of the tuberculosis sanatoriums was the highest but in the group that took care of tuberculous patients in the hospitals and infirmaries it was above the average. It should be considered that tuberculous persons often accept positions in tuberculosis departments. No relative difference in the morbidity could be discovered in keeping with the length of service in such institutions. However the conclusion appears justified that limitations of the working hours and elimination of the more weakly attendants should be instituted. Comparing these with former statistics, it appears that the formerly excessive morbidity of the care-taking personnel, owing to the protective and control measures and the regulation of the working hours has been reduced and now but slightly exceeds the average morbidity of the population as a whole.

Oral Focal Infection

The fact that the majority of the German people are suffering from odontogenous foci furnished the occasion for a recent address by Dr Netter, before the Breslau Medical Society, on oral focal infection in its relation to the whole organism. Oral focal infections may be associated not only with the teeth but also with the tonsils. Infection of the tonsils is frequently the secondary stage of a chronic infection whereas the primary focus lies in the teeth. The tooth is not merely a hard formation that is easily detached from the body but, viewed biologically and genetically, is the nucleus of an organic unit of a higher order. The enamel and dentin and the "tooth bed" form a compact tissue complex, which is attached to the jaw base without demonstrable border. By reason of the close connection of each tooth with the whole organism, pathologic processes of the pulp or the gum line find easy entrance to the body. If inflammation extends from the pulp through the apical foramen into the jaw, it commonly brings about an apical osteitis due mostly to streptococci and less frequently to pneumococci along with other bacteria. The defense forces of the body are often called into action for years and are unable to reach and eliminate the infective agents coming from the frequently symptomless necrotic dental root. Granulomas sterilized by the defense forces of the body are frequently reinfected from the root canal system. Netter has observed 200 cases over a period of eight years, in which, after treatment of the dental foci, in combination with general and special treatment, the organic disturbances (heart, joints, neuralgias, sciatica, and the like) disappeared. Furthermore there disappeared, in numerous cases also acne, herpes labialis and the previous

tendency to colds. Odontogenous focal infections deserve, therefore, in view of the vast number of persons affected, careful attention by those who are endeavoring to raise the general standard of public health.

The Geographic Origin of Professors in Medical Schools

Dr Kivser-Petersen of Jena has completed an inquiry to determine the place of birth, the institution of first habilitation and the present activity of the occupants of chairs of medicine. He reports that of the 390 head professors who are members of medical faculties in Germany, 66 per cent began their academic careers in the city of their birth and 46 per cent in the land in which they were born (Prussia, Bavaria or elsewhere). 38 per cent are at present engaged in their native city and 45 per cent in the land of their birth whereas 84 per cent were born in foreign countries. In the city of their first habilitation there are 22 per cent, some of them having taught elsewhere for a time and then accepted a call to return as occupant of a chair. There are 45 per cent in the land of their first habilitation, whereas 35 per cent began their teaching in a foreign country. The number of professors who habilitated in their native city and are still so located is comparatively small (21 per cent), although 28 per cent are still teaching in the same land in which they were born and in which they habilitated.

Study of Criminal Tendencies in Twins

With the aid of the Bavarian ministry of justice Prof Johannes Lange ordinarium in psychiatry at the University of Breslau was able to investigate the personal histories of more than thirty pairs of twins confined in the Straubing penitentiary. There were thirteen pairs of enzygotic and seventeen pairs of dizygotic twins. Of the thirteen pairs of enzygotic twins, both twins had in ten cases received prison sentences. In fifteen of the seventeen pairs of dizygotic twins only one of the twins had received a prison sentence. Especial interest attaches to the fact that in the case of the enzygotic twins the same kind of crime was committed, while the time the crime was perpetrated was the same for the two twins. A study of their private lives before and during the stay in prison revealed the same habits. In the dizygotic twins, on the other hand, there were fundamental differences.

Instillation of Silver Nitrate Solution

The Prussian minister of the interior has announced that while it may be safe for institutions that use large amounts to keep in bottles a supply of silver nitrate solution for instillation into the eyes of the new-born (Crede method), experience has shown that it is not feasible for the use of midwives, in addition to the menace of contamination there is danger of a stronger solution developing as a result of evaporation, and also a possibility of decomposition. For obstetric use by midwives, outside of hospitals, solutions kept in ampules are advisable. One should see to it that there is no danger of bits of glass entering the eye of the new-born, and that the fluid can be properly dropped, lest too large a quantity be instilled into the eyes.

Professor Doderlein Dispensed from Lecturing

The eminent gynecologist Prof Albert Doderlein, who at the age of 73 is still lecturing in the fulness of his vigor at the University of Munich, obtained his doctor's degree in medicine at that university fifty years ago. Doderlein has been a pioneer in three fields. He was the creator of gynecologic bacteriology. He has developed the gynecologic operative technique to such an extent that he has achieved some of the best results in the operative treatment of cancer. He was one of the first to study in microscopic preparations the action of rays on the cell. He came to abandon almost completely the operative treat-

ment of uterine cancer and confined himself to radiologic treatment. His results have been extraordinary. From April 1 on at his request he has been relieved from the obligation of holding lectures.

JUN 15, 1934

The Congress of Surgery

At the fourteenth Congress of Surgery, held at Pavia under the chairmanship of Prof. Gaetano Fichera, the first topic, "Drainage of the Biliary Tracts," was presented by Professor Uffreduzzi of Turin. Although drainage of the biliary tracts has been done for many years, knowledge of the actual influence that it may exert on the liver is still obscure in some respects. The bile is carried through the biliary tracts under a low pressure, usually estimated at about 20 cm. of water but somewhat variable depending on the condition of Oddi's sphincter. By drainage of the biliary passages is meant an intervention capable of abolishing all tension, both normal and pathologic. One makes a distinction between medical and surgical drainage. Medical drainage may render excellent service but cannot be regarded as a true drainage of the biliary passages, since it has the effect of increasing therein the pressure and induces a marked contraction of the gallbladder, and also of the biliary passages, above the obstruction, if any.

Surgical drainage may be external or internal, depending on whether the bile is carried outside the organism or is conducted to the intestine by a different route than normally.

Internal drainage includes cholecystogastrostomy, cholecystoduodenostomy and cholecystojejunostomy.

Indications for the operation are found in cases with obstruction and increased tension in the biliary passages, usually accompanied by icterus, cases of angiocholitis, without appreciable obstruction of the choledochus, and cases of so-called catarrhal icterus.

The general discussion was participated in, among others, by Professor Alessandri of Rome, who brought out that cholecystostomy does not constitute the ideal form of drainage of the biliary passages, except in emergency cases. In grave infections he prefers cholecystectomy and drainage of the hepatic duct by the Kehr method. Calabresi and Donati pointed out that medical drainage is an excellent method for preparing patients for a surgical intervention.

CONDITIONS DUE TO LESIONS OF THE PARATHYROID

The second topic, "Diseases Due to Lesions of the Parathyroids" was discussed at a joint session with the Società di medicina, by Professor Sisto of Modena and Professor Donati of Milan.

Sisto pointed out that formerly the basis of research in changes in the parathyroids was clinical and anatomopathologic whereas today it is essentially biochemical. The conceptions with regard to hypoparathyroidism have changed, as a rule one no longer assumes that disorders characterized by neuromuscular hyperexcitability, such as chorea, gravidic eclampsia and myoclonia, are ascribable thereto. Tetany is certainly a consequence of suppression of the parathyroids in cases in which these are removed or damaged during operations on the thyroid. There are, however, many cases of tetany in which such conditions do not exist, for example, in tetany of infancy, in posttraumatic tetany, in the idiopathic types of adults or in the types due to hyperventilation, to bicarbonates and to phosphates. In all cases of tetany one encounters alkalosis of the blood, which in parathyroid types is associated with hypocalcemia and an increase of inorganic phosphates. Such alkalosis is today regarded as the fundamental cause of tetany and may or may not be produced by deficiency in parathyroid functioning. Likewise guanidinic toxicosis concerning which there has been much

discussion in recent years, cannot be identified with parathyroprival tetany. The result of the treatment confirms these modern views.

Hyperparathyroidism has become a live topic in recent months. However, it also must be deprived of certain syndromes that are not justly ascribable to it. Experimentally an attempt has been made to produce hyperparathyroidism—first with grafts and more recently by the administration of extracts of the parathyroid glands. But neither grafts nor extracts can completely produce a syndrome of true hyperparathyroidism.

Vitamin D and, in a measure, exposure to ultraviolet rays produce effects similar to those of parathyroid extract. Their use often results in improvement or a disappearance of parathyroprival tetany. Not all the effects of the various preparations of vitamin D (for example, the toxic effects and the metastatic calcifications) are attributable to the vitamin D, for also the secondary products of irradiation of ergosterol come into play.

Recklinghausen's disease occupies at present the first place among the hyperparathyroidal syndromes. This morbid syndrome is recognized today as due to hyperfunctioning of the parathyroids, brought about ordinarily by an adenoma or by hyperplasia of these glands. In every case reported, surgical intervention improved the symptoms but did not effect a complete cure. Sometimes deep irradiation of the region of the neck has been found useful. In the group of hyperthyroidal syndromes some authors have included, of late, morbid types such as chronic ankylotic rheumatism. The symptoms on which these authors base their conceptions is the increase of calcium in the blood serum. But their conception will probably be revised.

Professor Donati presented a paper, divided into ten subtitles, on the surgical side of the topic. He stated that parathyroidal osteodystrophia coincides almost completely with Recklinghausen's disease. In certain osteodystrophias, changes of metabolism of alimentary origin, various toxic factors of exogenic origin, and excessive losses of calcium act as pathogenic factors. These conditions are associated with secondary parathyroid hyperplasias, as distinguished from the parathyroid adenoma of osteodystrophia fibrosocistica, they have to do with secondary processes, probably referable to an acidotic factor involving the whole parathyroid apparatus. These factors awaken the suspicion that with the osteodystrophias are associated sometimes changes in other glands of internal secretion, besides the parathyroids. Osteomalacia probably does not have a parathyroid pathogenesis. There may be secondary hyperplasias of the parathyroids that will impose an osteodystrophia fibrosa on the picture of osteomalacia.

The relation between parathyroid osteodystrophia and Paget's disease is not clear. In tuberculosis of the bones, no signs of parathyroid disturbances and in fractures no constant changes in the blood calcium have been revealed. It must be that there is a local mobilization of calcium instead of changes in the general metabolism of calcium. These have been encountered, however, in certain cases of heterotopic calcifications. A study of the relations between the sympathicus and the parathyroids leads to the conception that the regulation of the calcium equilibrium is not associated solely with the functioning of the parathyroids but is of a neuro-endocrine nature.

Fifty-six cases of parathyroid adenomectomy in persons affected with osteodystrophia have been reported. In spite of the existence of such morbid types also in persons that do not have changes of the skeleton, the relation between adenoma and Recklinghausen's disease may be regarded as fully demonstrated. The removal of the tumor in such cases is the proper treatment.

The parathyroid transplant, formerly much used in post-operative parathyroprival tetany, has lost its importance either

because of the more perfect technic of goster operations or because of the possibility of using calcium-vitamin therapy.

Other communications on the subject were presented. Maragliano explained the effect of partial parathyroidectomy on some types of ankylosis polyarthritidis. Alessandri spoke on the results of parathyroidectomy that he observed in fifteen cases. When one does not succeed in separating the individual parathyroids, he advises resorting to regional ligation of the arteries.

BELGRADE

Feb 7, 1934

The First National Health Exhibition

The first national health exhibition was held in Belgrade Aug 19-Sept 20 1933 by the Yugoslav Association for the Protection of the Nation's Health assisted by all state hygienic institutes and by numerous private organizations. The exhibition was visited by a large number of individuals and by schools and similar organizations. Reduced rates were allowed by the railways. The exhibition was divided into two main parts: the first popular and instructive and the second commercial. The following sections were organized: antialcoholic, climatic and bathing resorts, hygiene of mothers and children, the protection of school children, tuberculosis and venereal diseases and malaria and infectious diseases. A special section was devoted to a model hygienic hospital or sanatorium and to showing what private homes, sleeping rooms, kitchens and privies ought to be like. Special attention was devoted to the hygiene of foodstuffs, clothing, places for working and personal hygiene. Finally there was a practical presentation of different kinds of sport and physical training. In the commercial part were exhibited articles needed for personal hygiene: foods, drugs, articles used in dining rooms and a great number of labor saving appliances used in housekeeping. The visitors were so numerous that it was necessary to keep the exhibition open from the early morning until 10 at night. The exhibition board intends to organize a permanent health exhibition.

The Fourth Balkan Medical Week

There are six independent states in the Balkans: Albania, Bulgaria, Greece, Rumania, Turkey and Yugoslavia. Since 1910 Balkan medical weeks have been held each year in a different Balkan state. The first conference was held in Athens, Greece; the second in Istanbul, Turkey; and the third in Bucharest, Rumania. The fourth medical week was held in Belgrade, Sept 11-13, 1933. The subjects on the program were the role of physicians in the Balkan states, the hygiene of children and the sanitary conditions of villages. The largest number of physicians including the vice president of the Union of Balkanic Physicians, Dr. Petre Topa, and the general secretary, Dr. Popescu-Buzen, came from Rumania. Turkey was represented by Professor Dr. Achill Muktar. Dr. Nuretin and Professor Suchelil from Greece; there were Professor Dr. Vladimir Benzis and Dr. Peter Scaramanga, Surgeon General Dr. Ceda Djurdjevic of Belgrade, Dr. Glatzi of Rumania, Dr. Benzie of Greece and Dr. Achill Muktar of Turkey read papers on the role of physicians in the Balkan union. On the hygiene of children there were communications by Professor Ambrozitch of Yugoslavia, Dr. Achill Muktar of Turkey and Dr. Simlja Kostitch of Yugoslavia. On sanitation in Balkan villages a conference was given by Dr. Bojan Pirc of the Central Hygienic Institute of Belgrade. Malaria was discussed by Dr. Ceda Simitch of Yugoslavia, Dr. Achill Muktar of Turkey, Professor Suchelil of Turkey and Drs. Martinescu, Angelescu and Vajanosa of Rumania. The antituberculous campaign in the Balkans was treated by Dr. Trinescu of Rumania and Professor Radosavl-

jevitch of Yugoslavia. The prophylaxis of venereal disease was discussed by Dr. Kitchevatz of Yugoslavia, Dr. Martinescu of Rumania and Dr. Achill Muktar of Turkey. A conference on mental hygiene was held by Dr. Bogitch of Yugoslavia. The Balkan medical weeks not only serve for scientific discussions but have the happy result of creating a friendly atmosphere, which will undoubtedly have a good effect on political relations.

An Expedition to Remote Communities

For the last three years Prof. Dr. George Georgevitch and his co-workers, aided by a private fund, have made during their vacations medical expeditions into different parts of Yugoslavia, especially districts remote from railways or other means of communication. This work is interesting and the number of volunteer physicians is growing every year. This year Professor Dr. Georgevitch has awakened the interest also of professors of history, geology, mineralogy, botany, zoology, archeology and others. Nearly the whole faculty of the university of Belgrade took part in a six weeks' scientific expedition to a mountain district in Montenegro. Cases of chronic diseases, never seen in clinics, were here examined by modern diagnostic methods. The population, having confidence in the well known names of the physicians present, came in large numbers to be examined and to profit by such a rare occasion. The professors and their assistants, although overworked every day, were pleased at having found material which it is impossible for them to see in large hospitals and clinics. An extensive publication will shortly appear on this work. The state is willing to allocate sufficient funds to permit the organization of such medical expeditions every summer.

Death of the Minister of Health

One of the most eminent physicians, formerly minister of health, Dr. Cheda Mihailovitch, has died in Paris of anthrax. He was born in Belgrade sixty-four years ago and was brought up in France. He was one of the first Serbian physicians to study in France, in whose footsteps the new generations have followed. Beloved among physicians, he was an excellent organizer who knew how to gain the sympathies of everybody. He was appointed during the World War as head of all the foreign medical missions working in Serbia. Since 1920 he has many times been sent on delicate official missions to different parts of Europe and even to the United States. It was during one of these official missions to Poland that he contracted anthrax.

Marriages

GLORIA HAMPTON GARMAN, Chattanooga, Tenn., to Miss Alice Harriette Heibek, at Shepherd Hills, February 6.

EDWARD MARVIN MANN, Mavock, N. C., to Miss Ethelyn Anderson Thompson of Summit, Miss., Dec. 23, 1933.

WILLIAM MAXWELL HITZIG to Miss Candis Hall, both of New York, at New Rochelle, N. Y., March 9.

HELEN HARRISON GIBSON, Akron, Ohio, to Miss Anne Richardson of Sharon, Pa., February 16.

JEFFERSON BIVINS HEIMS to Miss Doris McCollum, both of Morganton, N. C., Dec. 23, 1933.

SILVSTER BERNARD HEWIC to Mrs. Hazel Broderick, both of St. Louis, February 10.

EARLE E. HENSON, Princeville, Ill., to Miss Florence Cummings of Peoria, January 17.

FRANK D. RICHARDS, Dewitt, Mich., to Miss Ruth A. Bleil of Belleville, January 26.

SAMUEL JOSEPH ZAKON to Miss Dorothy Gaylin, both of Chicago, March 11.

CLARA HYMAN to Mrs. Rose Sagner Sachs, both of Baltimore, March 20.

Deaths

Walter Earnest Bates, Davis, Calif., University of California Medical Department, 1881 member of the California Medical Association, past president of the Yolo County Medical Society and Northern California Medical Association, formerly lecturer in hygiene at the branch of the college of agriculture, University of California, resident physician in charge of the campus infirmary, 1908-1932, for five years president of the county board of health, for two years superintendent of St. Luke's Hospital, San Francisco, aged 73, died, February 2, of coronary thrombosis.

Edith Rogers Spaulding, New York, Tufts College Medical School, Boston, 1909, member of the American Psychiatric Association, New England Society of Psychiatry, Association for Research in Nervous and Mental Diseases, American Psychopathological Association and the American Orthopsychiatric Association, for many years affiliated with the psychiatric division of St. Luke's Hospital and the Vanderbilt Clinic, aged 52, died, February 23, of coronary thrombosis.

Harold Wilson, Detroit, University of Michigan Homeopathic Medical School, Ann Arbor, 1886, fellow of the American College of Surgeons, past president of the Wayne County Medical Society, at one time associate professor of ophthalmology and otolaryngology, Detroit College of Medicine and Surgery, for many years on the staff of the Grace Hospital, aged 73, died suddenly February 16, in Birmingham, Mich., of acute dilatation of the heart, following an automobile accident.

Raymond John Sisson, Detroit, Syracuse (N. Y.) University College of Medicine, 1922, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, served during the World War, on the staffs of the Harper Hospital Children's Hospital of Michigan and St. Mary's Hospital, aged 36, died, February 23, in the Massachusetts General Hospital, Boston, of pneumonia, following an operation on the kidney.

James Thomas Watkins, San Francisco, College of Physicians and Surgeons in the City of New York, medical department of Columbia University, 1894, member and past president of the American Orthopedic Association, fellow of the American College of Surgeons, lecturer on orthopedic surgery, University of California Medical School, orthopedic surgeon to the Hospital for Children and the Southern Pacific General Hospital, aged 62, died, February 18.

Lizzie Maud Carvill, Boston, Tufts College Medical School, Boston, 1905, member of the American Academy of Ophthalmology and Oto-Laryngology, American Ophthalmological Society and the New England Ophthalmological Society, fellow of the American College of Surgeons, consulting ophthalmologist to the New England Hospital for Women and Children and assistant surgeon to the Massachusetts Eye and Ear Infirmary, aged 60, died, February 25.

William Howe Merrill, Lawrence, Mass., Medical School of Maine, Portland, 1888, member of the American Academy of Ophthalmology and Oto-Laryngology, New England Ophthalmological Society and the New England Otolaryngological and Laryngological Society, fellow of the American College of Surgeons, ophthalmic and aural surgeon to the Lawrence General Hospital, aged 69, died, February 18, of angina pectoris.

Henry Weitzell Wandless, New York, College of Physicians and Surgeons, Baltimore, 1885, at one time clinical professor of ophthalmology, University and Bellevue Hospital Medical College, served during the World War, formerly consulting ophthalmologist to the Mercy Hospital, Hempstead, N. Y., died, February 17, at Garden City, N. Y., of carcinoma of the stomach.

John Holbrook Shaw, Plymouth, Mass., Harvard University Medical School, Boston, 1892, past president of the Plymouth County Medical Society, served during the World War for many years physician to the public schools of Plymouth, formerly on the staffs of the Jordan Hospital, aged 64, died, February 13, of coronary sclerosis.

Benjamin H. Swain, Ballston, Va., George Washington University Medical School, Washington, D. C., 1906, for many years secretary of the Arlington County Medical Society, county coroner, aged 74, died January 30, in the Alexandria (Va.) Hospital, of complications that followed appendicitis.

Thomas R. Pettway, Austin, Texas, Hospital College of Medicine, Louisville, Ky., 1875, member of the State Medical

Association of Texas, formerly a druggist, past president of the Travis County Medical Society, for fifteen years member of the school board, aged 83, died, Dec. 12, 1933, of pneumonia.

Leon Van Horn, Philadelphia, Jefferson Medical College of Philadelphia, 1896, served during the World War, surgeon to the U. S. Public Health Service, in charge of the immigration health work at Gloucester, N. J., station, aged 67, died, February 21, in St. Agnes Hospital, of Ludwig's angina.

Floyd Patrick Smith, Trenton, Tenn., University of Tennessee College of Medicine, Memphis, 1929, assistant director of the health department of Gibson County, served during the World War, aged 39, died, February 24, in the Methodist Episcopal Hospital, Memphis, of cerebral hemorrhage.

Jeffrey James Walsh, Providence, R. I., Tufts College Medical School, Boston, 1918, also a pharmacist and dentist, formerly member of the city council, aged 51, on the staffs of the Rhode Island State Hospital and St. Joseph's Hospital, where he died, February 14, of pneumonia.

George Xavier Roberts, Chester, Vt., University of Vermont College of Medicine, Burlington, 1896, member of the Vermont State Medical Society, served during the World War, aged 65, died, Dec. 18, 1933, of coronary thrombosis.

James Monroe Wicks, Jamaica, N. Y., Cornell University Medical College, New York, 1905, on the staff of the Jamaica Hospital, Richmond Hill, aged 50, died, January 29, in Miami, Fla., of aplastic anemia.

John Schorb Meyer, Caldwell, Idaho, Central Medical College of St. Joseph, Mo., 1897, member of the Idaho State Medical Association, aged 77, died, January 27, of septicemia, following prostatectomy.

Henry Wilderman, Philadelphia, Medico-Chirurgical College of Philadelphia, 1916, aged 42, died Dec. 20, 1933, of coronary thrombosis, at Bern, Switzerland, while abroad doing graduate work.

John Henry Hedley Scudder, Oakland, Calif., Jefferson Medical College of Philadelphia, 1910, aged 50, died, January 25, of hypertrophy of the heart and sclerosis of the coronary arteries.

Edward Temple Willson, Winter Haven, Fla., Columbia University College of Physicians and Surgeons, New York, 1896, aged 68, died February 21, of coronary sclerosis and arteriosclerosis.

Robert Harold Donnell, San Diego, Calif., Medical School of Maine, Portland, 1901, aged 55, died, January 26, in the Mercy Hospital, of acute toxic polyneuritis and hypertension.

Henry Solomon Stark, New York, College of Physicians and Surgeons in the City of New York, medical department of Columbia College, 1886, aged 71, died, January 31, of heart disease.

Roland Aretus Welch, Bellevue, Mich., University of Illinois College of Medicine, Chicago, 1915, formerly a medical missionary, aged 49, died February 25, of cerebral hemorrhage.

Harold Van Cott, Salt Lake City, Utah, Rush Medical College, Chicago, 1903, member of the Utah State Medical Association, aged 60, died, February 15, of heart disease.

Samuel Wesley Thomas, Melcher, Iowa, Kentucky School of Medicine, Louisville, 1880, member of the Iowa State Medical Society, aged 85, died March 6, of arteriosclerosis.

Mary Lane Mansur, Pasadena, Calif., Hahnemann Medical College and Hospital, Chicago, 1899, aged 77, died, January 12, of coronary occlusion and arteriosclerosis.

John J. Peckham, Los Angeles, Hahnemann Medical College of Philadelphia, 1874, aged 83, died January 19, of arteriosclerosis and hypertrophy of the prostate.

Neil Charles McKinnon, Brougham, Ont., Canada, Victoria University Medical Department, Coburg, 1885, L.R.C.S., Edinburgh, Scotland, 1885, died, January 16.

Constantine I. Sotel, Los Angeles, American University of Beirut School of Medicine, Beirut, Lebanon, Syria, 1911, aged 45, died, January 23.

Benjamin E. Thompson, Stoney Creek, Ont., Canada, University of Toronto Faculty of Medicine, 1891, formerly coroner, died, January 8.

James Bates Bennett, Baltimore, Baltimore Medical College, 1889, aged 65, died January 21, of lobar pneumonia and chronic arthritis.

Edwin F. Guyon, Montpelier, Idaho, Medical College of Ohio, Cincinnati, 1891, aged 80, died in January, at Pocatello, of senility.

Bureau of Investigation

JAD SALTS

Once Sold as a Kidney Cure, Now Advertised to the Obese

When one buys a "patent medicine" one buys a name and not a thing. The thing itself can change overnight, it is the name that remains a fixed quantity. Instance after instance could be cited to show how "patent medicines," while retaining the same name, have completely changed in composition. It is the name of a "patent medicine" on which the property value is built, a name that is invariably protected by a trade mark which gives to the owner what is essentially a perpetual monopoly on it.

'Jad Salts' is a good example of the way in which nostrum-makers either change the composition of their products or change the alleged therapeutic virtues to suit the exigencies of

FAT

people
wanted

To Reduce by Quick, New
JAD Method for 2¢ a Day

Now if you are fat you can eat your fill and yet grow thin—by the new JAD Method of reducing. Indeed, you can lose as much as seven full pounds the first week and look pounds lighter from the very first day.

Just take a little new *Condensed JAD Salts* in a glass of water before breakfast and make two small changes in your diet as explained in the folder that comes with the *Condensed JAD Salts* package. Now try this quick, easy way of taking off fat. **YOU'LL SAY IT'S WONDERFUL.** 30-day supply costs only 60¢ at all druggists. Remember—*Condensed JAD Salts* is urged as a poison banishing agent—to eliminate body moisture and unhealthy bloating—not as a reducing one.

A photographic facsimile greatly reduced of a typical Jad Salts advertisement appealing to the obese. The obvious intent is to make the careless reader—and most advertisements are read carelessly—believe that Jad Salts will reduce weight. A careful reading, however, of the last sentence in the advertisement repudiates that idea.

trade—or both. The Bureau of Investigation gets many letters inquiring about Jad Salts. To quote from typical ones: A woman in New York City writes:

Will you please advise me whether *Condensed Jad Salts* which is advertised on the radio as a safe preparation for weight reduction is harmless?

A physician in Iowa writes:

I have a patient using Jad Salts to reduce and wishes to know the merits or demerits of the same.

From Wisconsin a woman wrote:

Would you please let me know whether Jad Salts are harmful to a healthy person?

For many years Jad Salts was advertised as a cure for kidney disease, and three times the product was declared misbranded under the National Food and Drugs Act because of the false and fraudulent claims made for it. This was in 1923. The government chemists reported at the time that analysis showed Jad Salts to consist essentially of a mixture of sodium

phosphate, baking soda, citric and tartaric acids, with traces of lithium carbonate, potassium bicarbonate and hexamethylenamine. Part of the earlier advertising campaign for Jad Salts attempted to convince the public that meat was the "cause of kidney trouble." Some of the claims made in the older advertising were:

Eating meat regularly eventually produces kidney trouble in some form or other.

Meat Cause Of Kidney Trouble
Meat Injurious to the Kidneys'

We are a nation of meat eaters and our blood is filled with uric acid.

Later the exploiters of Jad Salts dropped their references to meat but continued to advertise the nostrum as a treatment for kidney trouble.

Somewhere around 1930 there must have been a serious slump in the kidney-cure game for about that time the entire advertising appeal was changed and Jad Salts then began to be advertised to the obese. The trend of the new advertising was to give the impression superficially that Jad Salts was an obesity cure. Yet the manufacturers had buried in their advertising, the statement that *The salts are urged purely as a poison banishing agent—not as a reducing.* The change in food does the work." If one analyzes the present Jad Salts advertising it declares in effect that it is quite unnecessary to buy Jad Salts in order to reduce—which, of course, is a fact—but that any reduction must be brought about by cutting down on the food intake. While this is the technical thesis of Jad Salts advertising the obvious intent seems to be to make the public believe that Jad Salts is an obesity cure. In other words while the advertising, in screaming headlines and pictures, puts over the idea that Jad Salts is a reducing remedy, the same copy, *sotto voce*, declares that it is the dieting and not the "patent medicine" that brings about any reduction that may occur. Thus advertisements picturing grossly fat women reduced to sylphlike proportions carry such headings, in large black faced type as:

New Way to Lose Pound of Fat a Day

Look Pounds Lighter in an Hour

'Now Take Off Fat a Pound a Day on a Full Stomach'

With the change of appeal, apparently there went a change in composition. The Jad Salts trade package has long carried what purports to be a qualitative statement regarding the alleged ingredients. Comparing the old with the new we find that the only alleged difference between the Jad Salts of today sold for obesity and the Jad Salts sold a few years ago for 'kidney trouble' is that the trace of hexamethylenamine that they used to have in it has been dropped, as has also the baking soda. Otherwise if the trade package is to be believed, the composition is the same. Thus:

FOR KIDNEY DISEASE

Tartaric Acid
Citric Acid
Lithium Carbonate
Sodium Phosphate
Potassium Bicarbonate
Table Salt
Baking Soda
Hexamethylenamine

FOR OBESITY

Tartaric Acid
Citric Acid
Lithium Carbonate
Sodium Phosphate
Potassium Bicarbonate
Table Salt

Still more recently the Jad Salts concern has put out a product that it calls 'Condensed Jad Salts.' According to the trade package, this contains the following substances:

Tartaric Acid
Citric Acid
Sodium Phosphate

Glauber's Salt
Magnesium Carbonate
Baking Soda

Here, then, we see, sold under what is essentially one name, three different products. It seems evident that the regular Jad Salts now being advertised to the obese, while a saline laxative, is an extremely mild one. The *Condensed Jad Salts*, by the addition of Glauber's Salt, is presumably more drastic.

One may assume that if the exigencies of the "patent medicine" business require further changes, we may find Jad Salts undergoing still a further transfiguration both in composition and in therapeutic claims and find it advertised for pathologic states not yet thought of. When one buys a "patent medicine" one buys a name—not a thing.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

HYPERSENSITIVENESS TO LIGHT

To the Editor—I am attempting to treat a chronic skin disorder that is apparently an allergic manifestation of purely physical origin. The patient a man of 54 has suffered with an eczematoid eruption involving only the exposed surfaces of his body for eight years. The lines of demarcation between the affected and the normal skin are clear cut at the collar level on the neck and at the cuff level on the wrists. He is much worse during the summer months than during the winter and even a short exposure to the sun produces an intense itchy reaction. He is fairly comfortable on dark, cloudy days; his skin will blister readily on a few minutes' play of the sun but without typical sunburn. He has been studied minutely and exhaustively, including cutaneous tests with food and contact proteins. There is no suggestion of pellagra. He has tried numerous diets. Dermatologists have treated him with ultraviolet radiation which invariably makes him worse. That he is sensitive to such rays I have proved by mild exposure of a small area of uninvolved skin and I believe that the ultraviolet rays of the sunlight are the essential offending factor. The difficulties of treatment are obvious. It is not practical to keep him in a darkened room the remainder of his life and gradual exposures to the light seem to effect no tolerance whatever. I am wondering whether there is some substance which when incorporated in a simple base and applied as an ointment might remove the penetration of the ultraviolet rays mindful that even the milder ointments irritate his skin. The only benefit noticed from local applications has been transient relief of the intense pruritus. Please omit name.

M D Georgia

ANSWER—This is an undoubted instance of hypersensitivity to light, of which several reports have been recently made by Duke, Sellen, Weiss and others under the designations of urticaria solare, eczema solare, prurigo solaris and light allergy. In the older literature the cases of light sensitivity are described under the two most common terms of summer prurigo and hydroa vacciniforme, the former being used to designate the milder cases of eczematoid and urticarial reaction and the latter for instances associated with vesicles and bullae.

It is interesting to know that as far back as 1862 Bazin described cutaneous reactions due to light sensitivity. For many years it has been known that hematoporphyrin is frequently found in cases of hydroa vacciniforme. Ehrmann (*Arch f Dermat u Syph* 97 75 1909) suggested that this chemical acts as a sensitizing substance and is the cause of the skin eruptions. In 1911 Hausmann (*Biochem Ztschr* 30 276 1911) injected white mice with hematoporphyrin hydrochloride and found that on exposure to sunlight they scratched themselves and their skins became red and edematous. Meyer-Betz (*Deutsches Arch f klin Med* 112 476, 1917) injected himself with hematoporphyrin, with resulting marked sensitivity to light. H L Smith (Buckwheat Poisoning, *Arch Int Med* 3 350 [May] 1909), in discussing a case of buckwheat allergy in man, refers to the general problem of buckwheat poisoning in animals. He says that only white or white spotted animals are affected. If they are kept in the dark no poisoning results. If they are artificially blackened, they escape symptoms. He concludes that sunlight is the exciting cause. He calls attention to the fact that buckwheat contains phytoporphyrin, a derivative of chlorophyll which closely resembles, chemically, hematoporphyrin and mesoporphyrin. Low (Anaphylaxis and Sensitization, Edinburgh, W Green and Son, 1924) says that a substance similar to the phytoporphyrin found in buckwheat may occur in ordinary wheat or oatmeal and may be responsible for some cases of light dermatitis. Among other conditions that are apt to cause hematoporphyrinuria are sulphonal ingestion, liver insufficiency, particularly due to syphilis or alcohol, congenital functional or organic defects of the liver, and lead poisoning. Some doubt has been thrown on the incrimination of porphyrin as a cause of light sensitivity by the experiments of Templeton and Lunsford (*Eczema Solare and Porphyrin* *Arch Dermat & Syph* 25 691 [April] 1932). Following the finding of porphyrin in two cases of eczema solare, these authors exposed eleven non-light-sensitive individuals to ultraviolet irradiation and were able to demonstrate porphyrinuria in all of them. They are of the opinion, therefore, that porphyria is probably a result rather than a cause of dermal sensitization. The internal administration of quinine acriflavine hydrochloride and other fluorescent substances has been reported to increase the sensitivity to light.

It is suggested that the patient be examined for hematoporphyrin and if it is found a search for the possible etiologic factors suggested be made with particular reference to sulpho-

nal, lead poisoning, liver insufficiency and buckwheat ingestion. If this is of no avail, the use of hydrochloric acid orally as suggested by Barber and Howitt may be tried. To diminish the penetration of ultraviolet rays, several substances have been suggested for local use. Disodium naphthol sulphate probably offers the greatest possibility of success along this line. This may be incorporated in an ointment base to the extent of 5 per cent. If an ointment is undesirable, a 5 per cent solution in alcohol may be used locally.

WASSERMANN FAST SYPHILIS IN PREGNANCY

To the Editor—For the past six years I have been treating a woman now 30 years old for syphilis intensively in 1928 1930—with mercury and nearsphenamine. In 1931 I gave her six injections of arsphenamine. Her veins got so bad that I had to finish up with nearsphenamine. I continued during 1931 1933 with nearsphenamine bismuth salicylate and mercury with rest periods of from six weeks to three months. I gave her twenty-eight injections of iodobismutol but cannot seem to get the blood Wassermann reaction below 2 plus. Finally a spinal fluid examination revealed a slight increase of globulin (Pandy Noguchi) 9 cells per cubic millimeter and a colloidal gold curve of 2322210000. The spinal fluid gives a negative Kolmer Wassermann reaction. From the report may I assume that my patient is Wassermann fast that the spinal fluid is normal that the cell count and colloidal gold curve can be accounted for by the use of iodobismutol that she can go ahead and become pregnant without fear of syphilitic offspring and that she needs no more antisyphilitic treatment? May I have your views on the matter?

M D Michigan

ANSWER—The first assumption is correct. The patient is Wassermann fast. The other assumptions are false. The iodobismutol cannot be held responsible for the slight increase of globulin, the abnormal cell count and the weak colloidal gold reaction. They indicate an infection of the central nervous system. An examination of the spinal fluid earlier in the course of the disease would in all probability have given a more decided reaction. The patient needs more treatment, courses of foreign protein therapy of some sort and trypanamide being alternated with the ordinary antisyphilitic remedies. The iodides should not be omitted.

After the spinal fluid and blood serum reactions have become wholly negative the treatment can be decreased gradually, but a little treatment should be given each year for a long time, with serologic and clinical examinations at regular intervals with special attention to nervous symptoms or signs.

The danger of infection of the fetus in so old a case after so much treatment is slight, but treatment should be given in all pregnancies for fear of one of the unexpected recurrences that are sometimes encountered. According to eminent authority, pregnancy should be a benefit to the patient in overcoming the syphilitic infection. J H Stokes (Clinical Syphilology, Philadelphia W B Saunders Company, 1926, p 24) writes: "So influential is pregnancy and lactation in reducing the severity of syphilis in women that one might almost speak of the bearing of children as a part of the treatment of the disease." Before deciding on the pregnancy, it would be wise to test the efficiency of the kidneys. Spinal puncture should not be made during pregnancy.

LEAD POISONING

To the Editor—I should like to know whether a man working with sheet lead in the following ways is subject to lead poisoning or to any other industrial disease: 1 Hand forming of bowls and other utensils from sheet lead of the common variety and also sheet lead with 6 per cent antimony. 2 Polishing the same types of lead with steel wool by hand. 3 Lacquering these articles by brushing and by dipping which includes certain fumes caused by a low temperature drying bin. Any information you can give me regarding precautions to be taken in this type of work will be appreciated. Please omit name.

M D New York

ANSWER—1 Probably not. The handling of lead in the form of sheets or ingots rarely leads to lead poisoning. The presence of 6 per cent antimony with the lead is also unlikely to make antimony poisoning probable or to increase the likelihood of lead poisoning.

2 Yes. Polishing lead sheets with steel wool will generate some lead and antimony dusts. Lead poisoning is a reasonable expectancy. Practical protection may be secured by the consistent wearing of a respirator of suitable type. As one example of practical respirators for this operation, mention is made of the Willson No 3 felt bag type.

3 The extent of danger from lacquer vapors primarily depends on the constituents of the lacquer. Rarely are these exactly the same for any two brands of lacquer. At present the most used substances in lacquer are not highly toxic but may cause moderate irritation of the respiratory tract, dermatitis and other ailments. Ordinarily, protection may be secured by the installation of an exhaust system in the drying room.

SODIUM THIOSULPHATE NOT RECOMMENDED IN MERCURIC CHLORIDE POISONING

To the Editor—I am writing for an opinion as to the merits contra indications, if any and any other information as to the use of sodium thiosulphate in cases of corrosive mercuric chloride poisoning. A month ago I was called on to treat a young woman who in a fit of despondency took by mouth two tablets of corrosive mercuric chloride. By the time I could reach her bedside three hours had elapsed and she was in a condition of shock and vomited almost continuously. I washed the stomach with weak soda water, beat up the whites of six eggs into 8 ounces of milk and she succeeded in retaining nearly all of it. I then gave her intravenously $15\frac{1}{2}$ grains (1 Gm.) of sodium thiosulphate, advised that she be kept warm and urged that she be taken to a hospital as soon as possible which would be in the early morning. This was not done because she felt considerably better. The following morning she had a mild diarrhea which cleared up. Do you think the thiosulphate could have accomplished these remarkable results? If so how? What chemical action took place? Last night I was called on to treat a second case of corrosive mercuric chloride poisoning in my office. This patient took one tablet, or $7\frac{3}{4}$ grains (5 Gm.) and I instituted the same treatment within half an hour from the time she took it. She also was in shock and vomiting. Please give me your prognosis. Please omit name and address. M D Louisiana

ANSWER—While sodium thiosulphate is a powerful reducing agent, precipitating, in the test tube, the mercury from a mercuric chloride solution first as mercurous chloride and then reducing it to metallic mercury, no such reaction occurs in a solution of mercury albuminate. In controlled animal experiments on mercurial poisoning, sodium thiosulphate proved of no value as an antidote for mercury that has gained entrance into the circulation (Haskell C C, Henderson, W C and Hamilton, J R. Sodium Thiosulphate in Mercurial Poisoning. *THE JOURNAL* Dec 5 1925 p 1808). The probabilities are that the vomiting saved the patients.

NONSPECIFIC ERUPTION IN SYPHILIS

To the Editor—A man aged 30 presented himself Oct 4 1933 complaining of a rash on the abdomen and thighs. Examination revealed a macular rash quite typical of secondary syphilis. There was no history of a primary lesion. Physical examination was essentially negative with the exception of the rash. The Wassermann and Kahn tests were reported 3+. Treatment consisted of eight doses of neoarsphenamine 0.6 Gm. each with but little effect. Sulpharsphenamine bismuth 0.2 Gm. was then given for ten doses. Following the first few injections there was a decided improvement but after the sixth dose the rash again appeared and began to spread. I then changed to arsphenamine 0.4 Gm. doses of which he has now had three injections with but little effect. The rash now involves the trunk and both thighs. The Wassermann and Kahn tests are now reported 4+. Treatment is well tolerated. I would greatly appreciate any suggestions you can make regarding treatment. Kindly omit name. M D Michigan

ANSWER—It is a not infrequent occurrence that an individual with a positive Wassermann reaction of long standing may develop a cutaneous eruption that is not syphilitic. A macular rash in the absence of a history of a recent primary lesion is probably not syphilitic. From the data at hand and especially the failure of vigorous antisyphilitic therapy to cause the rash to disappear, one must think of other macular eruptions, such as pityriasis rosea, pityriasis lichenoides, chronic dermatitis medicamentosa or toxic erythema. A biopsy would assist in establishing the macules as syphilis histologically. In view of the questionable character of the eruption it would appear to be safer to withhold further antisyphilitic treatment until the correctness of the diagnosis has been established. Some nonsyphilitic macular eruptions such as pityriasis rosea will disappear spontaneously in the course of a few weeks and are only slightly influenced by treatment. Mild doses of ultraviolet radiation might be of assistance.

INSULIN HYPOGLYCEMIA

To the Editor—Will you kindly give me the main facts on the toxicity of insulin? Is insulin shock with the coma and hypoglycemia resulting from administration of insulin without food intake often fatal? If so in what dosage? Please omit name. M D Washington

ANSWER—Hypoglycemia due to insulin ("insulin shock") is rarely fatal. A fatal case is news, thus one such was reported in the daily press from Russia. In all perhaps only ten cases have been reported despite the fact that insulin is often used carelessly. One patient while in "insulin shock" but mistaken for diabetic coma, was given 30 units of insulin and shortly after another 30 units and died a few hours later. A child seen in insulin shock, likewise thought to be in diabetic coma was given 200 units of insulin and died the next day. In disease of the myocardium a low blood sugar is supposed to be harmful and may induce an attack of angina pectoris, and it is possible that smaller doses than those mentioned may have caused fatalities. Proof of this is generally unsatisfactory and one

need not fear trouble but, indeed, may secure benefit, if insulin with sufficient carbohydrate is conservatively employed in the treatment of heart disease.

One should distinguish between the toxic effect due to hypoglycemia and that brought about by an interaction between insulin and hypersensitive tissues. The latter results in local redness, swelling, and occasionally urticarial wheals. Such tissue responses have been described by F N Allan and L R Scherer (Insulin Resistance Due to Allergy, *Am J M Sc* 185 815 [June] 1933, Insulin Allergy, *Endocrinology* 16 417 [July Aug] 1932). There are few, if any, fatal cases on record.

SECONDARY PAPULOPUSTULAR SYPHILID

To the Editor—A man aged 35 had a penile chancre six weeks ago and a positive Wassermann reaction. He had one intramuscular injection of a bismuth preparation and one intravenous injection of neoarsphenamine. The injections were given by another physician. About a week later the patient noticed a breaking out of body eruptions appearing first on the scalp then on the arms and legs then on the body, and finally on the face which have persisted. These eruptions are papular and pustular, but mostly pustular and caly. There is no itching. What was the cause of the condition? What to do? Please omit name and address. M D Chicago

ANSWER—This patient has a secondary papulopustular syphilid. He should be vigorously treated with bismuth compounds and neoarsphenamine along the established lines of treatment for early syphilis. One of the following books may be consulted for the clinical manifestations of syphilis and its treatment: *Clinical Syphilology* by Stokes, *Treatment of Syphilis* by Schramberg and Wright, or any of the standard textbooks on dermatology.

EFFECTS OF SODIUM MORRHUATE IN VARICOSE VEINS

To the Editor—Within the last four months I have made use of your lending library files on the subject of treatment of varicose veins by the injection method with special interest in the use of sodium morrhuate. From the library I was unable to obtain the following information: 1. The action of sodium morrhuate as an obliterating agent whether on the vein or on the contained blood. 2. Is the factor in the production of the sclerosis the unsaturated fatty acids in the sodium morrhuate? Please omit name. M D Pennsylvania

ANSWER—1. The action of sodium morrhuate as an obliterating agent is both on the intima of the vein and on the contained blood. Injury to the endothelial cells lining the vein is the first factor needed in the production of any thrombosis. 2. In the case of sodium morrhuate it is supposed that this action is produced by the unsaturated fatty acids present plus the alkaline reaction produced by the hydrolytic action on the blood and tissue fluids.

TOXINS FROM CARCINOMATOUS GROWTHS

To the Editor—Would you kindly inform me on how I may secure information as to whether or not toxins have been produced by malignant tumors grown outside the body? If so have the toxins been analyzed from a chemical standpoint? ISADORE GIVNER M D New York

ANSWER—There is little positive information concerning this subject available in the literature. An excellent presentation can be found in Ewing's *Neoplastic Diseases*.

FIBROSIS UTERI

To the Editor—In *Queries and Minor Notes* in *THE JOURNAL* February 24 page 639 Dr Lawrence Parsons of Reno Nev. inquired as to the pathology of fibrosis uteri. Permit me to state that in the experience of the laboratory of the Long Island College of Medicine the specimens universally show adenomyosis interna. In the larger uteri this is especially pronounced in the smaller uteri the basal layer of endometrium is seen encroaching on the underlying muscle fasciculi. A review of the older specimens in our museum collection previously designated as fibrosis has confirmed this finding. The clinical symptom of bleeding is the result of these pathologic changes probably initiated by a disturbance in the pituitary-ovarian relationship. SAMUEL A WOLFE M D Brooklyn

RICE FEVER

To the Editor—In *Queries and Minor Notes* in *THE JOURNAL*, March 3 page 716 there was an inquiry from Dr Milosh Kasich of New York regarding rice fever. The answer suggests malaria as the disease referred to but Duglison's Medical Dictionary revised edition (1866) gives rice disease as a synonym for cholera. As cholera swept China around 1820 (if my memory is not too far off) it would be reasonable to suppose that cholera was the disease referred to instead of malaria. Michigan October Examination

Dr J Earl McIntyre, secretary, Michigan State Board of
Registration in Medicine, reports the written examination held
in Lansing, Oct 10-12, 1933. The examination covered 9 sub-
jects and included 60 questions. An average of 75 per cent
was required to pass. Ten candidates were examined all of
whom passed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Rush Medical College	(1932)	(1933 4)*	5
Detroit College of Medicine and Surgery		(1933)*	1
University of Michigan Medical School		(1932)	1
New York University and Bellevue Hospital Medical College		(1928)	1
University of Pennsylvania School of Medicine		(1933)†	1
University of Western Ontario Medical School		(1932)†	1

* These applicants have completed their medical course and will receive
their M.D. degree and Michigan license on completion of internship.

† License has not been issued.

Book Notices

Benign Tumors in the Third Ventricle of the Brain. Diagnosis and Treatment. By Walter E Dandy M.D. Adjunct Professor of Surgery the Johns Hopkins University. Cloth Price \$5. Pp 171 with 120 illustrations. Springfield & Baltimore Charles C Thomas 1933.

This interesting monograph presents a series of twenty-one cases chiefly tumors in the region of the third ventricle, which are a tribute to the courage and surgical expertness of the author. Considering the nature of these tumors, the mortality (33 per cent) has been reasonable and the postoperative results in the survivors must be a source of great satisfaction. One cannot help but wonder at the author's enthusiasm for ventriculography and surgical intervention when, in speaking of these tumors, he states that "their removal by surgical treatment is relatively simple and affords a permanent cure" and, later, "in every case the diagnosis and localization of the tumor can be made with precision and without risk by ventriculography." One remembers the author's own operative mortality, the realization by every neurosurgeon that tumors within this region constitute some of the most difficult cases, that ventriculograms are notoriously difficult of interpretation when the third ventricle is concerned, and that ventriculography is in nobody's hands entirely free from danger.

There are probably few monographs as carelessly written as the present one. Minor errors abound. For instance, on page 12 a previous operation is described as a "cerebral exploration" while on page 16 it is illustrated and described as a "cerebellar incision [sic]. On page 18, figure 14 illustrates a ventriculogram in which both lateral ventricles are outlined by air with the explanatory note that the opposite (left) ventricle was filled by a second injection made on that side, whereas on page 19 it is stated that "it was not necessary to inject the opposite (left) lateral ventricle." On page 29 is the statement that "the lateral ventricle occupied the midline (figure 23)," but reference to this illustration clearly reveals the ventricle to one side of the midline. On page 152 is the incorrect statement "It is generally accepted that the external geniculate bodies are the way stations in the pathways for hearing." And on page 130 one finds "middle" where the "anterior" cerebral artery seems intended.

It would hardly seem necessary to record the numerous other errors of like character. However, one other tendency of the author merits comment. Throughout the book he constantly shifts back and forth between the present, past and past perfect tenses. At times this shift is from paragraph to paragraph, at other times from sentence to sentence. For the most part roentgenograms have been extremely well reproduced, but the frequent retouching and covering up of the interesting parts with lines and lettering makes it impossible for the reader to interpret them.

The discussion of the cases from the ventriculographic and surgical aspects is excellent but some statements may be challenged. For example, on page 154 the statement "Among the cases collected in the literature none were localized during life and none, therefore, were found at operation" is obviously incorrect. The presentation of the histories and neurologic observations contributes little or nothing to existing knowledge and ignores some well established facts, while the discussion of the pathologic nature of the tumors displays a profound ignorance of the microscopic character of the tumors with which the surgeon is dealing. On page 50 is a photomicrograph of a tumor designated an "ependymal glioma." This tumor bears not the slightest resemblance to either normal ependyma or the ependymomas well known to neuropathologists. On page 166 it is apparent that the author is aware

of this fact, but no reason for his obviously erroneous designation is given. In at least one instance (case 2, group II, pp 47 and 161) the author has made a diagnosis of "ependymal glioma" in which the specimen was lost and apparently no microscopic sections were ever prepared. It is always regrettable when a leader in one field, in this instance neurosurgery, attempts to set himself up as an authority in another (neuropathology) about which he obviously knows so little.

There is a brief and incomplete bibliography of the literature. There is no index. The book presents an attractive appearance. All the illustrations have been well reproduced and the typography is clear and pleasing.

Medizinische Praxis. Sammlung für ärztliche Fortbildung. Herausgegeben von Prof. Dr. L. R. Grote, Chefarzt der inneren Abteilung des staatlichen Krankenhauses Zwickau; Prof. Dr. A. Fromme, Direktor der chirurgischen Abteilung des Stadtkrankenhauses Dresden-Friedrichstadt; und Prof. Dr. K. Warnekros, Direktor der staatlichen Frauenklinik zu Dresden. Band VIII. Die Lungentuberkulose. Eine Einführung in ihre Entstehung, ihre Entwicklung und ihre Verlaufsarten. Von Prof. Dr. Hans Dieffen, Leitender Arzt der inneren Abteilung des Landeskrankenhauses des Saargebietes in Homburg. Paper. Price 8 marks. Pp 142 with 1 illustration. Dresden & Leipzig: Theodor Steinkopff, 1931.

This little book has the special merit of bringing together in brief form the numerous German theories on the origin of chronic pulmonary tuberculosis of adults. The multiplicity of these views and the lengthy arguments of German physiologists over complex details have created much confusion in the minds of American readers. Whether this confusion can be allayed even by such carefully compiled summaries as this one is doubtful. The author attempts the almost hopeless task of distinguishing, through a sufficiently comprehensive terminology, the wide variety of forms of tuberculosis of varying progression, on the basis of hematogenous reinfection from lesions of first infection, exogenous reinfection from without, and combinations of these two processes. The numerous interesting, concisely recorded case histories themselves bear witness to the difficulties in determining the origin of the process in individual cases. Yet the work will repay careful reading for the analyses the author has attempted. He devotes a short section to the treatment of pulmonary tuberculosis but, while intending the book for physicians, he is more concerned with presenting the pathologic background.

Operating Room Procedure for Nurses and Internes. By Henry C. Falk, M.D. F.A.C.S. Clinical Professor of Gynecology, New York University and Bellevue Hospital Medical College. With a foreword by Eugene H. Pool, M.D. Second edition. Cloth. Price \$3. Pp 413 with 328 illustrations. New York & London: G. P. Putnam's Sons, 1934.

This should serve as an excellent manual for nurses in training for the operating room service. It likewise may be used as a reference textbook in their graduate duties. The material is well organized in a logical sequence. Starting from the simple arrangement of the operating room, it gives the nurse some understanding of the more common operations. The author has included more recent advances in surgical technique, especially that related to spinal anesthesia and to blood transfusion. The second part considers the various operative procedures in detail sufficient to enable the average nurse to follow the technique of the surgeon. This book also serves the purpose of instructing interns in operating room procedures.

Determination of the Sensitiveness of the Eye to Differences in the Saturation of Colours. By L. C. Martin, F. L. Warburton and W. J. Morgan. XIII Reports of the Committee Upon the Physiology of Vision. Medical Research Council Special Report Series No 188. Paper. Price 1s. Pp 42 with 19 illustrations. London: His Majesty's Stationery Office, 1933.

The most significant result of the work described in this paper is that the existence of white is definable in terms of visual capacity rather than esthetic judgment. White is the sensation corresponding to the stimulus from which the least discriminable steps in purity tend at first to increase in mixtures from white toward color, reaching a maximum and then decreasing as pure spectral colors are approached. In the experiments that were done the maximum discriminable step was reached half way between white and pure color, regardless of the number of steps. Any increase of retinal pigmentation interferes slightly with the results in the cases of blue and purple. In comparing complementary spectral colors representing the least perceptible steps from white toward color

under equally bright conditions, the points obtained could be found to lie on an ellipse with white as its center. The apparatus used in this work is essentially a trichromatic colorimeter described by W. D. Wright, with modifications by the authors. This article is rather technical and is of particular interest to the physicist or physiologist rather than the clinician.

Food Borne Infections and Intoxications. By Fred Wilbur Tanner, B.S. M.S. Ph.D. Professor of Bacteriology and Head of the Department of Pathology, University of Illinois. Cloth. Price, \$5.50. Pp 439. Champaign: Twin City Printing Company, 1933.

Most of the material in this book is covered in books on the same subject by Savage, Jordan and others. No new point of view is presented, but an attempt is apparently made to bring together a large number of bibliographic references. Few if any topics, however, are treated with real bibliographic completeness, and the inadequacy of the index detracts somewhat from the value of the compilation. A few definite criticisms may be made. The author apparently favors a general examination of food handlers in large cities, although the general trend of opinion is against this, as an impossible task. In the chapter on the Salmonella group, the studies of White and of Kauffman on classification might have been profitably included. The style in which the book is written is not very careful or discriminating. "Cases," "et," relative pronouns refer to what they will, and loose phrases, such as "some considerable time" (p 60) are not uncommon. Proof reading should have been better; there are two obvious misprints in the two stage "prefatory statement", proper names are too often misspelled, once at least on the same page (p 121) with the correct spelling, on page 308 the typhoid bacillus is referred to as "Shigella typhi". The verdict must be perhaps useful but not indispensable.

Chirurgie plastique des seins. Par le Docteur Montant et le Docteur F. Dubois. Paper. Pp 43 with illustrations. Paris: Maloine, 1933.

The authors point out that surgery of pendulous breasts exacts not only thorough technical skill but also a certain esthetic sense. Such artistry cannot be acquired from text books but issues from an innate and cultivated talent. The authors believe that necrosis of the nipples may be avoided in many cases by paying due attention to the perimammary vascularization. These operations are exacting and time consuming. Careful dissection, meticulous hemostasis, thorough mobilization and the avoidance of shock must be aimed at. The brochure comprises twenty pages of text, the rest being allotted to pen drawings illustrating the technique of the operation for the relief of mammary pendulosity. The authors offer nothing new. The descriptive matter is a reiteration of the classic Morestin-Passot operation. There are no original thoughts or improvements introduced, unless one considers a pair of large scissors for the removal of fat a contribution to a surgical procedure that was standardized many years ago. The authors suggest two surgeons operating simultaneously, one taking care of one breast and the other working on the opposite side. This seems cumbersome and unnecessary. A two-stage procedure serves the interest of the patient best. Keloid formation is still the *bête noire* of plastic operations on the breasts. It is noted with regret that the authors accord chloroform first place on the list of anesthetics. The work is divided into a foreword, indications for operation, points of technique, and a description of the surgical displacement of the nipple. All in all, the booklet offers nothing new that has not been repeatedly described in standard works on the subject. No credit is given to the numerous surgeons who pioneered in this field.

La durée de la grossesse et ses anomalies. Par Henri Vignes, professeur agrégé à la Faculté. Paper. Price 15 francs. Pp 96. Paris: Masson & Cie, 1933.

This monograph, which is one of a series on practical medical and surgical subjects, deals with the duration of pregnancy and its anomalies. Vignes discusses the known facts and the numerous theories concerning the beginning of gestation, the causes of labor, the signs of fetal maturity, the usual length of pregnancy, premature labor and prolonged pregnancy. He has analyzed the French, German, British and American literature on this subject with his customary care, and for this reason the monograph will prove to be useful as a source of information.

Medicolegal

Unborn Child Entitled to Necessaries of Life—An information was filed against Sianes charging him with violation of section 270 of the California Penal Code, which requires the father of a minor child to furnish necessary food, clothing, shelter and medical attendance. The section, as amended in 1923, provides that "a child conceived but not yet born is to be deemed an existing person in so far as this section is concerned." A demurrer filed on Sianes' behalf was sustained by the trial court, and the state appealed to the district court of appeal, fourth district, California. One of the questions raised by the demurrer was whether a man could be compelled to provide for an unborn child indirectly, when it was impossible to do so directly. The appellate court gave an affirmative answer, quoting with approval *People v Yates*, 114 Calif App (Supp) 782, 298 P 961, in part as follows:

It is obvious that food clothing and shelter cannot be furnished directly to an unborn child. The same is true of medical attendance and other remedial care. Consequently we cannot limit the meaning of necessities in the case of an unborn child to those which can be directly furnished to it, for to do so would deprive the addition made to the section in that respect in 1923 of any meaning or effect—a result which is to be avoided, if possible in construing statutes. [Citations omitted.] We must therefore hold that as to unborn children, the statute contemplates indirect necessities or those which are to be furnished through the mother.

The appellate court, however, because of a defect in the information, reversed the order of the trial court sustaining the demurrer and instructed the trial court to give permission to amend the information so as to correct the fault—*People v Sianes* (Calif.), 25 P (2d) 487.

Malpractice Unsuccessful Treatment as Evidence of Negligence—Ordinarily, no presumption of want of skill or care arises from the fact that treatment by a physician is unsuccessful. There are exceptional cases, however, in which the result of an operation, if unexplained, may warrant an inference of negligence and be a circumstance entitled to consideration by the jury, when coupled with the other evidence. The fact, said the Court of Appeals of the District of Columbia, that treatment of a fracture of the plaintiff's leg was unsuccessful is a circumstance, when considered in connection with the other evidence in the case, tending to show want of skill on the part of the defendant and established a case for consideration by the jury. The trial court erred, therefore, in directing a verdict for the defendant—*Crist v White* (District of Columbia), 66 F (2d) 705.

Workmen's Compensation Acts Death Following Appendectomy Performed Incidental to Herniotomy—The employee sustained a right inguinal hernia from an accident arising out of and in the course of his employment. A herniotomy was performed under local anesthesia, during the course of which the appendix appeared through the incision. The operating physician, who was provided by the employer, informed the employee that the removal of the appendix was a proper and usual procedure under the circumstances. With the patient's consent, the appendix was removed. As the result of the operation, the employee died of acute nephritis and peritonitis. The widow of the employee was awarded compensation for the death of her husband, and the employer and insurance carrier appealed to the Supreme Judicial Court of Maine.

The employer contended that this case is governed by *Dulac* case, 120 Me 324, 114 A 293. In that case, the deceased employee received an epigastric hernia from an industrial accident. He had suffered for some time from an inguinal hernia and decided to have both of these corrected at the same time. With the surgeon who was to operate to correct the condition caused by the accident, he made an independent contract for a new consideration for an operation for the inguinal hernia. As a result of the surgery, death ensued. It was impossible to determine whether one or the other operation or the combination of the two caused the death. Under those circumstances the Supreme Judicial Court of Maine held that it was a matter of conjecture whether the accident was the cause of death, and compensation was denied. These facts, continued the court are different from those involved in the present case.

In the *Dulac* case there were two distinct operations, and two separate incisions were necessary. In the present case, the removal of the appendix was an incident of the hernia operation. The employee had the right to rely on the judgment of the physician and, even though the removal of the appendix may have been unwarranted and a contributing cause of the death, the employer is nevertheless liable. The accident, in spite of the error of the physician, would still be the proximate cause of the death. The appeal of the employer and insurance carrier was therefore dismissed—*Gauvin's Case* (Me), 167 A 860.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Subphrenic Abscess—The technic of Ochsner and Graves of the "retroperitoneal operation" is in part as follows. Under paravertebral block analgesia an incision is made over and parallel to the twelfth rib. The entire twelfth rib is resected subperiosteally. The erector spinae mass of muscles is retracted medially and a transverse incision is made at right angles to the spine across the bed of the resected rib at the level of the spinous process of the first lumbar vertebra. This incision passes through the bed of the twelfth rib and the attachment of the diaphragm. After the diaphragm has been incised, the renal fascia is encountered. This is continuous above and anteriorly with the posterior parietal peritoneum. The kidney is displaced downward by means of the index finger and the infrahepatic space is palpated. In those cases in which an abscess of the right posterior superior space is suspected the peritoneum on the undersurface of the diaphragm can be

separated from the diaphragm by means of the finger. This separation may be carried upward as far as the dome of the liver and should be extended until the abscess is reached. By means of the mobilizing finger the abscess cavity is opened by plunging the finger through the abscess wall which is adherent to the mobilized parietal peritoneum. Large, soft, fenestrated rubber tubes are introduced into the abscess cavity and brought out through the wound. Through this incision, adequate evacuation of abscesses located in the right posterior superior, right extraperitoneal, right inferior, and even occasionally right anterior superior spaces may be accomplished without traversing or contaminating either the pleural or peritoneal cavities. Abscesses located in the right anterior superior, right inferior, left anterior inferior and left superior spaces can be drained extraperitoneally through the anterior abdominal wall. Abscesses of the right inferior space can be drained by the retroperitoneal approach. In those cases in which there are abscesses above the liver, the suppurative process can be approached and drained extraperitoneally without contaminating uninvolved pleura or peritoneum by employing an approach suggested by Chirromont. The authors exemplify the technic of the retroperitoneal operation by the low mortality rate (97 per cent) obtained following its use in thirty-one cases in which they operated. In their analysis of 3,322 cases of subphrenic abscess collected from the literature and fifty personal cases, the authors found that the incidence is higher in men than in women. They give the mortality rates in the personal and collected cases and state that in order to decrease the mortality it is necessary to avoid contamination of uninvolved portions of the pleura and peritoneum during drainage. This can be accomplished best by draining the abscess extraperitoneally.

Injury as Cause of Malignant Tumors—After a study of their 205 cases, Coley and Higinbotham conclude that 1 A single local trauma may be an important factor, probably the determining factor in the development of malignant tumors of all types. 2 Trauma is a causative factor in a larger proportion of cases of sarcoma than of carcinoma, and in a larger proportion of bone sarcomas than of soft-part sarcomas. 3 The interval of time elapsing between the injury and the appearance of the tumor is often much shorter than is recognized by most writers. In the majority of cases the tumor develops within the first month or six weeks of the injury, but in a considerable number of cases it may develop within one or two weeks. The latter cases justify the classification of acute traumatic malignant conditions originally suggested by the English surgeons. The foregoing examples furnish convincing evidence of the actuality of such a condition. 4 While courts and compensation bureaus both in this country and in Europe have generally recognized single trauma as a competent producing cause of all types of malignant tumors, it is only fair to the insurance carriers that each case be studied and judged on its own merits. 5 If the case in question fulfils all the conditions laid down by Segond, a causal relationship between the injury and the tumor must be admitted.

Fundamentals of Internal Medicine Diseases of the Heart W M Yater, Washington—p 291

Encephalography by Means of Thorium Dioxide Sol—Schoenfeld and Freeman present two cases of encephalography in which thorium dioxide sol was used. The great theoretical advantages of colloidal thorium dioxide, in their opinion, are that its use in encephalography does not deprive the brain of its buoyant cushion of fluid, and that its greater specific gravity brings the contrast medium into the most dependent portions of the ventricular system, such as the temporal horns and the floor of the third ventricle, locations that are difficult to demonstrate in cerebral pneumography. These dependent portions also are nearer the sensitized film and are therefore delineated more sharply. The opaque medium escapes along the lymphatic pathways, clearly outlining the roots and peripheral nerves, and is carried eventually to the regional lymph nodes and into the general circulation. When injected into the cisterna magna of animals the cisterns and fluid pathways are plainly demonstrated, and the material is carried off both by the blood stream and along the lymph canals that accompany the olfactory and optic nerves. The material is still visualized in the arachnoid meshes after two months, but in small quantities, and that which was introduced into the ventricles disappears in a few days, only a small amount remaining in the most dependent portions. Animals tolerate the injections well. The authors used about 5 cc of thorium dioxide sol, mixed it intimately with cerebrospinal fluid and then injected it in one case into the left lateral ventricle and in the other into the subarachnoid space over the occipital pole.

Abscess of Lung—Alexander and Haight point out that abscess of the lung following operations about the upper respiratory passages can be frequently prevented by the preoperative correction of poor oral hygiene, by the use of a light anesthesia and a 15 degree Trendelenburg position to prevent aspiration of oral secretions during operation, and finally by the post-operative use of carbon dioxide inhalations and the encouragement of expectoration of any secretions that may have gained entrance to the lower respiratory tract. The frequency with which pulmonary abscess develops after the aspiration of foreign bodies demands that any case of foreign body or of a suspected foreign body that is nonopaque to the x-rays should be treated immediately by bronchoscopy in order to prevent the sequelae that invariably follow delayed removal. In elderly persons with an impaired cough mechanism pulmonary abscess may result from the retention of infected secretions that have been aspirated during sleep. For this reason it is important that faulty oral hygiene should be corrected promptly. Pulmonary abscess may be caused by a variety of organisms, most important of which are the spirochetes and fusiform bacilli of the mouth.

Schilling Differential Blood Count in Arthritis—In a group of 150 cases under observation or treatment for arthritis, Steinberg selected twenty-six for Schilling differential blood count studies because of definite organic observations in the points. Of the twenty-six patients, seven presented hypertrophic arthritis and eighteen infectious arthritis. One patient gave a mixed picture of infectious and hypertrophic arthritis. The youngest member in the hypertrophic group was 53 and the oldest 72 years of age, and in the atrophic group the youngest patient was 21 and the oldest 66. The average age was 38.2 years. The organism was fairly definitely established in seven cases of the latter group. Three were gonorrheal in nature and in four the hemolytic streptococcus was present in the tonsil or in the joint. In the rest the organism was not isolated. The author's results agree with the current literature that there is a definite shift to the left in the Schilling differential blood count in cases of infectious arthritis as compared with hypertrophic arthritis.

Erysiploid Occurring in Bone Button Factory Workers—Lawson and Stinnett describe a condition of erysiploid that occurred among workers in a bone button factory at Buchanan, Va. The bones used are cattle bones obtained from slaughter houses from South America, Europe and Chicago. The factory employs from 150 to 210 workers, including the women sorters and packers. Since the beginning of operations in the factory in Buchanan from late November 1930 to Dec 20, 1931, there have been 210 cases of erysiploid under observation, mostly among the men sawing the bones or cutting out the buttons from the sawed slabs. The infection has started only after some skin injury. A man not associated with the factory became infected through abrasions on the back of his hand while putting bone meal on his yard. An infection occurred on the knee after it had been bruised against a machine, another on the foot from a cut due to a piece of sharp bone that dropped and pierced the shoe. All the others occurred on the hands, except eight further cases, five of which involved the eyes and three the bronchial tubes. After the initial injury the infection as a rule, is apparent on the third or fourth day and may last from fourteen to twenty-one days. A few of the milder cases clear up in nine days. From the point of injury the inflammation gradually spreads, eventually taking in a large part of the hand. Its edges generally are well defined. Sometimes it may clear up in a finger originally infected and then spread down another, in a few cases the process has even gone back down the finger that had previously cleared up. The parts involved are swollen, rather immobile, tender and feverish, and there is much local pain. There seems to be no permanent general immunity nor any permanent local immunity. Many have had repeated attacks in the same hand or even in the same finger. The swelling rarely goes above the wrist. Sometimes there is lymphatic streaking and occasionally enlargement of the epitrochlear, rarely of the axillary, nodes. Some of the patients complained of severe pain in the shoulder on the involved side. A 10 per cent salicylic acid ointment as recommended by Gilchrist seems to help a great deal.

Nutritional Disease of Childhood Associated with a Maize Diet—Williams describes a disease occurring in the Gold Coast Colony in children of either sex between the ages of 1 and 4 years. The disease appears to take from four to twelve months to declare itself. There is a history of deficient breast feeding, and the only supplementary food used is a preparation of maize. The lesions of the skin are extensive, well marked and characteristic. They may be accompanied by slight edema of the extremities. The mucous membranes are often inflamed and ulcerated and the saliva is frequently acid. In the late stages, corneal ulcers are often present. The nervous system shows persistent irritability, but the reflexes are normal. The temperature is irregular and the pulse is rapid. There is no great anemia, and the blood shows no leukocytosis. The Wassermann reaction is negative, and no parasites are to be found in the blood except when there is associated malaria. There is a tendency to vomiting, and in chronic cases wasting may be severe. Diarrhea occurs and becomes persistent in the later stages. The stools show undigested food but no ova or parasites. The liver and spleen may be enlarged. The respiratory system is not necessarily affected. The urine may show a trace of albumin. At postmortem examination nothing characteristic is found except a fatty, almost diffusely liver. There may be some degeneration of the kidneys. The treatment consists in the administration of an adequate diet rich in accessory substances.

Congenital Syphilis in Mentally Defective Children—Paddle examined the blood and cerebrospinal fluid of 402 mostly low-grade mentally defective children. The Wassermann reaction and Memcke macroclarification reaction were done on the blood serum and the Wassermann reaction, the colloidal gold test, the Pandy test and cell estimations were done on the cerebrospinal fluid. Forty-six cases gave various reactions in the blood or cerebrospinal fluid, and 356 were serologically negative. Of the forty-six, thirty-five were considered to harbor congenital syphilis. Two of the 356 cases were, on clinical grounds, also considered congenitally syphilitic, giving a total of thirty-seven cases of hereditary syphilis, or an incidence of 9.2 per cent. The Wassermann reaction in the blood of these children was, in the majority of instances, much more sensitive than the Memcke macroclarification reaction. The reverse appears to be the case in adults. In the group of congenital syphilis twelve children presented abnormal cerebrospinal fluids. The cerebrospinal fluid of five gave strong paretic types of curve, associated with positive Wassermann reactions, increase of cells and protein, but none of these cases

could on clinical grounds be regarded as juvenile dementia paralytica. The cerebrospinal fluid of twenty nine mongols failed to give any type of curve with the colloidal gold reaction. In 60 per cent of the congenitally syphilitic boy defectives there was a marked retardation in the descent of the testicles. This contrasts with 39 per cent in a comparable group of nonsyphilitic subjects.

Cronin Lowe Serum Reaction for Malignant Conditions—Patterson and Adler used Lowe's reaction for malignant conditions in a series of fifty-nine cases, of which twenty were definitely malignant and thirty-five were nonmalignant but pathologic, while four cases remain unclassified because the presence or absence of a malignant condition could not be decided on with certainty. The reaction, according to their observations, was capable of providing the correct result in only twenty-two cases, or 60 per cent.

Relation of Pituitary Gland to Action of Insulin and Epinephrine—Corkill and his associates state that rabbits from which the pituitary has been removed become abnormally sensitive to the hypoglycemic action of insulin and may even develop a spontaneous hypoglycemia, especially when deprived of food for several hours. In animals that exhibit spontaneous hypoglycemia the glycogen reserves are found to be depleted, and this lack of available carbohydrate may be a contributory cause to the fall in blood sugar. The lack of carbohydrate is not responsible for the increased response to insulin, for the latter is observed in animals that have ample reserves of liver glycogen. The increased insulin response is characterized by delay in the return of the blood sugar to the normal level. The hypoglycemic symptoms are usually severe and are relieved only with great difficulty. Injections of epinephrine or of ampoules of pitressin that will usually relieve insulin hypoglycemia in the normal animal have little or no effect in the animal deprived of its pituitary. Animals that are abnormally sensitive to insulin usually exhibit a diminished response to

epinephrine and an increased sugar tolerance. It is suggested that an abnormal resistance of the glycogen reserves to the mobilizing action of epinephrine is a factor in the increased sensitiveness to insulin. The possibility that this stabilization of liver glycogen is consequent on the thyroid degeneration observed after the removal of the pituitary body is being investigated. Young rabbits, which normally deposit liver glycogen as a result of insulin injection, fail to do so when deprived of the pituitary.

Boiled and Raw Milk in Infant Feeding—In order to determine the nutritive value of raw and boiled milk, Morris and Graham fed two apparently healthy infants, aged 8 months and 7 months, on an adequate measured amount of boiled cow's milk for from ten to fourteen days, on the last seven of which the excreta were collected. Thereafter the same amounts of raw milk obtained from the same source were given for a fortnight, the excreta as before being collected on the last seven days. Aliquot samples of the milk were collected for analysis each day during the metabolism periods. The intake and output of nitrogen, fat, calcium and phosphorus in each of the seven-day periods were determined and the retention of each was calculated. The results show lower retentions of nitrogen, calcium and phosphorus during the raw milk period than during the period when boiled milk was given. While one subject was retaining a large amount of mineral during both periods, the retention in the other subjects was practically nil. Nevertheless, even in this subject the substitution of raw milk for boiled milk over a period of a fortnight did not improve the mineral retention as one might have expected, if it is true that raw milk possesses a superior nutritive value. This metabolic picture is one that is presented by the early stages of rickets in infants. The retention of fat was almost the same in the two types of feeding. These observations afford no evidence that the absorption of nitrogenous substances, fat and minerals is diminished by the boiling of milk. As far as these results go there is no evidence to support the idea that the boiling of milk interferes with its usefulness as a food for infants.

Prethoracic Esophagoplasty—Gregoire describes the successful performance of an esophagoplasty in a youth who had an incurable esophageal stenosis. Twelve operative procedures extending over a year were required to accomplish the satisfactory result. The new esophagus was made up of the cervical esophagus, a cutaneous tube and a loop of small intestine. The procedure could be divided into five parts. The cutaneous tube was fashioned from the skin of the thorax, leaving part of the blood supply intact. The second procedure consisted in isolating a loop of small intestine high up pulling this through an incision in the mesocolon, attaching one end to the stomach by a side to end anastomosis and drawing the other as high up the thorax as possible. The continuity of the intestine was restored by end to end anastomosis. The cervical esophagus was freed from its attachments and brought out to the skin of the neck. The upper end of the mediastinal esophagus was closed. About seven weeks later, anastomosis of the cervical esophagus with the cutaneous tube was made. The last procedure, which involved the greatest difficulty, consisted in anastomosis of the cutaneous tube with the upper end of the loop of small intestine previously connected to the stomach. The greatest sources of danger lay in peritonitis and infection of the mediastinum. The eventual functional outcome was good and the lack of peristalsis in the cutaneous tube portion of the neo-esophagus proved to be only a temporary and minor disadvantage. The author feels that the results were so good that risk is sometimes well worth while.

Treatment of Delayed Unions by Perforation of Fragments—Boppe reports three cases (with roentgenograms) in which there was delayed union following fracture of the tibia and fibula. After several months during which good callus formation failed to occur these patients were treated with the electric needle perforation described by Beck. Under local or spinal anesthesia, small fanlike perforations were made into the fragments of ununited bone. Six weeks after the parts had been replaced in plaster casts good callus formation had occurred. The hypothesis is that these perforations form good canaliculi for the ingrowth of new blood vessels. The author feels that this method is often superior to open operation in cases of delayed bony union.

Hemorrhagic Diathesis in Course of Purpura Haemorrhagica—Landau and Heyman describe a case of chronic purpura haemorrhagica (Werlhof's disease) observed in the hospital for three months. The platelet count was at all times low but fell at times practically to zero. In spite of this fact there was no correlation between the signs of active diathesis (purpura and mucosal hemorrhages), the platelet count and the bleeding time. An unusual complication occurred in the form of hemorrhagic encephalitis apparently due to small cerebral hemorrhages. The authors believe that it is the variation in contractility of the blood vessels that compensates for the thrombopenia and causes the hemorrhagic diathesis to become latent.

- *Duodenocholangitis and Lamblia Intestinalis H Stalder —p 106
- Treatment of Migraine W K Frankel —p 109

Duodenocholangitis and Lamblia Intestinalis—Stalder reports the history of a woman, aged 28, who four years previously had complained of an indefinite stomach ache. She had never been in tropical countries, had never had diarrhea, and had never passed blood or mucus. Recently she again had frequent attacks of stomach ache. Pains in the epigastrium occurred independently of the food intake and were cramplike. Examination revealed a slight sensitivity to pressure in the region of the gallbladder. The patient appeared pale, in spite of the fact that the hemoglobin was 89 per cent. Examination of the feces revealed a normal decomposition of fats and carbohydrates, a negative benzidine test, but a considerable number of cysts of lamblia. Withdrawal of gastric and duodenal contents revealed hypacidity of the gastric juice, and the duodenal secretion and the A bile contained masses of vegetative, highly motile lamblia and a few leukocytes. The B bile likewise contained motile lamblia but in much smaller numbers. In two weeks, withdrawal of the duodenal contents was repeated five times, always with the same result. The duodenal tube was used also to introduce a saturated solution of magnesium sulphate and a 0.5 per cent solution of chinoson. The therapeutic results were slight but severe symptoms remained absent for five months. After that the severe epigastric pains recurred and the examination of the duodenal contents revealed that the A bile was free from lamblia but the B and C bile contained large amounts of vegetative lamblia. The treatment was limited to the administration of hydrochloric acid and liquid petrolatum. With this treatment the patient felt comparatively well and was able to work. The author thinks that this case without an exact laboratory examination might have been diagnosed as a functional nervous disorder. He is in sympathy with the efforts of von Bergmann who stresses that the 'perplexity diagnosis' of functional or nervous disorder will become less frequent with more exact organic examination. He assumes that the patient's stomach cramps were the manifestations of a cholecystopathy which according to several investigators are caused by lamblia. He thinks that thorough examinations in patients with symptoms similar to those described will reveal the presence of lamblia in the duodenal secretion or of cysts in the feces more often than is generally assumed.

Variations of Alcaligenes Melitensis—De Antoni describes a case of undulant fever with interesting bacteriologic observations. During the first stage the form R (paramelittensis) of Alcaligenes was isolated, probably through dissociation in the organism of the patient owing to the action of quinine. When the administration of quinine was suspended there was an apparently spontaneous reversion of the bacilli to the S form (melittensis), corroborated by a successful blood culture and by culture from a splenic puncture. During the first stage there was scarcely any specific but a marked indirect agglutination, while during the second stage the specific agglutination was poor. In the third stage Alcaligenes showed complete specific and no indirect agglutination. The author found that paramelittensis is extremely sensitive to indirect agglutination due to heat peptone lactic acid or acriflavine hydrochloride to which melittensis is constantly insensitive. Such substances as lead acetate, pure alcohol, tannic acid in distilled aqueous solution and saturated solutions of magnesium sulphate and of ammonia, which coagulate mucin, have a specific agglutinating action on the paramelittensis. The R form of the bacillus does not remain stable. Sometimes after cessation of

the quinine treatment it becomes apparent that not all the strains of melitensis are transformable into paramelitensis. There is, however, a gradual progressive return of the micro organism to the S form. This return is marked by a proportionate increase of the antimelitensis agglutinating rate of the blood serum. The author has shown in his experiments that the rapidity of the transformation of melitensis into paramelitensis is always directly proportional to the degree of virulence of the culture. In the author's blood culture, the serum of the patient containing agglutinin is found in strong concentration (10 cc of blood in 50 cc of broth). Of three blood cultures made in one patient, the micro organisms have been dissociated only in the one in which the blood was least rich in agglutinins. The rate of agglutination was 1:200 at the time of the first blood culture, 1:800 at the time of the second, and from 1:800 to 1:1,600 at the time of the splenic culture.

Insufficiency of Suprarenals Caused by Emotion— Bonorino Udaondo and Gonalons say that the study of emotion as an etiopathogenic factor of several diseases has been neglected. Emotion has been considered the cause of mental diseases since olden times. There are also some cases reported in which emotion was the cause of cardiac disturbances and skin diseases. The authors describe a syndrome of insufficiency of the suprarenals caused by emotion of either intense and unexpected or depressive, slow and continuous type. They have observed the syndrome in about fifty adult patients of both sexes. The syndrome is characterized by pigmentation of the skin, melanoderma and cardiac, digestive, thermoregulatory and kinesthetic disturbances. The administration of extract of the suprarenal cortex has always been followed by the disappearance of the syndrome.

Diagnosis of Syphilis from Dried Drop of Blood— Dahr employed Cheviak's method with 600 specimens. A drop of blood is put on a slide stirred for one minute and thus defibrinated, then exposed to the air and dried. It is best to examine the specimen immediately after it has dried but it is still suitable for the test several days later. To the dried drop 0.015 cc of a solution containing 35 per cent of sodium chloride and 0.3 per cent of sodium carbonate is added. The blood is diluted by stirring with this solution and is placed in a paraffin ring (15 cm in diameter) on another slide. Then 0.03 cc of a dilution of the Meinicke clarification extract made with the aforementioned freshly prepared salt solution in a ratio of 1:10 is added. Before use, the extract and diluting fluid are heated separately for eight minutes in the water bath at 56°C (132.8°F), and, after being mixed the solution remains two minutes longer in the water bath. The slide is shaken for about three minutes and kept for thirty minutes in the moist chamber at room temperature, when the reaction can be read. In negative tests the microscope reveals brown granules, but the positive reaction is indicated by black floccules and clots

in the reddish brown fluid. The author calls attention to several sources of error and thinks it advisable to run a known positive and a negative specimen with the sample to be tested, but a negative control is sufficient. The 600 specimens examined by the author were controlled by the Kahn, Meinicke clarification and Wassermann tests. The results harmonized in over 98 per cent. The author thinks that this method is of great value for the general practitioner. The easy method of blood withdrawal is helpful particularly in tests on children and obese persons. The use of the dried drop of whole blood and the fact that the specimen can be kept for several days before it is examined make the method suitable for use in colonial countries and where laboratory service is obtainable only at great distances.

Influenzal Pericollitis—Winternitz observed occasionally pericollitis in influenza patients. In most cases it presents the aspects of perityphlitis, but in a number of patients it appeared as a pericollitis of the descending or transverse colon. If the descending colon and the sigmoid are involved, palpation generally reveals the condition but involvement of the transverse colon is more difficult to detect. The inflammation may persist for several days, and it is accompanied by high temperatures. The symptoms of peritoneal inflammation predominate, while the signs of involvement of the mucous membrane of the colon, particularly discharge of mucus, are slight. In spite of this, it cannot be doubted that the pericollitis is usually accompanied by a colitis.

Crossed Hypersusceptibility in Lymphogranuloma Inguinale and Urethritis of Waelsch—Bezecky calls attention to a report by Frei and his associates, which indicated the possibility of a connection between urethritis of Waelsch and lymphogranuloma inguinale. He observed a patient for years who had suffered from urethritis of Waelsch. The urethral secretion of this patient was tested on five patients with lymphogranuloma inguinale and four of them gave a positive reaction, while twelve controls gave negative reactions. In the patient in whom the reaction was negative, the lymphogranuloma was new, and even Frei's antigen gave an extremely weak reaction. The patient with urethritis gave strongly positive reactions with various lymphogranuloma antigens. The anamnesis of this patient revealed nothing that was indicative of a former lymphogranuloma, and the presence of an intra-urethral primary focus of lymphogranuloma could be excluded. The author further mentions several other cases of urethritis of Waelsch, the urethral secretion of all of which yielded an antigen that produced positive reactions in patients with lymphogranuloma. In view of the possibility of relations between the two conditions, it was decided to try the application of convalescent serum from patients with lymphogranuloma in the patients with urethritis, for this treatment had proved effective in patients with lymphogranuloma. The patient received 30 cc of convalescent serum, but no change was noticed. Since from 60 to 80 cc is required in patients with lymphogranuloma, it cannot be asserted that the treatment was a failure. However, as all the available convalescent serum was required for patients with lymphogranuloma, the patient with urethritis was given no further injections of this serum. The author thinks that there is sufficient evidence not to consider the positive reaction with the urethritis antigen in lymphogranuloma as merely a nonspecific reaction. He admits that Frei's transmission experiments in monkeys proved negative and that observations so far do not permit a definite solution of the relationship, but he is

convinced that the crossed hypersusceptibility of the two disorders is worthy of note

Agranulocytosis—Vonkennel states that local infectious processes, the toxic action of which leads to an impairment of the bone marrow, dominate in the development of the disorder. The disappearance of the granulocytes is the first symptom and provides the way for secondary infections. The point of attack for the agranulocytosis is the bone marrow, and this leads under certain conditions to an involvement of the erythropoietic apparatus, to hemorrhagic aleukia and to panmyelophthisis. Complications that resemble agranulocytosis may develop in the course of antisyphilitic treatment with mercury compounds, arsphenamine, bismuth compounds, gold and malaria. This form has been designated symptomatic agranulocytosis, but just as in true agranulocytosis the bone marrow becomes impaired as the result of the toxic action of a chronic infectious process or of the repeated administration of chemotherapeutic substances. The author observed an agranulocytic blood picture in a syphilitic patient who was treated with a gold oil, but otherwise the patient was entirely free from the symptoms of agranulocytosis. The manifestations of the skin and the mucous membranes are of secondary importance, the disappearance of the granulocytes being the primary factor. Intense itching may be a premonitory symptom of granulocytosis. He emphasizes the necessity of frequent examinations of the blood picture in the course of antisyphilitic treatment. If the hemogram reveals an agranulocytic tendency, the chemotherapeutic treatment should be discontinued at once, for, if this is done, there is a possibility of spontaneous cure. In an agranulocytosis that developed in the course of malariatherapy of neurosyphilis, the author obtained favorable results with intravenous injections of dextrose and with intramuscular injections of small amounts of blood.

Intestinal Obstruction in Childhood—Of nineteen cases of intestinal obstruction observed by Anisimova and Mangeym in the last three years, four were due to congenital atresia, three to Hirschsprung's disease, six to invagination, four to strangulation and two to obturation by worms. The most frequent causes of ileus are congenital atresia and volvulus of the intestine, congenital tumors (teratomas), adhesions resulting from fetal peritonitis, abnormal fixation of the mesentery and of the large intestine, Hirschsprung's disease, invaginations caused by Meckel's diverticulum, inflammatory adhesions, incarceration and worms. The recognition of various forms may be difficult. Atresia comes into consideration only during the first days after birth, invaginations predominate between the fifth and ninth months, while obturation by worms is seen in older children. Vomiting, increased peristalsis, meteorism and failure to pass meconium during the first days suggest atresia of the bowel. Sudden onset of pain, blood in the feces, sausage shaped tumor in the right lower abdominal quadrant, and relaxed sphincter suggest invagination. Long existing constipation, meteorism, periodic distention with symptoms of obstruction, followed by evacuations and the palpation of fecal masses in the large intestine are frequently observed in Hirschsprung's disease. Obstruction resulting from strangulation by Meckel's diverticulum or obturation caused by worms is frequently mistaken for appendicitis. Conservative treatment is indicated only in Hirschsprung's disease and in the first few hours of invagination, in which high enemas and massage sometimes accomplish disinvagination. Early operative intervention constitutes the only effective means in all other instances. Laparotomies and evisceration of the bowel are not well borne by children.

Blood transfusion before and after operation as well as infusions of small amounts of physiologic solution of sodium chloride are indicated.

Venography in Study of Varicose Veins of Lower Extremity—Khodkevich and his associates report the application of venography in a clinical study of varicose veins of the lower extremities. Injections were made in seventeen cases of pronounced varicosity in which the Trendelenburg test was positive. The technic consisted of injecting into a vein 20 cc of a 5 to 10 per cent solution of sodium iodide. Serial roentgenograms were taken after each 5 cc of contrast medium was injected. The study of venograms revealed that the superficial venous system of the lower extremity is represented by two sharply contrasted anatomic types. In the one the great saphenous vein is recognizable as a large trunk running the entire length of the extremity and giving off relatively few branches. The other type is represented by a great saphenous vein which at once divides into numerous large branches so that the main trunk cannot always be told from its branches. In still another modification there exists in about 18 or 20 per cent an accessory saphenous vein which runs parallel to the main trunk. The study of the venograms further demonstrated that the venous flow is centripetal, the contrast medium always spreading in that direction both in the main trunk and in the anastomosing branches. The question of how varicose veins compensate for the hydrostatic pressure appeared to be answered by the presence of numerous anastomatic collaterals which serve to remove excess blood and to divide the hydrostatic pressure among many vessels. Thus they constitute a compensatory mechanism. The authors call attention to the fact that the results of operative treatment of varicose veins as revealed in recent statistics are far from encouraging, there being 30.5 per cent of recurrences. They believe that these results can be improved by proper choice of treatment. In type one, the operations of Trendelenburg, Madelung or Babcock are indicated. In type two operative methods are likely to fail and the injection method is indicated. The sclerosing results of the injection method can be studied by venography.

- *Influence of Mercury Salt on Isohemagglutination E. Madsen—p. 136

Ultrashort Wave Therapy—Vernet states that from his practical experience in more than 300 cases and from a critical study of the material of Schliephage and his assistants his impression is that ultrashort wave therapy in many cases accomplishes more than any other treatment is often effective when other treatment has failed and affords an excellent adjuvant for the surgeon in cases of inflammation, often both before and after operation. The indications for the therapy are not yet clearly defined, and close cooperation between surgeon and internist on the one hand and ultrashort wave therapist on the other is required. Roughly, the indications for ultrashort wave therapy are first of all in localized inflammation, particularly the acute, then in neuralgia, myalgia, chronic localized arthritis and arthritis deformans. An important feature of the treatment is its ability to relieve pain. The author finds that the shortest waves as a rule give by far the best results, yet in some cases refractory to wavelengths of 4 meters particularly favorable results have been obtained at 15 or 30 meters. In the main, harmful effects seem to be excluded if the treatment is so weak that only an agreeable warmth is felt. In treatment of pulmonary disorders a certain danger of hemoptysis must be borne in mind and in patients with deficient sensibility the absence of the heat indicator is to be remembered. A short survey of more than 200 of his cases is given.

Influence of Mercury Salt on Isohemagglutination—Madsen concludes from his experiments that in determinations of human blood types Havem's solution must not be used in preparation of blood corpuscle suspensions.
